Effect of organic substances and plant growth regulators on growth of tamarind (*Tamarindus indica* L.) Seedlings

**Khushboo Tandon, PKS Gurjar, Priyanka Gurjar and R Lekhi**

**DOI:** https://doi.org/10.22271/chemi.2021.v9.i1x.11472

**Abstract**

Tamarind (*Tamarindus indica* L.), or Imli is also called Indian Date. It belongs to the family Leguminaceae. The use of plant growth regulators in proper concentration with scarification may regulate growth behaviour in many fruit crops and pre-sowing treatment of growth regulators could lead to increase seed germination and enhancement of seedling growth. Seed, without use of growth regulators showed poor response for germination and its growth. An experiment was carried out to identify a suitable treatment for getting better seedling growth. In the present study seeds were imposed to twelve different treatments i.e., T<sub>1</sub> Control (Soaking in distilled water), T<sub>2</sub> GA<sub>3</sub> @ 100 ppm, T<sub>3</sub> GA<sub>3</sub> @ 200 ppm, T<sub>4</sub> GA<sub>3</sub> @ 300 ppm, T<sub>5</sub> NAA @ 100 ppm for 24 hr, T<sub>6</sub> NAA @ 200 ppm, T<sub>7</sub> NAA @ 300 ppm, T<sub>8</sub> Acid Scarification (HCL 10%), T<sub>9</sub> Cow urine 5%, T<sub>10</sub> Cow Urine 10%, T<sub>11</sub> Cow Urine 20%, T<sub>12</sub> Cow Dung Slurry for 24hr and in acid 30min in Completely Randomized Design with three replications. The results reveal that among the different treatment combination T<sub>3</sub>: GA<sub>3</sub> @ 200 ppm reported the highest plant growth in respect to days required for Girth of stem, Length of seedling, Root length, Number of roots/seedling, Survival percentage of seedlings were as T<sub>3</sub>: GA<sub>3</sub> @ 300 ppm shows highest result in respect to days required for Number of leaves per seedling and T<sub>3</sub>: GA<sub>3</sub> @ 100 ppm shows highest result for days required for Height of shoot.

**Keywords:** *Tamarindus indica*, GA<sub>3</sub>, NAA, cow urine, HCL, scarification, dormancy

**Introduction**

Tamarind (*Tamarindus indica* L.), or Imli is also called Indian Date. It belongs to the family Leguminaceae. It is native to Tropical Africa, particularly in Sudan and also grown well in the tropical and semi-arid parts of India. India is the world’s largest producer of tamarind products. In India, it is cultivated in 49,020 thousand ha area with the production of 1,90,700 MT (2016-17 Spices Board India). The major tamarind producing States are Tamil Nadu, Maharashtra, Karnataka, Andhra Pradesh, Madhya Pradesh and Kerala. It is presently cultivated in home gardens, farmlands, roadsides, common lands and on a limited plantation scale in India and Thailand, where the species is economically important.

Tamarind is valued highly for its pulp used in the preparation of food and beverages for domestic and industrial purposes. The most outstanding characteristics of tamarind fruit is its acidic and sweet taste due to tartaric acid (10%) and reducing sugars (40%). The fruit, both ripe and dry, contains mainly tartaric acid, reducing sugars, pectin, tannin, fibre and cellulose. The whole seeds also contain protein, fat, sugars and carbohydrates. Both pulp and seeds are good sources of potassium, calcium and phosphorous and contain other minerals like sodium, zinc and iron. The acidic pulp is used in culinary preparations such as curries, chutneys, sauces, soups etc. Fruits are having the higher content of protein, vitamin B and tartaric acid.

The use of plant growth regulators in proper concentration with scarification may regulate growth behaviour in many fruit crops and pre-sowing treatment of growth regulators could lead to increase in enhancement of seedling growth. Plant growth regulators like GA<sub>3</sub> and NAA enhance the germination, growth and survival of seedlings. GA<sub>3</sub> induced the synthesis of amylase and other hydrolytic enzymes during the early stages of seed germination. GA<sub>3</sub> controls mobilization of starch which acts as a respiratory substrate leading to immediate enhancement in cell elongation.
Gibberellins also help in enhancing the availability of reserved mineral elements which promote the germination process. The seed soaked in GA3 and NAA. The seed soaked in GA3 and NAA for 12 hours resulted in high germination and shoot length. The germination of tamarind seeds is also accelerated by soaking in 10% cow urine or cow dung solution (500 g in 10 L) for 24 hours, in which germination is occurred more than doubled. The prices of growth regulators have gone sky high so to overcome this crisis some alternatives for growth regulators are easy to access and cheap.

Materials and Methods

The experiment was conducted at nursery area, Department of Horticulture, College of Agriculture, Gwalior (M.P.) under Horticulture unit during 2017-18. The topography of the area was uniform with proper drainage. The soil of the experimental field was sandy loam. The experimental field was located at an altitude of 208 meters above mean sea level 26° 13’ N North latitude and 78° 14’ E longitude. The experimental design selected was Completely Randomized Design. All the treatments were replicated thrice. The treatments as follows:- T0 - Control (Soaking in distilled water) for 24 hr, T1 - GA3 @ 100 ppm for 24 hr, T2 - GA3 @ 200 ppm for 24 hr, T3 - GA3 @ 300 ppm for 24 hr, T4 - NAA @ 100 ppm for 24 hr, T5 - NAA @ 200 ppm for 24 hr, T6 - NAA @ 300 ppm for 24 hr, T7 - Acid Scarification (HCL 10%) for 30 min, T8 - Cow urine 5% for 24 hr, T9 - Cow Urine 10% for 24 hr, T10 - Cow urine 20% for 24 hr, T11 - Cow Dung Slurry for 24 hr for the growth of tamarind seedlings. After this seeds were shade dried for 10min and then sown in Polybags of 12” x 6” (30 x 15) size filled with a mixture of soil, sand, FYM in the ratio of 2:1:1 at 0.5cm depth in 2 cm apart and were kept in the shade house and watered daily till final data were recorded. Growth parameters at definite intervals were recorded to find out the effect of these pre-treatments on Height of shoots, Number of leaves per seedling, Girth of stem, Length of seedling, Length of roots, Numbers of roots/seedling. The data collected during the investigation were analysed statistically by the method of analysis of variance. The significance of various treatments was judged and suggested by R. A. Fisher (1954) applying ‘F’ test.

Results and Discussion

1. Height of shoot (cm)
The height of shoot was recorded at 30, 60, 90, 120 and 150 days after sowing. The significantly maximum height of shoot 9.90, 14.73, 18.47, 30.53 and 41.70 cm respectively were recorded at successive growth stages under the treatment T3 (GA3 at 100 ppm for 24 hr). However, minimum heights of shoots (6.37, 10.07, 14.73, 21.00, and 31.17 cm) were recorded under T0 (Control) see in table no.1. It was due to additional GA3, activated α-amylase which digested the available carbohydrate into simple sugar so that energy and nutrition were easily available to faster growing seedlings. Increase in plant height due to GA3 has also been reported by Babu et al. (2010) [2]. In the seedlings of Cape gooseberry resulted in highest plant height which was due to GA3, promote the growth of the plant by the promotion of cell elongation. The similar result was found by Wanyama et al. (2006) [16], Mishra et al. (2017) [7] and Kumar et al. (2008) [9].

2. Number of leaves per seedling

The present research reveals that the different plant growth regulators, acid scarification and organic substances show significant effect on number of leaves. The maximum mean number of leaves per seedling was observed under treatment T3 (GA3 at 300 ppm) i.e. 3.73, 9.33, 11.00, 15.60 and 23.30. Whereas treatment T0 i.e. 2.97, 5.50, 7.83, 10.70 and 15.73 was recorded minimum number of leaves per seedling at all stages of observations see table no.2. The increase may be due to cell division and enhancing activity of apical meristem which may be promoted by the growth hormones. This similar results has been reported by Mishra et al. (2017) [7] and Pawar V.B. et al. (2010) [9] says that increase in number of leaves might be due to the reason that GA3 helps in invigoration of physiological process of plant and stimulatory effect of chemicals to form new leaves at a faster rate.

3. Girth of stem (mm)

In present experiment different plant growth regulators, acid scarification and organic substances showed significant effect on girth of stem. The data about girth of stem was recorded at 30, 60, 90, 120 and 150 days after sowing. The maximum girth of stem at all stages was observed in T3 (GA3 at 200 ppm for 24 hr) treatment 1.93, 2.60, 2.60, 2.77 and 3.20 mm. The minimum girth was recorded 1.17, 1.40, 1.73, 1.93 and 2.20 mm under treatment T1 (Cow Dung Slurry for 24 hr) see table no. 3. The beneficial effect of GA3 was probably due to cell elongation and quicker multiplication of cells after the germination. These results are in conformity with the findings of Ratan and Reddy (2004) [13], Harshavardhan and Rajasekhar (2012) [4], Chiranjeevi et al. (2017) [3], Vasantha et al. (2014) [3] and Patil et al. (2017) [10] they reported 200 ppm GA3 for 24 hr show maximum stem girth in seedlings of Custard apple, Jack fruit, Aonla, Tamarind and Jamun.

4. Length of seedling (cm) at 150 days after sowing

The present research reveals that, the different plant growth regulators, acid scarification and organic substances showed significant effect on length of seedling. The length of seedling was recorded at 150 days after sowing. Maximum seedling length 67.53 cm was recorded under T3 (GA3 at 200 ppm for 24 hr) which was significantly superior over rest of the treatments. The minimum seedlings length 48.13 cm was recorded under control T0 see table no.4. According to these results we conclude that gibberrellins are well known for inter nodal cell elongation, thereby leading the increase in seedling length. These findings are supported by Munde and Gajbhiye (2010) [8], Patil et al. (2017) [10], Vasantha et al. (2014) [3] and Harshavardhan and Rajasekhar (2012) [4].

5. Root length at 150 days after sowing (cm)

In this study, the different plant growth regulators, acid scarification and organic substances show significant effect on root length at 150 days after sowing. The maximum root length 26.70 cm was recorded under T2 (GA3 200 ppm for 24 hr) which was significantly superior over rest of the treatments on other side minimum root length of 17.13 cm was recorded under control T0 150 days after sowing see table no. 4. It revealed that maximum length and more number of roots observed under the treatments because it absorbed more food material and might be increased the physiological activities of seedlings, which was essential for cell division or cell enlargement or both, because growth of the plant occurs by two processes i.e. cell division by mitosis which add new cells and elongation of already existing cells by enlargement of the vacuoles. This finding was reported by Swamy et al. (1999) [15], Ramteke V. et al. (2015) [12] and Kalabandi et al. (2003) [6].
6. Number of roots/seedling at 150 days after sowing
In the current experiment different plant growth regulators, acid scarification and organic substances show significant effect on number of roots/seedling. Maximum number of 64.87 roots per seedling was recorded under T2 (GA3 200 ppm for 24hr) followed by (62.67 in T3 (GA3 at 300 ppm) whereas, minimum number of 38.97 root was recorded under control T0 see table no.4. Hence, vigorous root growth due to GA3 might have resulted in more production of photosynthesis and their translocation through phloem to the root zone, which might be responsible for improving the root growth. Similar findings were seen by Al-Hawey Shabaq Muhamad Nafea (2013) [1], Suradinata Y.R. et al. (2017) [14] and Patil et al. (2017) [10].

Conclusion
From the present investigation, it was concluded that, Girth of stem, Length of seedling, Length of roots, Numbers of roots/seedling, was noticed in seedling subjected to application of GA3 200 ppm for 24 hr. were as Height of shoots was noticed superior under T1 (GA3 at 100 ppm for 24hr) and Number of leaves per seedling was noticed superior under T3 (GA3 at 300 ppm). Finally, it is concluded that the plant growth regulator (GA3 200 ppm) was found superior over rest of the plant growth regulators and cow urine, under study, which was significantly influenced the growth of seedling It affect significantly all the recorded parameters. As regards GA3 is significantly encourage to growth of tamarind seedlings. GA3 induced the synthesis of amylase and other hydrolytic enzymes during the early stages of seed germination. GA3 controls mobilization of starch which acts as a respiratory substrate leading to immediate enhancement in cell elongation.
