 Ambient Backscatter Assisted Co-Existence in Aerial-IRS Wireless Networks

Sourabh Solanki, Member, IEEE, Sumit Gautam, Member, IEEE, Shree K. Sharma, Senior Member, IEEE, Symeon Chatzinotas, Senior Member, IEEE

Ambient backscatter communication (AmBC) is an emerging technology that has the potential to offer spectral- and energy-efficient solutions for the next generation wireless communications networks, especially for the Internet of Things (IoT). Intelligent reflecting surfaces (IRSs) are envisaged to be a great potential for their applications in the next generation of wireless networks, including the internet-of-things (IoT). The IRSs are comprised of a synthetic array having sub-wavelength passive reflector elements that can adjust the phase shifts of the impinging waves to efficiently steer them towards the destination which in turn can enhance the communication performance. In the context of the future 6G wireless networks, the IRSs can offer higher energy- and spectral-efficiencies with reduced hardware complexity and cost compared to the traditional cooperative relaying schemes [1], [2]. On the other hand, unmanned aerial vehicles (UAVs) are believed to play a crucial role in providing wider wireless connectivity and coverage to the ground users [3], [4]. Due to their mobility and high altitude, UAVs can establish their individual direct line-of-sight (LoS) links with the ground users to counteract blockages and shadowing in the complex urban environment [5].

As such, several efforts have been made to integrate the IRS with UAV to form aerial-IRS networks [6]–[12]. Aerial-IRSs are particularly suitable for small lightweight UAVs which can support limited payloads and, therefore, may not be able to carry heavy radio-frequency (RF) transceivers like the ones deployed at the base stations (BSs) or relays [6]. In addition, it has been observed that the propulsion energy is the major source of energy consumption for UAV, and energy required for communication is negligible compared to it. Increasing payload can significantly reduce the flight time of UAV [5]. Therefore, reducing the payload seems to be one of the possible solutions to improve the flight time of UAVs. To this end, deploying active nodes (e.g., BSs/relays) would consume a lot of energy that can eventually limit the endurance and operational life-time of the UAVs. Thus, employing a passive IRS on the UAVs can save some energy cost. Furthermore, in comparison to the IRS deployed on buildings, aerial-IRS enjoys more flexibility as it can establish the desired line-of-sight (LoS) links and avoid a large power loss. Towards this, the authors in [7] proposed a reinforcement learning based approach to enhance the performance of millimeter wave (mmWave) networks using aerial IRS. In [8], the performance of an integrated UAV-IRS relaying system has been analyzed in terms of outage probability, ergodic capacity, and energy efficiency for three different transmission modes. Lu et al. considered an aerial-IRS enabled relaying method to assist the BS for an extended coverage [9]. It aimed at maximizing the worst case signal-to-noise ratio (SNR) in a targeted area. Further, the authors in [10] considered the application of an aerial-IRS for the anti-jamming communications. The study in [11] investigates the application of UAV-IRS for IoT networks to improve the coverage, reliability, and spectral efficiency. In [12], the placement of aerial-IRS has been optimized to assist the downlink transmission from a high-altitude platform (HAP).

On another front, ambient backscatter communication (AmBC) is an evolving technology that can utilize the RF signals from the ambient BSs, TV towers, or access points, for the transmission without requiring active RF components.
Communication using AmBC does not require dedicated spectrum and thus, offers spectral efficient means for wireless information transmission. Leveraging on the potential of AmBC, various research works have recently focused on this technology\cite{15, 22, 23}. For instance, the authors in\cite{15} introduced a spectrum sharing paradigm for IoT devices based on AmBC. Authors in\cite{16} studied a cognitive backscatter network based spectrum sharing for passive IoT. A symbiotic radio cooperative AmBC has been analyzed in\cite{17} to facilitate the spectrum sharing. The authors in\cite{18} examined the outage perormance in three different paradigms of cooperative AmBC systems. In addition, a few other works have explored the design of IRS-based AmBC networks. A work in\cite{19} considered an IRS-aided backscattering system to realize the reliable communication for IoT applications. In\cite{20}, IRS and AmBC have been utilized to enhance the performance in symbiotic radio systems. To enhance the backscattering links, IRS has been utilized for non-orthogonal multiple access (NOMA) assisted backscatter communication system in\cite{21}. The authors in\cite{22} integrated IRS, AmBC, and wireless powered technologies to support the device-to-device communication. In\cite{23}, a deep reinforcement learning is considered for optimization in IRS-assisted AmBC system. More recently, the authors in\cite{24} have proposed the synergy between AmBC and IRSs by showing that certain functionalities such as medium access control can be outsourced to the programmable wireless environments to simplify the hardware of the AmBC device.

Motivated by the above-mentioned discussion, this paper\cite{25} proposes a novel system design to investigate the potential of combining the IRS, UAV, and AmBC technologies. Specifically, the proposed design considers the application of a cooperative aerial-IRS to help the information transmission from a terrestrial primary source node to its destination. Meanwhile, a secondary system co-exists on the same spectrum by relying on the AmBC assistance. The considered UAV-IRS methodology can provide a wide coverage in ultra-dense environments, whereas, the employment of AmBC augments in the effective usage of the spectral resources.

In contrast to the conventional cognitive radio based spectrum sharing\cite{26, 27}, the co-existence using AmBC primarily differs in two aspects. First, the secondary transmitter (Tag) does not generate its own RF signal, but rather exploits the RF signal of primary transmitter for its information transmission. Second, due to interference from the primary system, the secondary receiver (Reader) relies upon the successive interference cancellation (SIC) to decode its information. This spectrum sharing concept has also been referred to as a symbiotic radio or cognitive backscattering\cite{28}. For such a system configuration, we comprehensively investigate its performance by deriving theoretical expressions for the outage probability (OP) and ergodic spectral efficiency (ESE). Furthermore, we also examine the asymptotic behaviour of outage performance for primary and secondary systems in high transmit power regime. Based on our investigations, we provide various insights into the system design.

**Notations:** We use $\mathbb{E}[\cdot]$ to represent the expectation and $\mathcal{CN}(0, \sigma^2)$ to represent complex normal distribution having mean zero and variance $\sigma^2$. Also, $I_N$ denotes the identity matrix of size $N \times N$, $K_v(\cdot)$ represents $v$-th order modified Bessel function of second kind\cite{29, eq. (8.432.1)}, $E_i(\cdot)$ is an exponential integral function\cite{29, eq. (8.21)}, while $D(\cdot)$ denotes parabolic cylinder function\cite{29, eq. (9.240)}. We also use $f_X(\cdot)$ and $F_X(\cdot)$ to denote the probability density function (PDF) and the cumulative distribution function (CDF) of a random variable (RV) $X$, respectively, and $Pr[\cdot]$ to represent the probability. Finally, $\Upsilon(\cdot,\cdot)$, $\Gamma(\cdot,\cdot)$ and $\Gamma(\cdot)$ denote, respectively, the lower incomplete, the upper incomplete, and the complete gamma functions\cite{29, eq. (8.350)} and $(\cdot)!$ represents factorial operation.

## II. System Model

As shown in the Fig. I, we consider a wireless network comprising a primary system including a transmit node $S$, a UAV-IRS\cite{8}, and a UE on the ground. Secondary system includes a backscatter capable tag/transmitter $T$ and a corresponding reader/receiver $R$. The notion of primary and secondary systems can be inferred as follows. In the considered setup, both primary as well as secondary users can be a part of the same network wherein one has high priority (i.e., legacy primary system) over the other (i.e., backscattering secondary system) and hence they transmit over the same spectral resources to improve the spectrum utilization efficiency.

In this framework, the primary system may be useful to offload the cell traffic using an aerial node to serve a cell-edge user which is beyond the strong coverage of a base station in a macrocell. Whereas, the secondary system can include IoT devices where $T$ can be a sensor node and $R$ an actuator. Usually, IoT devices require less power and generally have low-rate requirements. Owing to the battery-limitations, it is desirable to save the energy in any possible ways to prolong the operational time of the IoT devices. Leveraging the AmBC technology, an IoT node can transmit the signal without having to generate its own RF signal. Additionally, the secondary system can also include energy-limited device-to-device (D2D) communication where backscatter capable node $T$ will be D2D transmitter and $R$ will be a D2D receiver.

Further, the system operates at sub-6 GHz band\cite{30}. Due to either an absent or blocked LoS link for direct transmission between $S$ and $R$, the $S$ seeks assistance from a cooperative node to relay its information. Consequently, an aerial-IRS mounted on a UAV is considered to be deployed for relaying the information of $S$. Aerial-IRS is equipped with $N$ passive reflective elements that can be reconfigured using a controller. For the secondary system, the backscattering capable node $T$ receives the ambient RF signal from UAV-IRS and thereby modulates its own information for the passive transmission towards reader node $R$. The backscattering node $T$ is considered to be a semi-passive device having an internal power source which can support the low-power circuit operations without requiring energy harvesting\cite{17}. Hereby, we assume the cooperation between primary and secondary systems to
To characterize the small scale fading, all the channel coefficients are assumed to be independent RVs whose envelopes follow a Nakagami-\(m\) distribution \([32], [33]\). Let the channels from \(S\) to \(n\)-th IRS element at UAV, with \(n \in \mathcal{N} \triangleq \{1, \cdots, N\}\), and from \(n\)-th IRS element to UE and R, are denoted, respectively, as \(h_{b,n} \sim \text{Nak}(m_{b,n}, \Omega_{b,n})\), \(h_{u,n} \sim \text{Nak}(m_{u,n}, \Omega_{u,n})\), and \(h_{u,r} \sim \text{Nak}(m_{u,r}, \Omega_{u,r})\). The composite channels \([16]-[18]\) from \(n\)-th IRS element to R and UE via T are represented by \(h_{n,t} \sim \text{Nak}(m_{n,t}, \Omega_{n,t})\) and \(h_{u,t} \sim \text{Nak}(m_{u,t}, \Omega_{u,t})\), respectively.

Further, we can represent vectors of the channel coefficients as 

\[
\begin{align*}
\mathbf{h}_{b,u} &= [h_{b,1}, \cdots, h_{b,N}]^T, \quad \mathbf{h}_{u,e} = [h_{1,e}, \cdots, h_{N,e}]^T, \\
\mathbf{h}_{u,r} &= [h_{1,r}, \cdots, h_{N,r}]^T, \quad \mathbf{h}_{u,t,e} = [h_{1,t,e}, \cdots, h_{N,t,e}]^T, \quad \text{and} \\
\mathbf{h}_{u,t,r} &= [h_{1,t,r}, \cdots, h_{N,t,r}]^T.
\end{align*}
\]

As in addition, \(\Theta = \text{diag}(e^{j\varphi_1}, \cdots, e^{j\varphi_N})\) is a phase shift matrix, where \(\varphi_n \in [0,2\pi), \forall n\), is the phase shift by the \(n\)-th element. Nakagami-\(m\) distribution is a versatile model which encapsulates variety of fading scenarios. For example, it can also be used to describe the Rician fading by setting its parameter \(m\) as

\[
|\mathbf{e}_q|^2 
\]

with a constant \(K\), \(|\mathbf{e}_q|^2 \sim \text{CN}(0, \sigma^2_{\mathcal{E}})\) is the additive white Gaussian noise (AWGN). In \([4]\), the second term accounts for the interference from the backscattered secondary transmission. Based on the received signal in \([4]\), the UE decodes its information using the following signal-to-interference-plus-noise ratio (SINR)

\[
\Lambda_E^x = \frac{P_0 \tilde{d}_1 |h_{b,u}^H \mathbf{h}_{u,e} x|^2}{P_0 \tilde{d}_2 |h_{b,u}^H \mathbf{h}_{u,t,e}|^2 + \sigma^2_{\mathcal{E}}}.
\]
On the other hand, the signal received at R can be given by
\[ y_r = \sqrt{P_b \eta_d} b_h^H \Theta_{b,u,t} x_c + \sqrt{P_b \eta_d} b_h^H \Theta_{b,u,t'} x + \nu_r, \]
where \( \tilde{d}_3 = (d_{bu}/d_0) - \alpha(b_u) (d_{ut}/d_0) - \alpha(b_u) (d_{ut'}/d_0) - \alpha(b_u) \), \( \tilde{d}_4 = (d_{bu}/d_0) - \alpha(b_u) (d_{ur}/d_0) - \alpha(b_u) \), with \( d_{ur} = \sqrt{q_r - q_u^2 + \frac{H^2}{r}} \), and \( d_{tr} = |q_i - q_i| \) being the distances between UAV-IRS to R, and T to R, respectively, and \( \nu_r \sim \mathcal{CN}(0, \sigma^2_r) \) is the AWGN. As highlighted earlier, due to cooperation between primary and secondary systems, node R can decode its information \( c \) using SIC [16]–[18]. Specifically, it first decodes the signal of UE while treating the secondary transmission as interference. To simplify this framework, we evaluate two key metrics e.g., OP and ESE. In this subsection, we compute the OPs for both legacy system and backscattering secondary system by deriving their analytical expressions. For the primary system, we consider two different scenarios viz., optimal phase shifts design and random phase shifting at IRS. To simplify the expressions and better understand them, we also derive the asymptotic behaviour of OPs.

### B. Probability of Successful SIC

Recalling that reader node R first needs to decode the received signal from the legacy primary transmission for carrying out the SIC. Basically, the SIC capable receiver at R first decodes the stronger signal from the S and then subtract it from the combined received signal in (6) to finally extract its own information. We can define this requirement for node R as the condition of successful SIC. Mathematically, it is the probability that the SINR \( \Lambda_R^{\tau_c} \) in (7) exceeds a predefined decoding threshold which can be expressed as

\[ P_{sic}(\tau) = \Pr[\Lambda_R^{\tau_c} > \tau] \]

where \( \tau \) is the minimum required threshold to decode the primary’s signal. In the following theorem, we provide the closed-form solution of (7) to obtain the probability of successful SIC.

#### Theorem 1. The probability of successful SIC at R is given by

\[ P_{sic}(\tau) = \frac{1}{N \Omega_{bu} \Omega_{ur}} \exp \left( \frac{-\tau \sigma^2_r}{d_4 N \Omega_{bu} \Omega_{ur}} \right) \times \left( \tilde{d}_3 N \Omega_{bu} \Omega_{ur} + d_4 \Omega_{ur} \right). \]

**Proof.** Please refer to Appendix A. \( \blacksquare \)

The result of Theorem 1 will be utilized to analyze the performance of backscattering secondary system in the subsequent section.

### IV. Performance Analysis of the Proposed AmBC Assisted Co-existence

This section analyzes the performance of the considered framework by evaluating two key metrics e.g., OP and ESE.

#### A. Outage Probability

Under this subsection, we compute the OPs for both legacy primary system and backscattering secondary system by deriving their analytical expressions. For the primary system, we consider two different scenarios viz., optimal phase shifts design and random phase shifting at IRS. To simplify the expressions and better understand them, we also derive the asymptotic behaviour of OPs.

1) **Primary System with Optimal Phase Shifts**

The primary system is said to be in outage if the received SINR \( \Lambda_R^{\tau_c} \) at UE falls below a certain threshold. As such, for a given target rate \( R_p \), OP can be expressed as

\[ P_{op}^{\tau_c}(R_p) = \Pr \left[ \frac{P_b \tilde{d}_4 (b_h^H \Theta_{b,u})^2}{P_b \eta_d (b_h^H \Theta_{b,u})^2 + \sigma^2_r} < r_{th}^{\tau_c} \right], \]

where \( r_{th}^{\tau_c} = 2^{R_p} - 1 \) is a threshold. Hereby, we consider a coherent phase shift design [37] to enhance the performance of primary user UE. In other words, it is assumed that the phase shifts from the IRS elements are adjusted in such a way that the reflected signals are co-phased, i.e., \( \varphi_n = -\angle h_{b,n} h_{n,e} \) where \( \angle x \) indicates the phase of a complex number \( x \). Consequently, we can re-write the OP expression in (11) as

\[ P_{op}^{\tau_c}(R_p) = \Pr \left[ \frac{P_b \tilde{d}_4 \left( \sum_{n=1}^{N} |h_{b,n}||h_{n,e}| \right)^2}{P_b \eta_d (b_h^H \Theta_{b,u})^2 + \sigma^2_r} < r_{th}^{\tau_c} \right]. \]

In the following theorem, we provide the analytical expression for the OP.

---

2To mitigate the effect of triple fading at R, UAV’s location can be optimized to maximize its SNR. However, this study is beyond the scope of the current work and is hence left for the future research.
Theorem 2. The OP of primary system with optimal phase shifts is given by

$$P_{\text{out},\text{pri}}(R_p) = \frac{L}{n=0} \exp \left( \frac{\sigma_n^2}{P_b N \Omega_{\text{out},x} \eta d_2} \right) \frac{2 \Gamma(k_x + n + 1)}{N \Omega_{\text{out},x} \eta d_2} \times A(R_p) \frac{1}{N \Omega_{\text{out},x} \eta d_2} d_1 \beta^2 e^{2} \times \mathcal{D}_{-(k_x + n + 2)} \left( \sqrt{\frac{2 \beta^2 e^{2} \eta d_2}{N \Omega_{\text{out},x}}} \right).$$

(13)

Proof. Please refer to Appendix [B].

To further obtain the insights into the derived OP expression, we obtain its asymptotic approximation at high transmit power, i.e., $P_b \to \infty$.

Corollary 1. The asymptotic OP of the primary system can be derived as

$$P_{\text{out},\text{pri}}(R_p) \approx \sum_{n=0}^{L} \left( \frac{2d_1 \beta^2 e^{2}}{r_{th} \eta d_2 N \Omega_{\text{out},x}} \right)^{k_x+n} \times (k_x + n + 1) \exp \left( \frac{r_{th} \eta d_2 N \Omega_{\text{out},x}}{8d_1 \beta^2 e^{2}} \right) \times \mathcal{D}_{-(k_x + n + 2)} \left( \sqrt{\frac{2 \beta^2 e^{2} \eta d_2}{N \Omega_{\text{out},x}}} \right).$$

(15)

Proof. See Appendix [C].

Remark: It can be noted from (15) in Corollary [1] that OP of the primary system at asymptotic limit is independent of the transmit power $P_b$. Such independence from the transmit power will lead to an error floor in the outage performance. This observation can also be validated via numerical results, as we shall observe later in Section VII.

2) Primary System with Random Phase Shifts

When perfect CSI is not available at S, the phase shifts of IRS can not be optimally co-phased viz., $\varphi_n = -\angle h_{b,n} h_{n,c}$. As a result, the UE will experience random phase shifts. As such, random phase shifting can avoid requisition of the global CSI and eventually reduce the system overhead. Random phase shifting may also be applicable for the scenarios when perfect CSI is not available due to various impairments. For this case, OP can be expressed as

$$P_{\text{out},\text{pri},\text{rp}}(R_p) = \Pr \left[ \frac{P_b \eta d_2 |h_{b,u}^H \Theta_{n,t,c}^H|^2 + \sigma_c^2}{P_b \eta d_2 |h_{b,u}^H \Theta_{n,t,c}|^2} \leq r_{th} \right].$$

(16)

The following theorem provides the closed-form expression for the OP.

Theorem 3. The OP of primary system with random phase shifts can be expressed by

$$P_{\text{out},\text{pri},\text{rp}}(R_p) = 1 - \frac{1}{N \Omega_{\text{out},x} \eta d_2} \exp \left( \frac{-r_{th} \sigma_c^2}{P_b d_1 N \Omega_{\text{out},x}} \right) \times \left( \frac{r_{th} \eta d_2}{d_1 N \Omega_{\text{out},x} \eta d_2} + \frac{1}{N \Omega_{\text{out},x}} \right)^{-1}.$$

(17)

Proof. Please refer to Appendix [D].

Further, at asymptotic limit, i.e., $P_b \to \infty$, $P_{\text{out},\text{pri},\text{rp}}(R_p)$ can be expressed as

$$P_{\text{out},\text{pri},\text{rp}}(R_p) \approx \frac{d_1 \Omega_{\text{out}}}{N \Omega_{\text{out},x} \eta d_2} + d_1 \Omega_{\text{out}}$$

(18)

where (18) can be derived by computing the integral in (17) for $P_b \to \infty$.

Remark: Similar to the case of optimal phase shifts, OP of primary system with random phase shifting is also independent of the transmit power $P_b$ at asymptotic limit which will give rise to an error floor. Moreover, it can also be noted that $P_{\text{out},\text{rp}}(R_p)$ in (18) does not depend on number of reflecting elements $N$. Consequently, the outage performance may remain unaffected with respect to $N$ at higher $P_b$. These inferences can also be verified using numerical results in Section V.

3) Backscattering Secondary System

For the backscattering secondary system, an outage occurs if either R is unable to successfully perform SIC or SNR $\Lambda_R^e$ at reader R falls below a specific threshold. Based on the SIC probability, the OP can be formulated as

$$P_{\text{out}}(R_s) = P_{\text{sic}}(\tau) + P_{\text{sic}}(\tau) \Pr [\log_2 (1 + \Lambda_R^e) \leq R_s],$$

(19)

where $P_{\text{sic}}(\tau)$ is as given in Theorem [1] with $P_{\text{sic}}(\tau) = 1 - P_{\text{sic}}(\tau)$. On substituting the SNR $\Lambda_R^e$ from [9], we re-write (19) as

$$P_{\text{out}}(R_s) = P_{\text{sic}}(\tau) + P_{\text{sic}}(\tau) \Pr \left[ \frac{P_b \eta d_3}{\sigma_r^2} |h_{b,u}^H \Theta_{n,t,c}|^2 \leq r_{th} \right],$$

(20)

where $R_s$ is a target rate and $r_{th}^s = 2^{R_s} - 1$. Following corollary provides the closed-form solution for the above equation.

Corollary 2. The OP of the backscattering secondary system can be expressed as

$$P_{\text{out}}(R_s) = P_{\text{sic}}(\tau) + P_{\text{sic}}(\tau) \times \sum_{k=0}^{\infty} (-1)^k \exp \left( \frac{-kr_{th}^s \sigma_r^2}{P_b \eta d_3 N \Omega_{\text{out},x}} \right),$$

(21)

Proof. Following the reasoning in Appendix [A] it can be established that the RV $Z = h_{b,u}^H \Theta_{n,t,c}$ can be statistically characterized using a complex Gaussian distribution. Consequently, $|Z|^2$ will follow an exponential distribution with the CDF given by

$$F_z(z) = 1 - \exp \left( -\frac{z}{N \Omega_{\text{out},x}} \right).$$

(22)
Using this CDF in \((21)\), we can obtain the desired expression in Corollary 2.

In the following corollary, we obtain asymptotic OP of the backscattering secondary system.

**Corollary 3.** At higher transmit power, i.e., \(P_b \to \infty\), the asymptotic OP of the backscattering secondary system can be expressed as

\[
P_{\text{out}}(R_s) \approx \frac{P_{\text{sec}}^{\text{asy}}(\tau) + P_{\text{sec}}^{\text{asy}}(\tau)}{P_b \eta d_3 N \Omega_{bu} \Omega_{ut}} - \frac{r_{th}^2}{P_b \eta d_3 N \Omega_{bu} \Omega_{ut}},
\]

where \(P_{\text{sec}}^{\text{asy}}(\tau) = 1 - P_{\text{sec}}^{\text{asy}}(\tau)\) and \(P_{\text{sec}}^{\text{asy}}(\tau)\) is given by

\[
P_{\text{sec}}^{\text{asy}}(\tau) = \frac{\bar{d}_4 \Omega_{ur}}{\Omega_{ut} + \bar{d}_4 \Omega_{ur}}.
\]

**Proof.** See Appendix E.

Dependence of \(P_{\text{out}}(R_s)\) on \(N\) at higher \(P_b\) signifies that the increase in the number of reflecting elements can enhance the OP performance of secondary. However, the product of \(P_b\) and \(N\) at their higher values leads to negligible second term in \((23)\). As a result, the OP would be predominantly govern by the term \(P_{\text{sec}}^{\text{asy}}(\tau)\) and thus, saturated with respect to \(P_b\) and \(N\) owing to the independence from them.

Next, we analyze the ESE of the proposed network configuration for both primary and backscattering secondary systems.

**B. Ergodic Spectral Efficiency**

In what follows under this subsection, we analyze another important performance metric called ESE for the legacy primary system as well as backscattering secondary system.

1) **Primary System with Optimal Phase Shifts**

Based on the SNR \(\Lambda_{\text{pri}}\) in (5), the ESE for the primary system can be expressed as

\[
C_{\text{pri}} = \mathbb{E} \left[ \log_2 \left( 1 + \frac{P_b \tilde{d}_1 |h_{b,u}^H \Theta_{h_{u,e}}|^2}{P_b \eta \tilde{d}_2 |h_{b,u}^H \Theta_{h_{u,t,e}}|^2 + \sigma_e^2} \right) \right].
\]

For the optimal phase shifts at IRS, \((25)\) can be re-expressed as

\[
C_{\text{pri}} = \mathbb{E} \left[ \log_2 \left( 1 + \frac{P_b \tilde{d}_1 \left( \sum_{n=1}^{N} |h_{b,n}| |h_{n,e}| \right)^2}{P_b \eta \tilde{d}_2 |h_{b,u}^H \Theta_{h_{u,t,e}}|^2 + \sigma_e^2} \right) \right] = \mathbb{E} \left[ \log_2 \left( P_b \tilde{d}_1 |\tilde{X}|^2 + P_b \eta \tilde{d}_2 |W|^2 + \sigma_e^2 \right) \right] - \mathbb{E} \left[ \log_2 \left( P_b \eta \tilde{d}_2 |W|^2 + \sigma_e^2 \right) \right].
\]

where \(\tilde{X} = \sum_{n=1}^{N} |h_{b,n}| |h_{n,e}|\). It appears that obtaining the closed-form solution of the above expression is rather intricate. Therefore, we seek for its approximation by using the Jensen’s inequality as follows

\[
C_{\text{pri}} \approx \log_2 \left( P_b \tilde{d}_1 \mathbb{E} |\tilde{X}|^2 + P_b \eta \tilde{d}_2 \mathbb{E} |W|^2 + \sigma_e^2 \right) - \log_2 \left( P_b \eta \tilde{d}_2 \mathbb{E} |W|^2 + \sigma_e^2 \right),
\]

following the statistical characterization, as derived in Appendix F one can obtain

\[
\mathbb{E}[|\tilde{X}|^2] = k_e \beta^2 \left(1 + k_e \right)
\]

\[
\mathbb{E}[|W|^2] = N \Omega_{bu} \Omega_{ut}.\]

Finally, using these values in \((27)\), we can obtain a simplified approximation for the ESE of primary system with optimal phase shifts.

2) **Primary System with Random Phase Shifts**

The ESE for the primary system with random phase shifts at IRS can be given by

\[
C_{\text{pri, rep}} = \mathbb{E} \left[ \log_2 \left( 1 + \frac{P_b \tilde{d}_1 |h_{b,u}^H \Theta_{h_{u,e}}|^2}{P_b \eta \tilde{d}_2 |h_{b,u}^H \Theta_{h_{u,t,e}}|^2 + \sigma_e^2} \right) \right],
\]

which, on using the Jensen’s inequality, can be expressed as

\[
C_{\text{pri}} \approx \log_2 \left( P_b \tilde{d}_1 \mathbb{E} |\tilde{X}|^2 + P_b \eta \tilde{d}_2 \mathbb{E} |W|^2 + \sigma_e^2 \right) - \log_2 \left( P_b \eta \tilde{d}_2 \mathbb{E} |W|^2 + \sigma_e^2 \right).
\]

Based on \((22)\) in Appendix D we can deduce that \(\mathbb{E}[|\tilde{X}|^2] = N \Omega_{bu} \Omega_{ut}\). Using this along with \((29)\) and thereby substituting them into \((31)\), we can obtain the ESE of the primary system for the random phase shifts.

3) **Backscattering Secondary System**

Depending on the SNR \(\Lambda_{\text{sec}}\) in \((3)\), the ESE for the secondary system can be formulated as

\[
C_{\text{sec}} = P_{\text{sec}}(\tau) \mathbb{E} \left[ \log_2 \left( 1 + \frac{P_b \tilde{d}_1 |h_{b,u}^H \Theta_{h_{u,t,e}}|^2}{P_b \eta \tilde{d}_2 |h_{b,u}^H \Theta_{h_{u,t,e}}|^2 + \sigma_e^2} \right) \right].
\]

On evaluating the above expectation, the exact closed-form expression for the ESE of backscattering secondary system can be given by

\[
C_{\text{sec}} = - \log_2 (e) P_{\text{sec}}(\tau) \exp \left( \frac{-\sigma_e^2}{P_b \eta \tilde{d}_2 \Omega_{bu} \Omega_{ut}} \right) \times \mathbb{E}[|W|^2 + \sigma_e^2].
\]

The proof of the derivation of \((33)\) is presented in Appendix G.

Based on the analyses in this section, the forthcoming section presents several numerical and simulation results to validate the theoretical analysis and thereby discusses the impact of various design parameters to provide insights.

**V. NUMERICAL RESULTS AND DISCUSSION**

This section presents the numerical results based on the theoretical analysis. Extensive Monte Carlo simulations have been performed to validate the derived analytical results. We set the several system parameters as \(\Omega_{bu} = \Omega_{ut} = 2, \Omega_{se} = 3.5, \Omega_{ut,e} = 0.1, \Omega_{ut,w} = 0.5, m_{bu} = m_{ue} = 1, C = 20, B = 0.5, c_5 = -1.5, f_5 = 3.5\). Without losing generality, we consider \(H = 1.5\) km, \(r = 0.5\) km, \(R_p = 3, R_b = 0.1, d_0 = 0\) m, \(d_b = [-2 -2 0]^T\) km, \(q_b = [3 0 0]^T\) km, \(q_u = [3 -1 0]^T\) m, \(q_r = [5 -1 0]^T\) m, \(\alpha_0 = 2.5, \tau = 0.1, \sigma_e^2 = \sigma_r^2 = -10\) dBm, unless stated otherwise. It is also assumed that, for the
random phase shifts, the resulting phase errors are uniformly distributed between 0 and $2\pi$. For illustrating the numerical results, we use solid/dash-dot/dash-dash lines to represent the analytical results derived in Section IV while dotted lines for the asymptotic results.

In Fig. 2 we plot the outage performance of primary network in terms of the transmit power $P_b$ for the random phase shifts at IRS. Apparently, the analytical results are well-matched with the simulation results, which corroborate the theoretical analysis. Clearly, the asymptotic curves also follow the analytic curves at high $P_b$. It can be observed from the curves that, for the random phase shifts, increase in $N$ does not significantly enhance the OP performance. Evidently, random phase shifting is unable to utilize the available degrees of freedom effectively. Further, a small performance improvement with $N$ can be witnessed in low-to-medium $P_b$ regime, whereas, for the high $P_b$, performance almost remains unaffected with $N$. Moreover, the performance is observed to be saturated at high power regime which can be attributed to the interference from the backscattering transmission. The error floor at higher $P_b$ can also be witnessed from the flat asymptotic curves. Further, as backscattering efficiency $\eta$ increases, the performance deteriorates as higher $\eta$ engenders high interference to primary transmission.

In Fig. 3, we plot the outage performance of primary system with optimal phase shifts in terms of the transmit power $P_b$.}

![Fig. 2: OP of primary system with random phase shifts in terms of the transmit power $P_b$.](image)

![Fig. 3: OP of primary system with optimal phase shifts in terms of the transmit power $P_b$.](image)
Fig. 4: OP of backscattering secondary system in terms of the transmit power $P_b$.

Fig. 5: OP of primary and secondary systems in terms of the UAV’s location.

Fig. 6: ESE of primary system with optimal phase shifts in terms of the transmit power $P_b$.

Fig. 7: ESE of primary system with random phase shifts in terms of the transmit power $P_b$.

and Fig. 7, it is apparent that the gap between actual capacity (represented by simulation markers) and Jensen’s bound when compared with the gap between actual capacity and obtained approximation is significantly high. This suggests that the obtained approximation is closer to the actual results than the Jensen’s bound.

Fig. 8 illustrates the ESE performance of backscattering secondary system with respect to transmit power $P_b$. Hereby, it can be observed that increase in the number of reflective elements $N$ results in enhanced ESE performance. Further, on comparing the curves at lower and higher $P_b$, it can be concluded that the ESE performance improvement with respect to $N$ is higher at high transmit power. However, unlike the primary system, the ESE performance of secondary system does not saturate at higher $P_b$ and monotonically improves with respect to $P_b$. 

Fig. 8: ESE of backscattering secondary system in terms of the transmit power $P_b$.

VI. CONCLUSION

We examined a network configuration that enabled AmBC assisted co-existence of a secondary system in aerial-IRS wireless networks. The performance is characterized by analyzing the OP and ESE. Evidently, the deployment of an UAV-IRS offers additional degrees of freedom leading to the enhanced performance for the primary system with optimal phase shifts and also for the backscattering secondary system with respect to number of reflective elements $N$. Primary system with random phase shifting at IRS is unable to utilize the available degrees of freedom effectively and hence does not witness significant performance improvement with $N$. Also, it has been observed that backscatter efficiency is a crucial design parameter which can significantly affect the performance of both the systems. Further, it has also been noted that ESE can be improved by increasing the reflective elements of IRS. In essence, we demonstrated the feasibility of co-existence of secondary system in the primary’s spectrum using AmBC technology, which can offer both spectral- and energy-efficient solutions for the future networks’ deployment.

APPENDIX A

PROOF OF THEOREM 1

To evaluate the integral in (9), we first obtain the distribution of RV $Y = h_{b,u}^H \Theta h_{n,r}$. Due to random phase shifts at IRS, we can write $Y = \sum_{n=1}^{N} |h_{b,n}| |h_{n,r}| e^{i \theta_n}$ where $\theta_n = \varphi_n + \angle h_{b,n} h_{n,r}$. We express RV $Y$ as

$$ Y = \text{Re} \left\{ \sum_{n=1}^{N} |h_{b,n}| |h_{n,r}| e^{i \theta_n} \right\} + \text{Im} \left\{ \sum_{n=1}^{N} |h_{b,n}| |h_{n,r}| e^{i \theta_n} \right\} = Y^R_n + Y^I_n. \quad (A.1) $$

For large $N$, it has been shown that $Y^R_n$ and $Y^I_n$ for $n \neq m$, are independent [32], [38] and thus, by using central limit theorem, they can be represented using Gaussian distribution as

$$ Y^R_n, Y^I_n \sim \mathcal{N} \left( 0, \frac{N}{\Omega_{bu, ur}} \right). \quad (A.2) $$

Further, due to independence between the real and imaginary parts, RV $Y$ follows a complex Gaussian distribution. As a consequence, $|Y|$ can be characterized by a Rayleigh distribution. The accuracy of such characterization can be witnessed from the Fig. 9. As a consequence, $|Y|^2$ follows an exponential distribution [27] with PDF and CDF, respectively, as

$$ f_{|Y|^2}(y) = \frac{1}{N \Omega_{bu, ur}} \exp \left( - \frac{y}{N \Omega_{bu, ur}} \right) \quad (A.3) $$

and

$$ F_{|Y|^2}(y) = 1 - \exp \left( - \frac{y}{N \Omega_{bu, ur}} \right). \quad (A.4) $$

Following the similar lines of derivation, PDF of $|Z|^2$ can be given by

$$ f_{|Z|^2}(z) = \frac{1}{N \Omega_{bu, ut} \Omega_{ur}} \exp \left( - \frac{z}{N \Omega_{bu, ut} \Omega_{ur}} \right). \quad (A.5) $$

Next, substituting the obtained CDF $F_Y(y)$ and PDF $f_{|Z|^2}(z)$ into (9), we can write $P_{sic}(\tau)$ as

$$ P_{sic}(\tau) = \frac{1}{N \Omega_{bu, ut}} \int_{z=0}^{\infty} \exp \left( -\tau P_b d_3 (z + \sigma_e^2) \right) \times \exp \left( - \frac{z}{N \Omega_{bu, ut} \Omega_{ur}} \right) dz. \quad (A.6) $$

after solving the above integral, one can arrive at the expression in Theorem 2.
Appendix B
Proof of Theorem 2

From the definition of OP of the primary system in (12), we have
\[ P_{out}^{pri}(R_{p}) = \Pr \left( \frac{P_{b}d_{1}X^2}{P_{b}d_{2}|W|^{2}+\sigma^2} \leq r_{th}^{p} \right) \]
\[ = \int_{w=0}^{\infty} F_{X}(\sqrt{\frac{r_{th}^{p}(P_{b}d_{2}|w|^{2}+\sigma^2)}{P_{b}d_{1}}}) f_{|W|^{2}}(w) dw, \quad (B.1) \]
where \( X = \sum_{n=1}^{N} h_{b,n}h_{n,c} \). To evaluate the above integral, we first characterize the distribution of RV \( X \) using moment matching. As \( h_{b,n} \) and \( h_{n,c} \) follow Nakagami-\( m \) distribution, the PDF of their product \( \Xi_{n} = |h_{b,n}h_{n,c}| \) can be readily obtained as \([40]\)
\[ f_{\Xi_{n}}(x) = \frac{4}{\Gamma(m_{b})\Gamma(m_{c})} \left( \frac{m_{b}m_{c}}{\Omega_{b}\Omega_{c}} \right)^{\frac{m_{b}+m_{c}}{2}} x^{m_{b}+m_{c}-1} K_{m_{b}-m_{c}} \left( 2x \sqrt{\frac{m_{b}m_{c}}{\Omega_{b}\Omega_{c}}} \right). \quad (B.2) \]
Next, we obtain the \( r \)-th moment \( E[\Xi_{n}(r)] \) of the RV \( \Xi_{n} \) as
\[ E[\Xi_{n}(r)] = \int_{x=0}^{\infty} x^{r} f_{\Xi_{n}}(x) dx, \quad (B.3) \]
on substituting PDF \( f_{\Xi_{n}}(x) \) from (B.2) into (B.3) and thereafter solving the resultant integral using \([29] \) eq. (6.561.16)], one can obtain
\[ E[\Xi_{n}(r)] = \left( \frac{\Omega_{b}\Omega_{c}}{m_{b}m_{c}} \right)^{\frac{r}{2}} \frac{\Gamma(m_{b}+\frac{r}{2})}{\Gamma(m_{b})} \frac{\Gamma(m_{c}+\frac{r}{2})}{\Gamma(m_{c})}, \quad (B.4) \]
Based on the above, we can obtain mean and variance as
\[ E[\Xi_{n}] = E[\Xi_{n}(1)] = \left( \frac{\Omega_{b}\Omega_{c}}{m_{b}m_{c}} \right)^{\frac{1}{2}} \frac{\Gamma(m_{b}+\frac{1}{2})}{\Gamma(m_{b})} \frac{\Gamma(m_{c}+\frac{1}{2})}{\Gamma(m_{c})}, \quad (B.5) \]
and \( \text{Var}[\Xi_{n}] = E[\Xi_{n}(2)] - (E[\Xi_{n}])^{2} = \Omega_{b}\Omega_{c} - \left( E[\Xi_{n}] \right)^{2}. \quad (B.6) \]
Finally, we can match the distribution of \( \tilde{X} = \sum_{n=1}^{N} \Xi_{n} \) to a Gamma distribution with the following shape \( k_{x} \) and scale \( \beta_{x} \) parameters
\[ k_{x} = N \frac{E[\Xi_{n}]^{2}}{\text{Var}[\Xi_{n}]}, \quad \beta_{x} = \frac{\text{Var}[\Xi_{n}]}{E[\Xi_{n}].} \quad (B.7) \]
The accuracy of this characterization can be witnessed from the Fig. 10. Next, using the obtained parameters in (B.7), the CDF of a Gamma distributed RV \( \tilde{X} \) can be given by \([41]\)
\[ F_{\tilde{X}}(x) = \frac{1}{\Gamma(k_{x})} \left( \frac{x}{\beta_{x}} \right)^{k_{x}} \right) \frac{\Gamma(k_{x}+n+1)}{\Gamma(k_{x})}, \quad (B.8) \]
which can be expressed using a series representation of incomplete Gamma function \([42]\)
\[ F_{\tilde{X}}(x) = \sum_{n=0}^{L} \frac{1}{\Gamma(k_{x}+n+1)\beta_{x}^{k_{x}+n+1}} x^{k_{x}+n} \exp \left( -\frac{x}{\beta_{x}} \right). \quad (B.9) \]
Hereby, \( r \) equals infinity provides exact values of \( F_{\tilde{X}}(x) \), however, even for \( r = 20 \), the series converges to sufficient level of accuracy. Further, following the approach in Appendix A, we obtain PDF of \( |W|^{2} \) as
\[ f_{|W|^{2}}(w) = \frac{1}{N\Omega_{b}\Omega_{c}} \exp \left( -\frac{w}{N\Omega_{b}\Omega_{c}} \right). \quad (B.10) \]
On substituting (B.2) and (B.10) in (B.1) and followed by appropriate substitutions, we have
\[ P_{out}^{pri}(R_{p}) = \sum_{n=0}^{L} \exp \left( -\frac{\sigma_{e}^{2}}{P_{b}N\Omega_{b}\Omega_{c}} \right) \frac{2}{\Gamma(k_{x}+n+1)} \times \frac{1}{N\Omega_{b}\Omega_{c}} \frac{d_{1}^{2}}{r_{th}^{2}\eta^{2}d_{2}} N\Omega_{b}\Omega_{c} \frac{k_{x}+n+1}{2} \times \exp \left( -v - \frac{d_{1}^{2}v^{2}}{r_{th}^{2}\eta^{2}d_{2}N\Omega_{b}\Omega_{c}} \right) dv. \quad (B.11) \]
For simplification, let us denote the integral in (B.11) by \( \mathcal{A}(R_{p}) \). Apparently, the integral \( \mathcal{A}(R_{p}) \) is intricate to evaluate for the closed-form solution, however, it can be analyzed using the numerical methods or any computing software.

Appendix C
Proof of Corollary 1

Using (12) and (B.1), we can express \( P_{out}^{pri}(R_{p}) \) at asymptotic limit \( P_{b} \to \infty \) as
\[ P_{out}^{pri}(R_{p}) \sim \int_{w=0}^{\infty} F_{X}(\sqrt{\frac{r_{th}^{p}\eta^{2}d_{2}}{d_{1}}}) f_{|W|^{2}}(w) dw, \quad (C.1) \]
on invoking CDF $F_X(\cdot)$ from (B.9) and PDF $f_W(w)$ from (B.10) into (C.1) followed by variable transformation and substitution, we can express

$$P_{out}(R_p) \approx \sum_{n=0}^{L} \frac{2}{\Gamma(k_x+n+1)} \frac{d_1 \beta_x^2}{\eta_d^2 \Omega_{nu} \Omega_{ut}} \int_{t=0}^{\infty} k_x+n+1 \exp \left( -t - \frac{\beta_x^2 d_1 t^2}{\Gamma(k_x+n+1) \eta_d^2 \Omega_{nu} \Omega_{ut}} \right) dt, \quad (C.2)$$

on solving the above integral using [29] eq. (3.462), we can obtain the expression as given in Corollary [1].

**APPENDIX D**

**Proof of Theorem [3]**

To derive the OP of primary system with random phase shifts, we can express (17) in an integral form as

$$P_{out,r}(R_p) = \int_{w=0}^{\infty} F_{|X|^2} \left( \frac{p_{th}}{P_t d_1} (P_b \eta_d d_2 w + \sigma_n^2) \right) f_{|W|^2}(w) dw. \quad (D.1)$$

Owing to random phase shifts at IRS, the RV $X$ can be written as $X = h_{b,n}^H \Theta_{h,n} e^{j \theta_n} = \sum_{n=1}^{N} h_{b,n} |h_{n,e}| e^{j \theta_n}$, where $	heta_n = \varphi_n + \angle[h_{b,n},h_{n,e}]$. Following the reasoning in Appendix A it can be shown that the amplitude of complex RV $X$ can be characterized by a Rayleigh distribution and thereby $|X|^2$ follows an exponential distribution with its PDF and CDF given, respectively, by

$$f_{|X|^2}(x) = \frac{1}{N \Omega_{nu} \Omega_{ue}} \exp \left( -\frac{x}{N \Omega_{nu} \Omega_{ue}} \right), \quad (D.2)$$

$$F_{|X|^2}(x) = 1 - \exp \left( -\frac{x}{N \Omega_{nu} \Omega_{ue}} \right). \quad (D.3)$$

On invoking $F_{|X|^2}(x)$ from (D.3) and $f_{|W|^2}(w)$ from (B.10) into (D.1) and subsequently evaluating the resultant integral leads to expression of $P_{out,r}(R_p)$ in Theorem [3].

**APPENDIX E**

**Proof of Corollary [3]**

To derive OP in Corollary [3] we first obtain $P_{sic}^{asy}(\tau)$ using (9) at $P_b \rightarrow \infty$ as

$$P_{sic}^{asy}(\tau) \approx 1 - \int_{z=0}^{\infty} F_{|Y|^2} \left( \frac{\tau \eta_d d_2}{d_4} \right) f_{|Z|^2}(z) dz, \quad (E.1)$$

which, after substituting the respective CDF and PDF, can be expressed as

$$P_{sic}^{asy}(\tau) \approx \frac{1}{N \Omega_{nu} \Omega_{ue}} \int_{z=0}^{\infty} \exp \left( -\frac{\tau \eta_d d_2 z}{d_4 N \Omega_{nu} \Omega_{ue}} \right) \left( -\frac{z}{N \Omega_{nu} \Omega_{ue}} \right) dz, \quad (E.2)$$

on computing the above integral, (24) can be obtained. Further, utilizing the approximation $\exp(-x) \approx 1 - x$, along with obtained $P_{sic}^{asy}(\tau)$ into (23), Corollary [3] is proved.

**APPENDIX F**

**Derivation of (28) and (29)**

To derive $E[|\tilde{X}|^2]$, we use the transformation on a RV $V = |\tilde{X}|^2$ as follows

$$f_{|\tilde{X}|^2}(x) = F_{\tilde{X}}(\sqrt{x}), \quad x > 0, \quad (F.1)$$

based on the above relationship, the PDF of $|\tilde{X}|^2$ can be expressed as

$$f_{|\tilde{X}|^2}(x) = f_V(x) = \frac{1}{2 \sqrt{x}} f_{\tilde{X}}(\sqrt{x}). \quad (F.2)$$

Utilizing this PDF, we can further obtain $E[|\tilde{X}|^2]$ as

$$E[|\tilde{X}|^2] = \int_{0}^{\infty} f_V(v) dv = \int_{0}^{\infty} \frac{\sqrt{v}}{2} f_{\tilde{X}}(\sqrt{v}) dv. \quad (F.3)$$

From Appendix F we can deduce

$$f_{\tilde{X}}(x) = \frac{1}{\Gamma(k_x) \beta_x^2} x^{k_x-1} \exp \left( -\frac{x}{\beta_x} \right), \quad (F.4)$$

on invoking (F.4) into (F.3) followed by subsequent evaluation of the resultant integral yields (28). Further, in Appendix F it is observed that $|W|^2$ can be characterized by an exponential distribution with its PDF in (B.10). Therefore, $E[|W|^2]$ can be readily obtained as given by (29).

**APPENDIX G**

**Derivation of (33)**

To derive (33), we first use the following transformation

$$E[\log_2 (1 + \zeta)] = \log_2(e) \int_{0}^{\infty} \frac{1 - F_{\zeta}(z)}{1 + z} dz, \quad (G.1)$$

where $\zeta = \frac{P_{b}}{\sigma_n^2} \eta_d d_3 [h_{b,n}^H \Theta_{h,n}]^2 = \frac{P_{b}}{\sigma_n^2} \eta_d^2 d_3 Z^2$ and $F_{\zeta}(\cdot)$ is its CDF. Based on [A.3] in Appendix A we can obtain CDF of $\zeta$ as

$$F_{\zeta}(z) = 1 - \exp \left( \frac{-z \sigma_n^2}{P_{b} \eta_d d_3 N \Omega_{nu} \Omega_{ut}} \right). \quad (G.2)$$

Invoking (G.1) and (G.2) in (32) and eventually computing the resultant integral with the aid of (29) eq. (3.352.4), the expression in (33) can be obtained.

Sumit Gautam (Member, IEEE) received the B.Tech. degree (Hons.) in electronics and communication engineering from the LNM Institute of Information Technology (Deemed University), Jaipur, India, in 2013, the M.S. degree in electronics and communication engineering by research from the International Institute of Information Technology Hyderabad (Deemed University), Hyderabad, India, in 2017, and the Ph.D. degree in computer science (with focus on wireless communications) from the Interdisciplinary Centre for Security, Reliability, and Trust (SnT), University of Luxembourg, Luxembourg, in 2020. Since December 2021, he is working as an Assistant Professor at the Indian Institute of Technology - Indore, India. Prior to this, he worked as a Consultant: BTS Algorithm and Channel Modeling Expert at Incluso AB (Client: Huawei Technologies Sweden AB), in Gothenburg, Sweden, between August 2021 and December 2021. He was a Research Associate/Postdoctoral Researcher at the SnT, University of Luxembourg from March 2020 to July 2021. His research interests include simultaneous wireless information and power transfer, caching, optimization methods, hybrid active-and-passive cooperative communications, and precoding for multi-group multicast systems.

Shree Krishna Sharma (Senior Member, IEEE) Shree Krishna Sharma obtained his PhD degree in wireless communications from University of Luxembourg in 2014. He held various research and academic positions at the SnT, University of Luxembourg; Western University, Canada; and Ryerson University, Canada. He has published more than 100 technical papers in scholarly journals, international conferences, and book chapters, and has over 4400 google scholar citations with an h-index of 30. He is a Senior Member of IEEE and a lead editor of two IET books on “Satellite Communications in the 5G Era” and “Communications Technologies for Networked Smart Cities”.

Symeon Chatzinotas (Senior Member, IEEE) is currently Full Professor and Head of the SIGCOM Research Group at SnT, University of Luxembourg. He coordinates research activities in communications and networking, acting as a PI in over 40 projects and is the main representative for 3GPP, ETSI, DVB. In the past, he worked as a Visiting Professor at the University of Parma, Italy, lecturing on 5G Wireless Networks. He was involved in numerous R&D projects for NCSR Demokritos, CERTH Hellas and CCSR, University of Surrey. He was co-recipient of the 2014 IEEE Distinguished Contributions to Satellite Communications Award and Best Paper Awards at 5GWF, EURASIP JWCN, CROWNCOM, ICSSC. He has (co-)authored more than 600 technical papers in refereed international journals, conferences and scientific books. He is currently on the editorial board of the IEEE Transactions on Communications, IEEE Open Journal of Vehicular Technology, and the International Journal of Satellite Communications and Networking.
