Crystals from categorified quantum groups

Aaron D. Lauda and Monica Vazirani

September 10, 2009

Abstract

We study the crystal structure on categories of graded modules over algebras which
categorify the negative half of the quantum Kac-Moody algebra associated to a symmetrizable
Cartan data. We identify this crystal with Kashiwara’s crystal for the corresponding
negative half of the quantum Kac-Moody algebra. As a consequence, we show the simple
graded modules for certain cyclotomic quotients carry the structure of highest weight
crystals, and hence compute the rank of the corresponding Grothendieck group.

1 Introduction

In [KL09, KL08a] a family $R$ of graded algebras was introduced that categorifies the integral form $\mathcal{A}U_q := \mathcal{A}U_q(g)$ of the negative half of the quantum enveloping algebra $U_q(g)$ associated to a symmetrizable Kac-Moody algebra $g$. The grading on these algebras equips the Grothendieck group $K_0(R_{-\text{pmod}})$ of the category of finitely-generated graded projective $R$-modules with the structure of a $\mathbb{C}[q, q^{-1}]$-module, where $q^r[M] := [M \{r\}]$, and $M \{r\}$ denotes a graded module $M$ with its grading shifted up by $r$. Natural parabolic induction and restriction functors give $K_0(R_{-\text{pmod}})$ the structure of a (twisted) $\mathbb{C}[q, q^{-1}]$-bialgebra.

In [KL09, KL08a] an explicit isomorphism of twisted bialgebras was given between $\mathcal{A}U_q$ and $K_0(R_{-\text{pmod}})$. Several conjectures were also made in [KL09, KL08a]. One conjecture that remains unsolved is the so called cyclotomic quotient conjecture which suggests a close connection between certain finite dimensional quotients of the algebras $R$ and the integrable representation theory of quantum Kac-Moody algebras. While this conjecture has been proven in finite and affine type $A$ by Brundan and Kleshchev [BK09], very little is known in the case of an arbitrary symmetrizable Cartan datum. Here we show that simple graded modules for these cyclotomic quotients carry the structure of highest weight crystals. Hence we identify the rank of the corresponding Grothendieck group with the rank of the integral highest weight representation, thereby laying to rest a major component of the cyclotomic conjecture.

To explain these results more precisely, suppose we are given a symmetrizable Cartan datum where $I$ is the index set of simple roots. The algebras $R$ have a diagrammatic description and are determined by the symmetrizable Cartan datum of $g$ together with some extra parameters. In the literature these algebras have been called Khovanov-Lauda algebras, Khovanov-Lauda-Rouquier algebras, quiver Hecke algebras, and quiver nilHecke algebras.

For each $\nu \in \mathbb{N}[I]$ the block $R(\nu)$ of the algebra $R$ admits a finite dimensional quotient $R^\Lambda(\nu)$ associated to a highest weight $\Lambda$, called a cyclotomic quotient. These quotients were conjectured in [KL09, KL08a] to categorify the $\nu$-weight space of the integral version of the irreducible representation $V(\Lambda)$ of highest weight $\Lambda$ for $U_q(g)$, in the sense that there should be an isomorphism

$$V(\Lambda)_C \cong \bigoplus_{\nu \in \mathbb{N}[I]} K_0(R^\Lambda(\nu)_{-\text{pmod}})_C,$$

where $K_0(R^\Lambda(\nu)_{-\text{pmod}})_C$ denotes the complexified Grothendieck group of the category of graded finitely generated projective $R^\Lambda(\nu)$-modules. A special case of this conjecture was
proven in type $A$ by Brundan and Stroppel [BS08]. The more general conjecture was proven in finite and affine type $A$ by Brundan and Kleshchev [BK08, BK09]. They constructed an isomorphism

$$R^\Lambda(\nu) \cong H^\Lambda_\nu,$$

where $H^\Lambda_\nu$ is a block of the cyclotomic affine Hecke algebra $H^\Lambda_m$ as defined in [AK94, BM93, Che87]. This isomorphism induces a new grading on blocks of the cyclotomic affine Hecke algebra. This has led to the definition of graded Specht modules for cyclotomic Hecke algebras [BKW09], the construction of a homogeneous cellular basis for the cyclotomic quotients $R^\Lambda(\nu)$ in type $A$ [HM09], the introduction of gradings in the study of $q$-Schur algebras [Ari09], and an extension of the generalized LLT conjecture to the graded setting [BK09].

Ariki’s categorification theorem gave a geometric proof that the sum of complexified Grothendieck groups of cyclotomic Hecke algebras $H^\Lambda_m$ at an $N$th root of unity over $\mathbb{C}$, taken over all $m \geq 0$, was isomorphic to the highest weight representation $V(\Lambda)$ of $U(\hat{\mathfrak{sl}}_N)$ [Ari96], see [Ari99, Ari02, AM00, Mat99] and also [Gro94, LLT96]. Grojnowski gave a purely algebraic proof of this result, parameterizing the simple $H^\Lambda_m$-modules in terms of crystal data of highest weight crystals [Gro99].

Brundan and Kleshchev’s proof of the cyclotomic quotient conjecture in type $A$ utilized the isomorphism between the graded algebras $R^\Lambda(\nu)$ and blocks of the cyclotomic affine Hecke algebra, allowing them to extend Grojnowski’s crystal theoretic classification of simples of the ungraded affine Hecke algebra to the graded setting. By keeping careful track of the gradings, Brundan and Kleshchev were able to extend Ariki’s theorem to the graded setting, thereby proving the cyclotomic quotient conjecture in type $A$, as well as identifying the indecomposable projective modules for $R^\Lambda_\nu$ with the Kashiwara-Lusztig canonical basis for $V(\Lambda)$. Indeed, the algebras $R^\Lambda(\nu)$ were originally called cyclotomic quotients in [KL09] because they were expected to be graded extensions of the cyclotomic Hecke algebras for all types.

The study of cyclotomic quotients outside of type $A$ has been hindered by the lack of explicit bases for the algebras $R^\Lambda(\nu)$. Some explicit calculations of cyclotomic quotients $R^\Lambda(\nu)$ were made for level one and two representations [RTG], but it is not clear how to extend these results to all representations. The algebras $R(\nu)$ have a PBW basis that aid in computations. No such basis is known for the algebras $R^\Lambda(\nu)$.

In the symmetric case the algebras $R$ are related to Lusztig’s geometric categorification using perverse sheaves. Following Ringel [Rin90], Lusztig gave a geometric interpretation of $U_q = U_q(\mathfrak{g})$ [Lus90a, Lus90b, Lus91], see also [Lus93, Lus98]. This gave rise to a canonical basis for $U_q^-$. Kashiwara defined a crystal basis of $U_q^-$ for certain simple Lie algebras [Kas90b] and later proved its existence for all symmetrizable Kac-Moody algebras [Kas91, Kas90a]; the affine type $A$ case was proven by Misra and Miwa [MM90]. Kashiwara also constructed the so-called global crystal basis of $U_q^-$ [Kas91, Kas93, Kas90a]. Grojnowski and Lusztig [GL93] proved that the global crystal basis and the canonical basis are the same. The Kashiwara-Lusztig canonical basis of $U_q^-$ is a basis with remarkable positivity and integrality properties, and gives rise to bases in all irreducible integrable $U_q(\mathfrak{g})$-representations.

Varagnolo and Vasserot constructed an isomorphism between Ext-algebras of simple perverse sheaves on Lusztig quiver varieties [VV09] and the algebras $R(\nu)$ is the symmetric case, proving a conjecture from [KL09]. Consequently, one can identify indecomposable projectives for the algebras $R$ with simple perverse sheaves on Lusztig quiver varieties and the
Kashiwara-Lusztig canonical basis for $\mathcal{A}U_q^-$. Rouquier has also announced a similar result.

One should be able to deduce a classification of graded simple modules for the algebras $R^\Lambda(\nu)$ in the symmetric case using results of [KL09] and [VV09] together with Kashiwara and Saito’s geometric construction of crystals [KS97], but the details of this argument have not appeared. We expect that cyclotomic quotients $R^\Lambda(\nu)$ should also have a geometric interpretation in terms of Nakajima quiver varieties [Nak94].

In this paper we determine the size of the Grothendieck group for arbitrary cyclotomic quotients $R^\Lambda(\nu)$ associated to a symmetrizable Cartan datum. Rather than working geometrically, our methods are based strongly on the algebraic treatment of the affine Hecke algebra and its cyclotomic quotients introduced by Grojnowski [Gro99]. This approach extended Kleshchev’s results for the symmetric groups [Kle95, Kle96, Kle97], and utilizes earlier results of Vazirani [Vaz99, Vaz02] and Grojnowski-Vazirani [GV01]. Kleshchev’s book contains an excellent exposition of Grojnowski’s approach in the context of degenerate affine Hecke algebras [Kle05]. The idea is to introduce a crystal structure on categories of modules, interpreting Kashiwara operators module theoretically. To apply this approach to the study of algebras $R(\nu)$, rather than working with projective modules, we work over an algebraically closed field and utilize a $\mathbb{C}I[q,q^{-1}]$-bilinear pairing

$$(\mathcal{K}_0(R(\nu)\otimes\text{pmod}) \times \mathcal{G}_0(R(\nu)\otimes\text{fmod}) \rightarrow \mathbb{Z}[q,q^{-1}],$$

where $\mathcal{G}_0(R(\nu)\otimes\text{fmod})$ denotes the Grothendieck group of the category of finite dimensional graded $R(\nu)$-modules. This allows us to focus our attention on the graded simple modules for $R(\nu)$ and its cyclotomic quotients $R^\Lambda(\nu)$, rather than the indecomposable projective modules.

We study the crystal graph structure whose nodes are the graded simple $R(\nu)$ modules (up to grading shift) taken over all $\nu \in \mathbb{N}[\mathcal{I}]$. By identifying this crystal graph with the Kashiwara crystal $B(\infty)$ associated to $U_q^-$ we are able to define a crystal structure on the set of graded simple modules for the cyclotomic quotients $R^\Lambda(\nu)$ and show that it is the crystal graph $B(\Lambda)$. This allows us to view cyclotomic quotients of the algebras $R(\nu)$ as a categorification of the integrable highest weight representation $V(\Lambda)$ of $U_q^-$, proving part of the cyclotomic quotient conjecture from [KL09] in the general setting. This does not prove the entire cyclotomic quotient conjecture as our isomorphism is only an isomorphism of $U_q^-$-modules, not of $U_q(g)$-modules. Furthermore, one would also like to see an identification of the simple $R^\Lambda(\nu)$-modules with the dual basis of the Kashiwara-Lusztig canonical basis, or dual canonical basis, for $V(\Lambda)$.

All of the results in this paper should extend to Rouquier’s version of algebras $R(\nu)$ associated to Hermitian matrices, at least for those Hermitian matrices leading to graded algebras. We also believe that these results will fit naturally within Khovanov and Lauda’s framework of categorified quantum groups [Lau05, KL05], as well as Rouquier’s 2-representations of 2-Kac-Moody algebras [CR08, Rou08].

We have recently received a preprint from Kleshchev and Ram [KR09] where they describe all irreducible representations of algebras $R(\nu)$ in finite type from Lyndon words. Their work generalizes the fundamental work of [BZ77, Zel80] who parameterized and constructed the simple modules for the affine Hecke algebra in type $A$ with generic parameter in terms of $U^-(gl_{\infty})$.

We end the introduction with a brief outline of the article, highlighting other results to be found herein. In Section 1.1 we review the definition and key properties of the algebras
R(ν). In Section 2 we study various functors defined on the categories of graded modules over the algebras R(ν). In particular, Section 2.3 introduces the co-induction functor and proves several key results. In Section 3 we look at the morphisms induced by these functors on the Grothendieck rings.

Section 4 contains a brief review of crystal theory. Of key importance is the result of Kashiwara and Saito [KS97], recalled in Section 4.2 characterizing the crystal B(∞). In Section 5 we introduce crystal structures on the category of modules over algebras R(ν) and their cyclotomic quotients R_Λ(ν). After a detailed study of this crystal data in Section 6, these crystals are identified as the crystals B(∞) and B(Λ) in Section 7.

Acknowledgments: We thank Ian Grojnowski for suggesting this project and for many helpful discussions. We also thank Mikhail Khovanov for helpful discussions and comments. The first author was partially supported by the NSF grant DMS-0739392 and DMS-0855713. The second author was partially supported by the NSA grant #H982300910076, and would like to acknowledge Columbia’s RTG grant DMS-0739392 for supporting her visits to Columbia.

1.1 The algebras R(ν)

1.1.1 Cartan datum

Assume we are given a Cartan data

\[ P \rightarrow \mathbb{Z} \text{-module (called the weight lattice)} \]

\[ I \rightarrow \text{an index set for simple roots} \]

\[ \alpha_i \in P \text{ for } i \in I \text{ called simple roots} \]

\[ h_i \in P^\vee = \text{Hom}_\mathbb{Z}(P, \mathbb{Z}) \text{ called simple coroots} \]

\[ (\cdot, \cdot): P \times P \rightarrow \mathbb{Z} \text{ a bilinear form} \]

where we write \( (\cdot, \cdot): P^\vee \times P \rightarrow \mathbb{Z} \) for the canonical pairing. This data is required to satisfy the following axioms

\[
(\alpha_i, \alpha_i) \in 2\mathbb{Z}_{>0} \text{ for any } i \in I \tag{1.2}
\]

\[
\langle h_i, \lambda \rangle = 2\frac{(\alpha_i, \lambda)}{(\alpha_i, \alpha_i)} \text{ for } i \in I \text{ and } \lambda \in P \tag{1.3}
\]

\[
(\alpha_i, \alpha_j) \leq 0 \text{ for } i, j \in I \text{ with } i \neq j. \tag{1.4}
\]

Hence \( \{\langle h_i, \alpha_j \rangle\}_{i,j \in I} \) is a symmetrizable generalized Cartan matrix. In what follows we write

\[
a_{ij} = -\langle i, j \rangle := -\langle h_i, \alpha_j \rangle \tag{1.5}
\]

for \( i, j \in I \).

Let \( \Lambda_i \in P^+ \) be the fundamental weights defined by \( \langle h_j, \Lambda_i \rangle = \delta_{ij} \).

1.1.2 The algebra \( U_q^- \)

Associated to a Cartan datum one can define an algebra \( U_q^- \), the quantum deformation of the universal enveloping algebra of the “lower-triangular” subalgebra of a symmetrizable Kac-Moody algebra \( \mathfrak{g} \). Our discussion here follows Lusztig [Lus93].
Let \( q_i = q^{(\alpha_i, \alpha_i)} \), \([a]_i = q_i^{a-1} + q_i^{a-3} + \cdots + q_i^{1-a} \), \([a]_i! = [a]_i[a-1]_i \cdots [1]_i \). Denote by \( \mathcal{F} \) the free associative algebra over \( \mathbb{Q}(q) \) with generators \( \theta_i, i \in I \), and introduce q-divided powers \( \theta_i^{(a)} = \theta_i^a/[a]_i! \). The algebra \( \mathcal{F} \) is \( \mathbb{N}[I] \)-graded, with \( \theta_i \) in degree \( i \). The tensor square \( \mathcal{F} \otimes \mathcal{F} \) is an associative algebra with twisted multiplication

\[
(x_1 \otimes x_2)(x'_1 \otimes x'_2) = q^{-|x_2|-|x_1|} x_1 x'_1 \otimes x_2 x'_2
\]

for homogeneous \( x_1, x_2, x'_1, x'_2 \). The assignment \( r(\theta_i) = \theta_i \otimes 1 + 1 \otimes \theta_i \) extends to a unique algebra homomorphism \( r : \mathcal{F} \longrightarrow \mathcal{F} \otimes \mathcal{F} \).

Algebra \( \mathcal{F} \) carries a \( \mathbb{Q}(q) \)-bilinear form determined by the conditions

\begin{itemize}
    \item \((1,1) = 1\),
    \item \((\theta_i, \theta_j) = \delta_{i,j}(1-q_i^2)^{-1} \) for \( i, j \in I \),
    \item \((x, yy') = (r(x), y \otimes y') \) for \( x, y, y' \in \mathcal{F} \),
    \item \((xx', y) = (x \otimes x', r(y)) \) for \( x, x', y \in \mathcal{F} \).
\end{itemize}

The bilinear form \((,\)\) is symmetric. Its radical \( \mathcal{J} \) is a two-sided ideal of \( \mathcal{F} \). The form \((,\)\) descends to a nondegenerate form on the associative \( \mathbb{Q}(q) \)-algebra \( \mathcal{F} = \mathcal{F}/\mathcal{J} \).

**Theorem 1.1.** The ideal \( \mathcal{J} \) is generated by the elements

\[
\sum_{r+s=a_{ij}+1} (-1)^r \theta_i^{(r)} \theta_j \theta_i^{(s)}
\]

over all \( i, j \in I \), \( i \neq j \).

For a general Cartan datum, the only known proof of this theorem requires Lusztig’s geometric realization of \( \mathcal{F} \) via perverse sheaves. This proof is given in his book [Lus93, Theorem 33.1.3]. Less sophisticated proofs exist when the Cartan datum is finite.

**Remark 1.2.** Theorem 1.1 implies that \( \mathcal{F} \) is the quotient of \( \mathcal{F} \) by the quantum Serre relations

\[
\sum_{r+s=a_{ij}+1} (-1)^r \theta_i^{(r)} \theta_j \theta_i^{(s)} = 0.
\] (1.6)

Furthermore, since \( \mathcal{F} \) is a quotient of a free algebra, it also implies that there are no smaller relations in \( \mathcal{F} \). In particular, (1.6) can never hold for \( r + s = c + 1 \) with \( c < a_{ij} \).

Let \( U_q(\mathfrak{g}) \) denote the quantum enveloping algebra of a symmetrizable Kac-Moody algebra \( \mathfrak{g} \). There is a pair of injective algebra homomorphisms \( \mathcal{F} \rightarrow U_q(\mathfrak{g}) \), which sends \( \theta_i \mapsto e_i \), respectively \( \theta_i \mapsto f_i \). We denote the images of these homomorphisms as \( U_q^+(\mathfrak{g}) \) and \( U_q^-(\mathfrak{g}) \). Let \( \mathcal{A} = \mathbb{Z}[q, q^{-1}] \). The integral form of the algebra \( \mathcal{F} \), denoted \( \mathcal{A} \mathcal{F} \), is the \( \mathbb{Z}[q, q^{-1}] \)-subalgebra of \( \mathcal{F} \) generated by the divided powers \( \theta_i^{(a)} \), over all \( i \in I \) and \( a \in \mathbb{N} \). We write \( \mathcal{A} U_q^- \) for the corresponding integral form of the negative half of the quantum enveloping algebra \( U_q(\mathfrak{g}) \). The algebra \( \mathcal{A} \mathcal{F} \) admits a decomposition into weight spaces \( \mathcal{A} \mathcal{F} = \bigoplus_{\nu \in \mathbb{N}[I]} \mathcal{A} \mathcal{F}(\nu) \).

In the next section we introduce graded algebras \( R(\nu) \) whose Grothendieck ring was shown by Khovanov and Lauda to be isomorphic to \( \mathcal{A} \mathcal{F} \).
1.1.3 The definition of the algebra \( R(\nu) \)

Recall the definition from \[ \text{[KL09, KL08a]} \] of the algebra \( R \) associated to a Cartan datum. Let \( k \) be an algebraically closed field (of arbitrary characteristic). The algebra \( R \) is defined by finite \( k \)-linear combinations of braid–like diagrams in the plane, where each strand is coloured by a vertex \( i \in I \). Strands can intersect and can carry dots; however, triple intersections are not allowed. Diagrams are considered up to planar isotopy that do not change the combinatorial type of the diagram. We recall the local relations

\[
\begin{align*}
\cdots &= \begin{cases} 
0 & \text{if } i = j, \\
\alpha_{ij} - \alpha_{ji} & \text{if } (\alpha_i, \alpha_j) \neq 0.
\end{cases} \\
(1.7) &
\end{align*}
\]

\[
\begin{align*}
\begin{array}{c}
\bigcirc \\
in
\end{array} = 
\begin{array}{c}
\bigcirc \\
nonumber j
\end{array} 
\end{align*}
\]

\[
\begin{align*}
\begin{array}{c}
\bigcirc \\
in
\end{array} - 
\begin{array}{c}
\bigcirc \\
nonumber j
\end{array} = 
\begin{array}{c}
\bigcirc \\
in
\end{array} - 
\begin{array}{c}
\bigcirc \\
nonumber j
\end{array}
\end{align*}
\]

\[
\begin{align*}
\begin{array}{c}
\bigcirc \\
in
\end{array} - 
\begin{array}{c}
\bigcirc \\
nonumber j
\end{array} = 
\begin{array}{c}
\bigcirc \\
in
\end{array} - 
\begin{array}{c}
\bigcirc \\
nonumber j
\end{array}
\end{align*}
\]

Multiplication is given by concatenation of diagrams when the endpoints have the same colours, and is defined to be zero otherwise. The algebra is graded where generators are
defined to have degrees
\[ \deg \left( \begin{array}{c} \bullet \\ i \end{array} \right) = (\alpha_i, \alpha_i), \quad \deg \left( \begin{array}{c} \times \\ i \end{array} \right) = -(\alpha_i, \alpha_j). \]  

(1.13)

For \( \nu = \sum_{i \in I} \nu_i \cdot i \in \mathbb{N}[I] \) let \( \text{Seq}(\nu) \) be the set of all sequences of vertices \( i = i_1 \ldots i_m \) where \( i_r \in I \) for each \( r \) and vertex \( i \) appears \( \nu_i \) times in the sequence. The length \( m \) of the sequence is equal to \( |\nu| = \sum_{i \in I} \nu_i \). It is sometimes convenient to identify \( \nu = \sum_{i \in I} \nu_i \cdot i \in \mathbb{N}[I] \) as \( \nu \in \sum_{i \in I} \nu_i \alpha_i \in Q_+ = \oplus_{i \in I} \mathbb{Z}_{\geq 0} \alpha_i \). The algebra \( R \) has a decomposition
\[ R = \bigoplus_{\nu \in \mathbb{N}[I]} R(\nu) \]  

(1.14)

where \( R(\nu) \) is the subalgebra generated by diagrams that contain \( \nu_i \) strands coloured \( i \).

To convert from graphical to algebraic notation write
\[ 1_i := \begin{array}{c} i_1 \quad \ldots \quad i_k \quad \ldots \quad i_m \end{array} \]  

(1.15)

for \( i = i_1 i_2 \ldots i_m \in \text{Seq}(\nu) \). Elements \( 1_i \) are idempotents in the ring \( R(\nu) \) and when \( I \) is finite, \( 1_{\nu} \in R(\nu) \) is given by \( 1_{\nu} = \sum_{i \in \text{Seq}(\nu)} 1_i \). For \( 1 \leq r \leq m \) we denote
\[ x_{r,i} := \begin{array}{c} i_1 \quad \ldots \quad i_r \quad \ldots \quad i_m \end{array} \]  

(1.16)

with the dot positioned on the \( r \)-th strand counting from the left, and
\[ \psi_{r,i} := \begin{array}{c} i_1 \quad \ldots \quad i_r \quad \ldots \quad i_m \end{array} \]  

(1.17)

The algebra \( R(\nu) \) decomposes as a vector space
\[ R(\nu) = \bigoplus_{i,j \in \text{Seq}(\nu)} 1_j R(\nu) 1_i \]  

(1.18)

where \( 1_j R(\nu) 1_i \) is the \( k \)-vector space of all linear combinations of diagrams with sequence \( i \) at the bottom and sequence \( j \) at the top modulo the above relations.

The symmetric group \( S_m \) acts on \( \text{Seq}(\nu) \), \( m = |\nu| \) by permutations. Transposition \( s_r = (r, r + 1) \) switches entries \( i_r, i_{r+1} \) of \( i \). Thus, \( \psi_{r,i} \in 1_{s_r(i)} R(\nu) 1_i \). For each \( w \in S_m \) fix once and for all reduced expression \( \hat{w} = s_{w_1} s_{w_2} \ldots s_{w_t} \). Given \( w \in S_n \) we convert its reduced expression \( \hat{w} \) into an element of \( 1_{w(i)} R(\nu) 1_i \) denoted \( \psi_{\hat{w},i} = \psi_{w_1, s_{w_2} \ldots s_{w_t}(i)} \ldots \psi_{w_t-1, s_{w_t}(i)} \psi_{w_t, i} \).

To simplify notation we introduce elements
\[ x_r := \sum_{i \in \text{Seq}(\nu)} x_{r,i}, \quad \psi_{\hat{w}} = \sum_{i \in \text{Seq}(\nu)} \psi_{\hat{w},i} \]  

(1.19)

so that \( x_r 1_i = 1_i x_r = x_{r,i} \) and \( \psi_{\hat{w}} 1_i = 1_{w(i)} \psi_{\hat{w}} = \psi_{\hat{w}, i} \). This allows us to write the definition of the algebra \( R(\nu) \) as follows:
For \( \nu \in \mathbb{N}[I] \) with \(|\nu| = m\), let \( R(\nu) \) denote the associative, \( k \)-algebra on generators

\[
\begin{align*}
1_i & \quad \text{for } i \in \text{Seq}(\nu) \\
x_r & \quad \text{for } 1 \leq r \leq m \\
\psi_r & \quad \text{for } 1 \leq r \leq m - 1
\end{align*}
\] (1.20) (1.21) (1.22)

subject to the following relations for \( i, j \in \text{Seq}(\nu) \):

\[
\begin{align*}
1_i 1_j &= \delta_{i,j} 1_i, \quad (1.23) \\
x_r 1_i &= 1_i x_r, \quad (1.24) \\
\psi_r 1_i &= 1_{s_r(i)} \psi_r, \quad (1.25) \\
x_r x_t &= x_t x_r, \quad (1.26) \\
\psi_r \psi_t &= \psi_t \psi_r & \text{if } |r - t| > 1, \quad (1.27)
\end{align*}
\]

\[
\begin{align*}
\psi_r \psi_r 1_i &= \begin{cases} 
1_i & \text{if } i_r = i_{r+1} \\
\left(x_r^{-(i_r,i_{r+1})} + x_r^{-(i_{r+1},i_r)}\right) 1_i & \text{if } (\alpha_{i_r}, \alpha_{i_{r+1}}) = 0 \text{ and } i_r \neq i_{r+1},
\end{cases} \\
(\psi_r \psi_r + \psi_r \psi_{r+1}) 1_i &= \sum_{t=0}^{-(i_r,i_{r+1})-1} x_r^{-(i_r,i_{r+1})-1-t} x_t x_r^{-(i_r,i_{r+1})-1-t} 1_i \quad \text{if } i_r = i_{r+2} \text{ and } (\alpha_{i_r}, \alpha_{i_{r+1}}) \neq 0 \quad (1.28) \\
(\psi_r x_t - x_{s_r(t)} \psi_r) 1_i &= \begin{cases} 
1_i & \text{if } t = r \text{ and } i_r = i_{r+1} \\
-1_i & \text{if } t = r + 1 \text{ and } i_r = i_{r+1} \\
0 & \text{otherwise},
\end{cases} \quad (1.29)
\end{align*}
\]

**Remark 1.3.** For \( i, j \in \text{Seq}(\nu) \) let \( j S_i \) be the subset of \( S_m \) consisting of permutations \( w \) that take \( i \) to \( j \) via the standard action of permutations on sequences, defined above. Denote the subset \( \{\hat{w}\}_{w \in j S_i} \) of \( 1_j R(\nu) 1_i \) by \( j \hat{S}_i \). It was shown in [KL09, KL08a] that the vector space \( 1_j R(\nu) 1_i \) has a basis consisting of elements of the form

\[
\{\psi_{\hat{w}} \cdot x_1^{a_1} \cdots x_m^{a_m} 1_i \mid \hat{w} \in j \hat{S}_i, \ a_r \in \mathbb{Z}_{\geq 0}\}. \quad (1.31)
\]

Rouquier has defined a generalization of the algebras \( R \), where the relations depend on Hermitian matrices [Rou08].

### 1.1.4 The involution \( \sigma \)

Flipping a diagram about a vertical axis and simultaneously taking

\[
\begin{array}{c}
\times \\
i
\end{array}
\to
\begin{array}{c}
\times \\
i
\end{array}
\]

(in other words, multiplying the diagram by \((-1)^s\) where \( s \) is the number of times equally labelled strands intersect) is an involution \( \sigma = \sigma_\nu \) of \( R(\nu) \). Let \( w_0 \) denote the longest element...
of $S_{[\nu]}$. We can specify $\sigma$ algebraically as follows:

$$\sigma : R(\nu) \rightarrow R(\nu)$$

$$1_i \mapsto 1_{w_0(i)}$$

$$x_r \mapsto x_{|\nu|+1-r}$$

$$\psi_r \mapsto \psi_{|\nu|-r}.$$  

Given an $R(\nu)$-module $M$, we let $\sigma^* M$ denote the $R(\nu)$-module whose underlying set is $M$ but with twisted action $r \cdot u = \sigma(r)u$.

### 1.1.5 Characters

Define the character $\text{ch}(M)$ of a graded finitely-generated $R(\nu)$-module $M$ as

$$\text{ch}(M) = \sum_{i \in \text{Seq}(\nu)} \text{gdim}(1_i M) \cdot i.$$  

The character is an element of the free $\mathbb{Z}((q))$-module with the basis Seq($\nu$); when $M$ is finite dimensional, $\text{ch}(M)$ is an element of the free $\mathbb{Z}[q,q^{-1}]$-module with basis Seq($\nu$).

### 2 Functors on the modular category

#### 2.1 Categories of graded modules

We form the direct sum

$$R = \bigoplus_{\nu \in \mathbb{N}[I]} R(\nu).$$

This is a non-unital ring. Let $R(\nu)-\text{mod}$ be the category of finitely-generated graded left $R(\nu)$-modules, $R(\nu)-\text{fmod}$ be the category of finite dimensional graded $R(\nu)$-modules, and $R(\nu)-\text{pmod}$ be the category of projective objects in $R(\nu)-\text{mod}$. The morphisms in each of these three categories are grading-preserving module homomorphisms. By various categories of $R$-modules we will mean direct sums of corresponding categories of $R(\nu)$-modules:

$$R-\text{mod} \overset{\text{def}}{=} \bigoplus_{\nu \in \mathbb{N}[I]} R(\nu)-\text{mod},$$

$$R-\text{fmod} \overset{\text{def}}{=} \bigoplus_{\nu \in \mathbb{N}[I]} R(\nu)-\text{fmod},$$

$$R-\text{pmod} \overset{\text{def}}{=} \bigoplus_{\nu \in \mathbb{N}[I]} R(\nu)-\text{pmod}.$$  

By a simple $R(\nu)$-module we mean a simple object in the category $R(\nu)-\text{mod}$. In this paper we will be primarily concerned with category of finite dimensional $R(\nu)$-modules. Note that this category contains all of the simples. Henceforth, by an $R(\nu)$-module we will mean a finite dimensional graded $R(\nu)$-module, unless we say otherwise. We will denote the zero module by $0$. 

---

**FUNCTORS ON THE MODULAR CATEGORY**  

| Page 10 |

---
For any two $R(\nu)$-modules $M$, $N$ denote by $\text{Hom}(M,N)$ or $\text{Hom}_{R(\nu)}(M,N)$ the $k$-vector space of degree preserving homomorphisms, and by $\text{Hom}(M\{r\},N) = \text{Hom}(M,N\{-r\})$ the space of homogeneous homomorphisms of degree $r$. Here $N\{r\}$ denotes $N$ with the grading shifted up by $r$, so that $\text{ch}(N\{r\}) = q^r\text{ch}(N)$. Then we write

$$\text{HOM}(M,N) := \bigoplus_{r \in \mathbb{Z}} \text{Hom}(M,N\{r\}),$$

(2.1)

for the $\mathbb{Z}$-graded $k$-vector space of all $R(\nu)$-module morphisms.

Though it is essential to work with the degree preserving morphisms to get the $\mathbb{Z}[q, q^{-1}]$-module structure for the categorification theorems in [KL09, KL08a], for our purposes it will often be convenient to work with degree homogenous morphisms, but not necessarily degree preserving, in the various categories of graded modules introduced above. Since any homogenous morphism can be interpreted as a degree preserving morphism by shifting the grading on the source or target, all results stated using homogeneous morphisms can be recast as degree zero morphisms for an appropriate shift on the source or target.

### 2.2 Induction and Restriction functors

There is an inclusion of graded algebras

$$\iota_{\nu,\nu'} : R(\nu) \otimes R(\nu') \hookrightarrow R(\nu + \nu')$$

given graphically by putting the diagrams next to each other. It takes the idempotent $1_i \otimes 1_j$ to $1_{ij}$ and the unit element $1_{\nu} \otimes 1_{\nu'}$ to an idempotent of $R(\nu + \nu')$ denoted $1_{\nu,\nu'}$. This inclusion gives rise to restriction and induction functors denoted by $\text{Res}_{\nu,\nu'}$ and $\text{Ind}_{\nu,\nu'}$, respectively. When it is clear from the context, or when no confusion is likely to arise, we often simplify notation and write Res and Ind.

We can also consider these notions for any tuple $\underline{\nu} = (\nu^{(1)}, \nu^{(2)}, \ldots, \nu^{(k)})$ and sometimes refer to the image $R(\underline{\nu}) \overset{\text{def}}{=} \text{Im} \iota_{\underline{\nu}} \subseteq R(\nu^{(1)} + \cdots + \nu^{(k)})$ as a parabolic subalgebra of $R$. Let $\mu = \nu^{(1)} + \cdots + \nu^{(k)}$, $m = \sum \nu^{(r)}$, and $P = P_{\underline{\nu}}$ be the composition $(\mu^{(1)}, \ldots, \mu^{(k)})$ of $m$ so that $S_P$ is the corresponding parabolic subgroup of $S_m$. It follows from Remark 1.3 that $R(\mu)1_{\underline{\nu}}$ is a free right $R(\underline{\nu})$-module with basis $\{\psi_{\nu}1_{\underline{\nu}} | w \in S_m/S_P\}$ and $1_{\underline{\nu}}R(\mu)$ is a free left $R(\underline{\nu})$-module with basis $\{1_{\underline{\nu}}\psi_{\nu} | w \in S_P\backslash S_m\}$. By abuse of notation we will write $S_m/S_P$ to denote the minimal length left coset representatives, i.e. $\{w \in S_m | \ell(wu) = \ell(w) + \ell(v) \forall v \in S_P\}$, and $S_P\backslash S_m$ for the minimal length right coset representatives.

**Remark 2.1.** It is easy to see that if $M$ is an $R(\underline{\nu})$-module with basis $U$ consisting of weight vectors, then $\{\psi_{\nu} \otimes u | u \in U, w \in S_m/S_P\}$ is a weight basis of $\text{Ind}_{\underline{\nu}}M \overset{\text{def}}{=} R(\mu) \otimes_{R(\underline{\nu})} M$ (where for each $w$ we fix just one reduced expression $\bar{w}$). Note $R(\mu) \otimes_{R(\underline{\nu})} M = R(\mu)1_{\underline{\nu}} \otimes R(\underline{\nu})M$ since $\psi_{\nu}1_{\underline{\nu}} \otimes u = \psi_{\nu} \otimes 1_{\underline{\nu}}u = \psi_{\nu} \otimes u$.

Likewise, $\text{coInd} M \overset{\text{def}}{=} \text{HOM}_{R(\underline{\nu})}(R(\mu), M)$, which is discussed in detail in Section 2.3 below, and has basis $\{f_{w,u} | u \in U, w \in S_P\backslash S_m\}$ where $f_{w,u}(h\psi_{\nu}) = hu\delta_{w,v}$ for $h \in R(\underline{\nu})$ and $v \in S_P\backslash S_m$. Note $\text{Hom}_{R(\underline{\nu})}(R(\mu), M) = \text{Hom}_{R(\underline{\nu})}(1_{\underline{\nu}}R(\mu), M)$ since for $f \in \text{Hom}_{R(\underline{\nu})}(1_{\underline{\nu}}R(\mu), M)$, $t \in R(\mu)$, if $1_i \not\in R(\nu)$, i.e. $1_{\underline{\nu}}1_i = 0$, then

$$f(1.it) = 1_i f(1.it) = f(1_{\underline{\nu}}1_it) = f(0) = 0.$$
In other words, we can extend the domain of \( f \) to \( R(\mu) \) by setting \( f \) to be 0 on \( 1_i R(\mu) \) when \( 1_i \notin R(\nu) \). Likewise any \( f \in \text{Hom}_{R(\underline{\nu})}(R(\mu), M) \) must be 0 on the above set.

One extremely important property of the functor \( \text{Ind}_{\underline{\nu}} \) is that it is left adjoint to restriction. In other words, there is a functorial isomorphism

\[
\text{HOM}_{R(\mu)}(\text{Ind}_{\underline{\nu}} A, B) \cong \text{HOM}_{R(\underline{\nu})}(A, \text{Res}_{\underline{\nu}} B)
\]

where \( A, B \) are finite dimensional \( R(\underline{\nu}) \)- and \( R(\mu) \)-modules, respectively. We refer to this property as Frobenius reciprocity and use it repeatedly, often for deducing information about characters.

A shuffle \( k \) of a pair of sequences \( i \in \text{Seq}(\nu), j \in \text{Seq}(\nu') \) is a sequence together with a choice of subsequence isomorphic to \( i \) such that \( j \) is the complementary subsequence. Shuffles of \( i, j \) are in a bijection with the minimal length left coset representatives of \( S_\nu \times S_{\nu'} \) in \( S_{\nu + \nu'} \). We denote by \( \deg(i, j, k) \) the degree of the diagram in \( R(\nu + \nu') \) naturally associated to the shuffle, see an example below.

\[
\begin{array}{c}
\text{k} \\
\text{i} \quad \text{j}
\end{array}
\]

When the meaning is clear, we will also denote by \( k \) the underlying sequence of the shuffle \( k \).

Given two functions \( f \) and \( g \) on sets \( \text{Seq}(\nu) \) and \( \text{Seq}(\nu') \), respectively, with values in some commutative ring which contains \( \mathbb{Z}[q, q^{-1}] \), we define their (quantum) shuffle product \( f \circledast g \) (see [Lec04] and references therein) as a function on \( \text{Seq}(\nu + \nu') \) given by

\[
(f \circledast g)(k) = \sum_{i,j} q^{\deg(i, j, k)} f(i)g(j),
\]

the sum is over all ways to represent \( k \) as a shuffle of \( i \) and \( j \). Given \( M \in R(\nu)-\text{mod} \) and \( N \in R(\nu')-\text{mod} \) we construct the \( R(\nu) \otimes R(\nu') \)-module denoted by \( M \boxtimes N \) in the obvious way. It was shown in [KL09] that

\[
\text{ch}(\text{Ind}_{\nu,\nu'}(M \boxtimes N)) = \text{ch}(M) \cup \text{ch}(N).
\]

A similar statement holds for characters of induced \( R(\underline{\nu}) \)-modules by the transitivity of induction. This statement can be seen as a special case of the Mackey formula which describes a filtration on the restriction of an induced module (from one parabolic to another).

More precisely, in the case of maximal parabolics, the Mackey formula says the graded \( (R(\nu) \otimes R(\nu'), R(\nu'') \otimes R(\nu'''')) \)-bimodule \( 1_{\nu,\nu'} R_{1_{\nu',\nu''}} \) has a filtration over all \( \lambda \in \mathbb{N} / I \) with subquotients isomorphic to the graded bimodules

\[
(1_{\nu} R_{1_{\nu',\lambda,\lambda}} \otimes 1_{\nu'} R_{1_{\nu',\nu',\nu'' - \lambda}}) \otimes R' \left( 1_{\nu - \lambda, \nu', \nu'' + \lambda} R_{1_{\nu',\nu'' - \lambda}} \right) \{(-\lambda, \nu' + \lambda - \nu''') \},
\]

where \( R' = R(\nu - \lambda) \otimes R(\lambda) \otimes R(\nu' + \lambda - \nu''') \otimes R(\nu'' - \lambda) \), the bilinear form \((, )\) is defined in Section [1111] and such that every term above is in \( \mathbb{N} / I \). There is a natural generalization of this statement to arbitrary parabolic subalgebras.
2.3 Co-induction

In this section, we examine the right adjoint to restriction, the co-induction functor denoted coInd, and discuss the relationship between Ind and coInd, following the work of [Vaz99].

Using the notation of the previous section, set \( \text{coInd}_{R(\nu)} - := \text{HOM}_{R(\nu)}(R(\mu), -) \) endowed with the module structure \((r \circ f)(t) = f(tr)\) for \(r, t \in R(\mu)\), \(f \in \text{coInd}_{R(\nu)} - \). Now there is a functorial isomorphism

\[
\text{HOM}_{R(\mu)}(B, \text{coInd}_A) \cong \text{HOM}_{R(\nu)}(\text{Res}_\nu B, A)
\]

where \(A, B\) are finite dimensional modules.

Just as \(w_0\) denotes the longest element of \(S_m\), let \(w_P \in S_P\) denote the longest element of the parabolic subgroup, with notation as above. Let \(y = w_Pw_0\) in the discussion below. Note that \(y\) is a minimal length right coset representative for \(S_P \setminus S_m\) and corresponds to the “longest shuffle”.

Observe that for any \(r\) such that \(s_r \in S_P\), \(\ell(wPs_rw_P) = 1 = \ell(w_0s_rw_0)\) and further

\[
\ell(s_r y) = 1 + \ell(y) = \ell(wPs_rw_P y) = \ell(yw_0s_rw_0)
\]

as in fact

\[
(wPs_rw_P y) = wPs_rw_Pw_Pw_0 = w_Pw_0w_0s_rw_0 = y(w_0s_rw_0).
\]

Set

\[
\sigma_{\nu} := \sigma_{\nu(1)} \otimes \sigma_{\nu(2)} \otimes \cdots \otimes \sigma_{\nu(k)}
\]

where \(\sigma_{\nu} : R(\nu) \rightarrow R(\nu)\) is the involution defined in Section 1.1.4.

When clear from context, let us just call \(\sigma = \sigma_{\mu}\). Then note, \(\sigma(1j) = 1_{w_0(j)}\), \(\sigma(x_r) = x_{w_0(r)}\), \(\sigma(\psi_r) = \psi_{w_0s_rw_0}\) with similar equations for \(\sigma_{\nu}\), where \(S_\mu\) acts on Seq(\(\mu\)) in the usual fashion \(w(i_1, \ldots, i_m) = (i_{w^{-1}(1)}, \ldots, i_{w^{-1}(m)})\). In what follows, for bookkeeping purposes, we will write \(u \in M\), but \(\tilde{u} \in \sigma^*M\) so that the \(\sigma\)-twisted action can be described as \(ru = \sigma(r)u\).

**Theorem 2.2.**

1. Let \(M\) be a finite dimensional \(R(\nu)\)-module. Then \(\text{Ind}_{\nu}^\mu M \cong \sigma_{\mu}^*(\text{coInd}_{\nu}^\mu(\sigma_{\nu}M))\{\deg(y)\}\).

2. Let \(A\) be a finite dimensional \(R(\nu)\)-module and \(B\) a finite dimensional \(R(\eta)\)-module.

Then there is a homogeneous, but not degree-preserving, isomorphism \(\text{Ind}_{\nu,\eta}^{\nu+\eta} A \boxtimes B \cong \text{coInd}_{\eta,\nu}^{\nu+\eta} B \boxtimes A\).

**Proof.** We first note that [2] follows from a special case of [1]. To prove [1], we first construct a \(R(\nu)\)-module map

\[
M \xrightarrow{F} \text{Res}_\nu^\mu(\sigma_{\mu}^*\text{coInd}_\nu^\mu(\sigma_{\nu}^*M))
\]

with \(\deg(F) = -\deg(y)\) and then the induced map

\[
\text{Ind}_\nu^\mu M \xrightarrow{\mathcal{F}} \sigma_{\mu}^*\text{coInd}_\nu^\mu(\sigma_{\nu}^*M)
\]

also has \(\deg(\mathcal{F}) = -\deg(y)\) and surjective as the image of \(F\) generates the target over \(R(\mu)\). Since the two modules in question have the same dimension, they are isomorphic.
Given \( u \in M \) define \( f_u \in \text{HOM}_{R(\nu)}(R(\mu),\sigma^*_\nu M) \) by

\[
f_u(\psi_{\bar{w}}) = \bar{u}\delta_{w,y}
\]

where \( w \in S_P \setminus S_m \) ranges over the minimal length right coset representatives, \( \bar{w} \) is a fixed reduced expression, and \( y = w_P w_0 \). Observe that \( \deg(f_u) = \deg(u) - \deg(y) \). We extend \( f_u \) to an \( R(\nu) \)-map by declaring \( f_u(h\psi_{\bar{w}}) = hf_u(\psi_{\bar{w}}) \) for \( h \in R(\nu) \) which is viable by Remark 2.1. Now we define

\[
F : M \to \sigma^*_\nu \text{coInd}^0(\sigma^*_\nu M)
\]

\[
u \mapsto \frac{f_u}{u}
\]

and check it is an \( R(\nu) \)-map. This map is homogeneous with \( \deg(F) = -\deg(y) \). Note that \( f_{u+u'} = f_u + f_{u'} \) so it suffices to consider only degree homogeneous weight vectors \( u \in M \), i.e. there exists \( i \) such that \( 1_i\bar{u} = \bar{u} \) (and so \( 1_{w_P(i)} u = u \)). In this case \( f_u(1_j\psi_{\bar{w}}) = \bar{u}\delta_{w,y}\delta_{i,j} \), and this holds regardless of whether \( 1_j \in R(\nu) \) by Remark 2.1. In fact, by abuse of notation, we may write \( 1_j\bar{u} = \bar{u}\delta_{i,j} \) even when \( 1_j \notin R(\nu) \).

We need to show \( F(hu) = h \odot F(u) \) for \( h = 1_j, h = x_r \) for all \( r \), and \( h = \psi_r \) for \( r \) such that \( s_r \in S_P \). From now on, assume \( u \) is a weight vector as above.

Case 1) We evaluate

\[
(1_jF(u))(\psi_{\bar{w}}) = 1_j \circ \frac{f_u}{1_ju} = 1_j(\sigma^*_\nu u) \circ \frac{f_u}{1_ju} \psi_{\bar{w}}
\]

\[
= \frac{f_u}{1_ju}(1_j(1_ju)\psi_{\bar{w}})
\]

\[
= \frac{f_u}{1_ju}(1_ju\psi_{\bar{w}})
\]

\[
= \frac{f_u}{1_ju}(1_ju\psi_{\bar{w}})
\]

\[
= \frac{f_u}{1_ju}(1_ju\psi_{\bar{w}})
\]

\[
= f_{1_ju}(\psi_{\bar{w}}) = F(1_ju)(\psi_{\bar{w}})
\]

so that \( 1_jF(u) = F(1_ju) \).

Case 2) We compute

\[
(x_rF(u))(\psi_{\bar{w}}) = (x_r \circ \frac{f_u}{1_ju} \circ \psi_{\bar{w}} = (x_r(1_ju) \circ \frac{f_u}{1_ju} \psi_{\bar{w}})
\]

\[
= \frac{f_u}{1_ju}x_{w_0(r)}(\psi_{\bar{w}})
\]

\[
= \frac{f_u}{1_ju}(x_{w_0(r)}(\psi_{\bar{w}}) + \text{lower terms})
\]

\[
= \left\{ \begin{array}{ll}
\frac{f_u}{1_ju}(x_{w_0(r)}(\psi_{\bar{w}}) & \text{if } w = y \\
0 & \text{else}
\end{array} \right.
\]

\[
= \left\{ \begin{array}{ll}
x_{w_0(r)}u & \text{if } w = y \\
0 & \text{else}
\end{array} \right.
\]

so that \( F(x_ru) = x_rF(u) \) for any \( r \).

Note that with respect to \( \psi_{\bar{w}} \), by lower terms we mean elements of \( \{ h\psi_{\bar{w}} \mid h \in R(\nu), \ell(v) < \ell(w) \} \).
Case 3) Let \( r \) be such that \( s_r \in S_P \). Recall that then \( w_PS_rw_P \in S_P \) as well. We compute

\[
\psi_r F(u)(\psi_{\bar{w}}) = (\psi_r \circ \bar{f}_u)(\psi_{\bar{w}}) = \bar{f}_u(\psi_{\bar{w}} \sigma_\mu(\psi_r)) = \bar{f}_u(\psi_{\bar{w}} \psi_{w_PS_rw_P}) \]

\[
= \left\{ \begin{array}{ll}
\bar{f}_u(\psi_{w_PS_rw_P} \psi_{\bar{y}} + \text{lower terms}) & \text{if } w = y \\
\bar{f}_u(\text{lower terms}) & \text{if } w \neq y \\
\end{array} \right.
\]

\[
= \left\{ \begin{array}{ll}
\psi_{w_PS_rw_P} \bar{f}_u(\psi_{\bar{y}}) & \text{if } w = y \\
0 & \text{else}
\end{array} \right.
\]

\[
= \left\{ \begin{array}{ll}
\sigma_\nu(\psi_r) \bar{u} & \text{if } w = y \\
0 & \text{else}
\end{array} \right.
\]

\[
= \bar{f}_v \psi_r u(\psi_{\bar{w}}) \quad \text{if } w = y
\]

\[
= F(\psi_r u)(\psi_{\bar{w}}),
\]

so that \( \psi_r F(u) = F(\psi_r u) \).

Thus, \( F \) is indeed an \( R(\nu) \)-map. Note the image of \( F \) contains all of the \( \bar{f}_u \) as \( u \) ranges over a weight basis of \( M \). Hence the image of \( F \): \( \text{Ind}_\nu^\chi M \rightarrow \sigma_\nu^* \text{coInd}_\nu^\chi(\sigma_\nu^* M) \) contains all of the \( h \circ \bar{f}_u \) for \( h \in R(\mu) \).

We shall argue this contains a basis of \( \sigma_\nu^* \text{coInd}_\nu^\chi(\sigma_\nu^* M) \) which will show that \( F \) is surjective. Recall from Remark 2.1 that \( \sigma_\nu^* \text{coInd}_\nu^\chi(\sigma_\nu^* M) \) has a basis of “bump functions” of the form \( \bar{f}_w \) and in this notation \( \bar{f}_u = \bar{f}_{y/u} \). As in [Vaz99], we can show the \( \psi_v \circ \bar{f}_{y/u} \) for appropriate \( v \) are triangular with respect to the \( \{ \bar{f}_{w/u} \} \) so contain a basis. Since the dimensions of the induced and coinduced modules are the same, \( F \) is in fact an isomorphism.

\[\square\]

2.4 Simple \( R(mi) \)-modules

Simple modules for the algebra \( R(mi) \)-modules play a key role in this paper. There are several constructions of these modules.

For example, let \( i = i^m \) and consider the graded algebra \( \mathbb{k}[x_{1,i}, \ldots, x_{m,i}] \) with \( \deg(x_{t,i}) = (\alpha_i, \alpha_i) \). Up to isomorphism and grading shift, for each \( r \in \mathbb{Z} \), there is a unique graded irreducible module \( L(i^m)\{r\} \) for the ring \( R(mi) \) given as the quotient of \( \mathbb{k}[x_{1,i}, \ldots, x_{m,i}] \) by the ideal of symmetric polynomials, see [KL09]. This module can alternatively be described as the induced module from the trivial \( R' \)-module, where \( R' \) is the subalgebra of \( R(mi) \) spanned by \( \psi_{1,i}, \ldots, \psi_{m-1,i} \) and symmetric polynomials in \( \mathbb{k}[x_{1,i}, \ldots, x_{m,i}] \).

Furthermore, this irreducible module \( L(i^m)\{r\} \) is isomorphic, by a homogeneous but not degree preserving isomorphism, to the module induced from the one-dimensional graded module \( L = L(i) \otimes \cdots \otimes L(i) \) over \( \mathbb{k}[x_{1,i}, \ldots, x_{m,i}] \) on which \( x_{1,i}, \ldots, x_{m,i} \) all act trivially. In this paper we fix the grading shift on this unique simple module \( L(i^m)\{r\} \) so that

\[\text{ch}(L(i^m)) = [m]_i^m.\] (2.12)

In [Lau09 Proposition 2.8], Lauda shows not only that for any \( u \in L(i^m) \), \( 1 \leq r \leq m \), and \( k \geq m \) that \( x^k_r u = 0 \), but also that there exists \( \bar{u} \in L(i^m) \) such that \( x^m_r \bar{u} \neq 0 \) for all \( r \).

See the third statement in Section 2.5.1 for some of the important properties of \( L(i^m) \), such as its behaviour under the induction and restriction functors.
2.5 Refining the restriction functor

For $M$ in $R(\nu)\text{-mod}$ and $i \in I$ let

$$\Delta_i M = (1_{\nu-i} \otimes 1_i) M = \text{Res}_{\nu-i,i} M,$$

and, more generally,

$$\Delta_{\nu} M = (1_{\nu-ni} \otimes 1_{ni}) M = \text{Res}_{\nu-ni,ni} M.$$

We view $\Delta_{\nu}$ as a functor into the category $R(\nu-ni) \otimes R(ni)\text{-mod}$. By Frobenius reciprocity, there are functorial isomorphisms

$$\text{HOM}_{R(\nu)}(\text{Ind}_{\nu-ni,ni} N \boxtimes L(i^n), M) \cong \text{HOM}_{R(\nu-ni) \otimes R(ni)}(N \boxtimes L(i^n), \Delta_{\nu} M),$$

(2.13)

for $M$ as above and $N \in R(\nu-ni)\text{-mod}$.

Define

$$e_i := \text{Res}_{\nu-i,i} \circ \Delta_i : R(\nu)\text{-mod} \to R(\nu-i)\text{-mod}$$

and for $M$ an irreducible $R(\nu)$-module, set

$$\tilde{e}_i M := \text{soc} e_i M,$$

(2.15)

$$\tilde{f}_i M := \text{cosoc} \text{ Ind}_{\nu,i}^{\nu+i} M \boxtimes L(i),$$

(2.16)

$$\varepsilon_i(M) := \max \{n \geq 0 \mid \tilde{e}_i^n M \neq 0 \}.$$  

(2.17)

We also define their so-called $\sigma$-symmetric versions, which are indicated with a $\vee$. Note that $\sigma^*(\Delta_i(\sigma^* M)) = \text{Res}_{\nu-i,i} M$. Set

$$e_i^\vee := \text{Res}_{\nu-i,i}^\nu \circ \text{Res}_{\nu-i,i} : R(\nu)\text{-mod} \to R(\nu-i)\text{-mod},$$

(2.18)

$$\tilde{e}_i^\vee M := \sigma^*(\tilde{e}_i(\sigma^* M)) = \text{soc} e_i^\vee M,$$

(2.19)

$$\tilde{f}_i^\vee M := \sigma^*(\tilde{f}_i(\sigma^* M)) = \text{cosoc} \text{ Ind}_{\nu,i}^{\nu+i} L(i) \boxtimes M,$$

(2.20)

$$\varepsilon_i^\vee(M) := \varepsilon_i(\sigma^* M) = \max \{m \geq 0 \mid (\tilde{e}_i^\vee)^m M \neq 0 \}.$$  

(2.21)

Observe that the functors $e_i$ and $e_i^\vee$ are exact. It is a theorem of [KL09] that if $M$ is irreducible, so are $\tilde{f}_i M$ and $\tilde{e}_i M$ (so long as the latter is nonzero), and likewise for $\tilde{f}_i^\vee M$ and $\tilde{e}_i^\vee M$. This is stated below along with other key properties.

2.5.1 Properties of the functors $\tilde{e}_i$ and $\tilde{f}_i$ on simple modules

In this section we give a long list of results that were proved in [KL09], which extend to the symmetrizable case by the results in [KL08a], about simple $R(\nu)$-modules and their behaviour under induction and restriction. We will use them freely throughout the paper.

1. $\text{ch}(\Delta_{\nu} M) = \sum_{j \in \text{Seq}(\nu-ni)} \text{ch}(M, j^i^n) \cdot j$,

where we view $\Delta_{\nu} M$ as a module over the subalgebra $R(\nu-ni)$ of $R(\nu-ni) \otimes R(ni)$.

2. Let $N \in R(\nu)\text{-mod}$ be irreducible and $M = \text{Ind}_{\nu,ni} N \boxtimes L(i^n)$. Let $\varepsilon = \varepsilon_i(N)$. 

16
THE ALGEBRAS $R^\Lambda(\nu)$

1. For all $i \in \text{Seq}(\nu)$ and any $\Lambda \in P^+$ the elements $x_{r,i}$ are nilpotent for all $1 \leq r \leq |\nu|$.

2. The algebra $R^\Lambda(\nu)$ is finite dimensional.
Proof. The proof of the first claim is by induction on the length of the sequence $i$. The base case is immediate from the definition (2.22) of $R^A(\nu)$. For the induction step we assume the claim holds for all sequences $i$ of length of $m - 1$ and prove the result for sequences of length $m$. For $j \in I$ write $ij$ for the concatenated sequence of length $m$ obtained by adding $j$ to the end of $i$. Restricting $R_{ij} \to R_{1i} \otimes R_{1j}$ implies $x_{r,ij}$ is nilpotent for all $1 \leq r < m$. Thus it suffices to prove that $x_{m,ij}$ is nilpotent.

Let $i = i_1 \ldots i_{m-1}$ and assume for simplicity of notation that $i_{m-1} = i$ for some $i \in I$. If $(\alpha_i, \alpha_j) < 0$, then by the inductive hypothesis for some $N, N' > 0$ we have $x_{m-1,ij}^N = 0$ and $x_{m-1,ij'}^N = 0$, where $i' = i_1 \ldots i_{m-3}i_{m-2}j$, so that adding $j$ to the end of the sequence $i$ we have $x_{m-1,ij}^N = 0$, and adding an $i$ to the end of the sequence $i'$ we have $x_{m-1,s_{m-1}(ij)}^{N'} = 0$.

Since $x_{m-1,ij}^N = 0$ we certainly have $x_{m-1,ij}^{N_{ai_j}} = 0$. Then $x_{m,ij}^{N_{ai_j} + N'} = 0$, since by (1.7) (working locally around the last two strands) we have

\[
\begin{array}{c}
N_{ai_j} + N' = (N-1)_{ai_j} + N' - a_{ij} - (N-1)_{ai_j} + N' \\
i & j \\
i & j
\end{array}
\]  

(2.24)

The first diagram on the right-hand-side is zero since we can slide the dots using (1.8) and then use our assumption $x_{m-1,ij}^{N_{ai_j}} = 0$. Then either $N = 1$ and the second diagram is also zero by assumption, or $N > 1$ and we can iterate $N$-times the application of (1.7) to show

\[
\begin{array}{c}
N_{ai_j} + N' = (N-1)_{ai_j} + N' - (-1)^N N_{ai_j} - N' \\
i & j \\
i & j
\end{array}
\]  

(2.25)

Sliding the $N'$ dots on the first diagram on the right-hand-side using (1.8), the entire right side is zero by our assumptions on $N$, $N'$.

If $(\alpha_i, \alpha_j) = 0$ then by the inductive hypothesis there exist an $N$ with $x_{m,s_{m-1}(i')}^N = 0$ for $i' = i_1 \ldots i_{m-3}i_{m-2}j$, so that (1.7) and (1.8) imply $x_{m,ij} = \psi_{m-1}x_{m-1,ij}^N = 0$. If $i = j$ then an identical proof as in [BK08, Lemma 2.1] or [Lau09, Proposition 2.9 (i)] shows that $x_{m,ij}$ is nilpotent. Therefore, $x_{r,ij}$ is nilpotent for all $1 \leq r \leq m$ and we have proven the induction step.

The second claim in the Proposition follows from the first since $R^A(\nu)$ is spanned by $\{ \psi_{\bar{w}} \cdot x_{1,i}^{n_1} \cdot \ldots \cdot x_{m,i}^{n_m} | w \in S_m, n_1, \ldots, n_m \geq 0 \}$ and by the first claim only finitely many of the $x_{r,ij}$ are nonzero for each $1 \leq r \leq m$.

In terms of the graphical calculus the cyclotomic quotient $R^A(\nu)$ is the quotient of $R(\nu)$ by the ideal generated by

\[
\begin{array}{c}
\lambda_i & \lambda_i & \ldots & \lambda_i \\\ni_1 & i_2 & \ldots & i_m
\end{array} = 0
\]  

(2.26)

over all sequences $i$ in $\text{Seq}(\nu)$. 

For bookkeeping purposes we will denote $R^\Lambda(\nu)$ modules by $\mathcal{M}$ but $R(\nu)$-modules by $M$. We introduce functors

$$\text{infl}_\Lambda: R^\Lambda(\nu)-\text{mod} \to R(\nu)-\text{fmod} \quad \text{pr}_\Lambda: R(\nu)-\text{fmod} \to R^\Lambda(\nu)-\text{mod} \quad (2.27)$$

where $\text{infl}_\Lambda$ is the inflation along the epimorphism $R(\nu) \to R^\Lambda(\nu)$, so that $\mathcal{M} = \text{infl}_\Lambda M$ on the level of sets. If $\mathcal{M}, \mathcal{N}$ are $R^\Lambda(\nu)$-modules, then

$$\text{Hom}_{R^\Lambda(\nu)}(\mathcal{M}, \mathcal{N}) \cong \text{Hom}_{R(\nu)}(\text{infl}_\Lambda M, \text{infl}_\Lambda N).$$

Note $\mathcal{M}$ is irreducible if and only if $\text{infl}_\Lambda M$ is. We define $\text{pr}_\Lambda M = M/\mathcal{J}^\Lambda M$. If $M$ is irreducible then $\text{pr}_\Lambda M$ is either irreducible or zero. Observe $\text{infl}_\Lambda$ is an exact functor and its left adjoint is $\text{pr}_\Lambda$ which is only right exact.

A careful study of the modules $L(i^n)$ yields that for simple modules $M$, the algebraic statement $\mathcal{J}^\Lambda M = 0$ is equivalent to the measurement that $\varepsilon_i^\Lambda(M) \leq \lambda_i$ for all $i \in I$, see [Lau09, Proposition 2.8]. Likewise $\mathcal{J}^\Lambda M = M$ if and only if there exists some $i \in I$ such that $\varepsilon_i^\Lambda(M) > \lambda_i$. Hence, given a finite dimensional $R(\nu)$-module $M$, there exists a $\Lambda \in P^+$ such that $\mathcal{J}^\Lambda M = 0$, so that we can identify $M$ with the $R^\Lambda(\nu)$-module $\text{pr}_\Lambda M$. For instance, take any $\Lambda = \sum_{i \in I} m_i \lambda_i$ with $m_i > \text{dim}_k M$. We deduce the following remark.

**Remark 2.4.** Let $M$ be a simple $R(\nu)$-module. Then $\text{pr}_\Lambda M \neq 0$ iff $\varepsilon_i^\Lambda(M) \leq \lambda_i$ for all $i \in I$.

Let $\mathcal{M}$ be an irreducible $R^\Lambda(\nu)$-module. As in Section 2.3 define

$$e_i^\Lambda \mathcal{M} = \text{pr}_\Lambda \circ e_i \circ \text{infl}_\Lambda \mathcal{M}: R^\Lambda(\nu)-\text{mod} \to R^\Lambda(\nu-i)-\text{mod}$$

$$\tilde{e}_i^\Lambda \mathcal{M} = \text{pr}_\Lambda \circ \varepsilon_i \circ \text{infl}_\Lambda \mathcal{M}$$

$$\tilde{f}_i^\Lambda \mathcal{M} = \text{pr}_\Lambda \circ \tilde{f}_i \circ \text{infl}_\Lambda \mathcal{M}$$

$$\varepsilon_i^\Lambda(\mathcal{M}) = \varepsilon_i(\text{infl}_\Lambda \mathcal{M})$$

Let $\mathcal{M} \in R^\Lambda(\nu)-\text{mod}$ and $M = \text{infl}_\Lambda \mathcal{M}$. Then $\text{pr}_\Lambda M = \mathcal{M}$. Since $\mathcal{J}^\Lambda M = 0$ then $\mathcal{J}^\Lambda \varepsilon_i^\Lambda M = 0$ too, so that $e_i^\Lambda \mathcal{M}$ is an $R(\nu-i)^\Lambda$-module with $\text{infl}_\Lambda(e_i^\Lambda \mathcal{M}) = e_i M$. In particular, $\text{dim}_k e_i^\Lambda \mathcal{M} = \text{dim}_k e_i M$. If furthermore $\mathcal{M}$ is irreducible, then $\tilde{e}_i^\Lambda \mathcal{M} = \text{soc} e_i^\Lambda \mathcal{M}$.

### 2.7 Ungraded modules

Write $R-\text{mod}$, $R-\text{fmod}$, and $R-\text{pmod}$ for the corresponding categories of ungraded modules. There are forgetful functors

$$R-\text{mod} \to R-\text{mod}, \quad R-\text{fmod} \to R-\text{fmod}, \quad R-\text{pmod} \to R-\text{pmod} \quad (2.28)$$

given by sending a module $M$ to the module $M$ obtained by forgetting the gradings, and mapping $\text{HOM}(M, N)$ to $\text{Hom}(M, N)$. Essentially not much is lost working with the ungraded modules since given an irreducible module $M \in R-\text{fmod}$, then $M$ is irreducible in $R-\text{fmod}$ [NO04, Theorem 4.4.4(\nu)]. Likewise, since $R^\Lambda(\nu)$ is a finite dimensional $k$-algebra, if $K \in R^\Lambda(\nu)-\text{fmod}$ is irreducible, then there exists an irreducible $L \in R^\Lambda(\nu)-\text{fmod}$ such that $L \cong K$. Furthermore, $L$ is unique up to isomorphism and grading shift, see [NO04, Theorem 9.6.8]. Since any finite-dimensional $R(\nu)$-module $M$ can be identified with the $R^\Lambda(\nu)$-module $\text{pr}_\Lambda M$ for some $\Lambda$, we also have that for any irreducible $K \in R(\nu)-\text{fmod}$ there exists a unique, up to grading shift and isomorphism, irreducible $L \in R(\nu)-\text{fmod}$ such that $L = K$. 

3 Operators on the Grothendieck group

The Grothendieck groups

\[ K_0(R) = \bigoplus_{\nu \in \mathbb{N}[I]} K_0(R^\nu_{-\text{pmod}}), \quad G_0(R) = \bigoplus_{\nu \in \mathbb{N}[I]} G_0(R^\nu_{-\text{fmod}}) \]

\[ K_0(R^\Lambda) = \bigoplus_{\nu \in \mathbb{N}[I]} K_0(R^\Lambda^\nu_{-\text{pmod}}), \quad G_0(R^\Lambda) = \bigoplus_{\nu \in \mathbb{N}[I]} G_0(R^\Lambda^\nu_{-\text{fmod}}) \]

are the direct sums of Grothendieck groups \( R(\nu_{-\text{pmod}}), R(\nu_{-\text{fmod}}), R^\Lambda(\nu_{-\text{pmod}}), R^\Lambda(\nu_{-\text{fmod}}) \) respectively. The Grothendieck groups have the structure of a \( \text{Seq}(\nu) \)-module given by shifting the grading, \( q[M] = [M\{1\}] \).

The functor \( e_i \) defined in (2.13) is clearly exact so descends to an operator on the Grothendieck group

\[ G_0(R(\nu_{-\text{mod}})) \rightarrow G_0(R(\nu_i)_{-\text{mod}}) \] (3.1)

and hence

\[ e_i : G_0(R) \rightarrow G_0(R). \] (3.2)

By abuse of notation, we will also call this operator \( e_i \). Likewise \( e_i^\Lambda : G_0(R^\Lambda) \rightarrow G_0(R^\Lambda) \).

We also define divided powers

\[ e_i^{(r)} : G_0(R) \rightarrow G_0(R) \] (3.3)

given by \( e_i^{(r)}[M] = \frac{1}{r!_i} e_i^r[M] \), which are well-defined by Section 2.4.

For irreducible \( M \), we define \( \tilde{e}_i[M] = [\tilde{e}_iM], \tilde{f}_i[M] = [\tilde{f}_iM] \), and extend the action linearly.

An important result from \[ KL09 \] is that the character map

\[ ch : G_0(R(\nu_{-\text{mod}})) \rightarrow \mathbb{Z}[q,q^{-1}]\text{Seq}(\nu) \]

is injective. In other words, for any module \( M \), we have that \( [M] \in G_0(R) \) is determined by \( ch(M) \). This fact was used in \[ KL09 \] to give an explicit isomorphism

\[ \mathcal{A} f \rightarrow K_0(R) \] (3.4)

as (twisted) \( \mathbb{Z}[q,q^{-1}] \)-bialgebras.

Let us consider the maximal commutative subalgebra

\[ \bigoplus_{i \in \text{Seq}(\nu)} \mathbb{k}[x_{1,i}, \ldots, x_{m,i}] \subseteq R(\nu). \]

This ring was called \( \mathcal{P}o_{\nu} \) in \[ KL09 \]. In the notation of this paper, we could also denote it \( \mathbb{k}[x_1, \ldots, x_m]_{1\nu} \). Its irreducible submodules are one dimensional, and up to grading shift are isomorphic to \( L(i_1) \otimes L(i_2) \otimes \cdots \otimes L(i_m) \) and in this way correspond to \( \mathbb{i} = (i_1, \ldots, i_m) \in \text{Seq}(\nu) \). In this way, we may identify \( G_0(\mathbb{k}[x_1, \ldots, x_m]_{1\nu_{-\text{fmod}}}) \) with \( \mathbb{Z}[q,q^{-1}]\text{Seq}(\nu) \). Hence one may rephrase the injectivity of the character map as saying that a module is determined by its restriction to that maximal commutative subalgebra, in their respective Grothendieck groups.

Note that the isomorphism classes of simple modules, up to grading shift, form a basis of \( G_0(R) \). One of the main results of this paper is that we compute the rank of \( G_0(R^\Lambda(\nu_{-\text{fmod}})) \) by realizing a crystal structure on \( G_0(R^\Lambda) \) and identifying it as the highest weight crystal \( \mathcal{B}(\Lambda) \). In this language, we see the operators above become crystal operators.
4 Reminders on crystals

A main result of this paper is the realization of a crystal graph structure on $G_0(R)$ which we identify as the crystal $B(\infty)$. Hence, we need to remind the reader of the language and notation of crystals.

4.1 Monoidal category of crystals

We recall the tensor category of crystals following Kashiwara [Kas95], see also [Kas90b, Kas91, KS97].

A crystal is a set $B$ together with maps

- $\mathrm{wt}: B \to P$,
- $\varepsilon_i, \varphi_i: B \to \mathbb{Z} \cup \{\infty\}$ for $i \in I$,
- $\tilde{e}_i, \tilde{f}_i: B \to B \cup \{0\}$ for $i \in I$,

such that

(C1) $\varphi_i(b) = \varepsilon_i(b) + \langle h_i, \mathrm{wt}(b) \rangle$ for any $i$.

(C2) If $b \in B$ satisfies $\tilde{e}_ib \neq 0$, then

$$
\varepsilon_i(\tilde{e}_ib) = \varepsilon_i(b) - 1, \quad \varphi_i(\tilde{e}_ib) = \varphi_i(b) + 1, \quad \mathrm{wt}(\tilde{e}_ib) = \mathrm{wt}(b) + \alpha_i.
$$

(C3) If $b \in B$ satisfies $\tilde{f}_ib \neq 0$, then

$$
\varepsilon_i(\tilde{f}_ib) = \varepsilon_i(b) + 1, \quad \varphi_i(\tilde{f}_ib) = \varphi_i(b) - 1, \quad \mathrm{wt}(\tilde{f}_ib) = \mathrm{wt}(b) - \alpha_i.
$$

(C4) For $b_1, b_2 \in B$, $b_2 = \tilde{f}_ib_1$ if and only if $b_1 = \tilde{e}_ib_2$.

(C5) If $\varphi_i(b) = -\infty$, then $\tilde{e}_ib = \tilde{f}_ib = 0$.

If $B_1$ and $B_2$ are two crystals, then a morphism $\psi: B_1 \to B_2$ of crystals is a map

$$
\psi: B_1 \cup \{0\} \to B_2 \cup \{0\}
$$

satisfying the following properties:

(M1) $\psi(0) = 0$.

(M2) If $\psi(b) \neq 0$ for $b \in B_1$, then

$$
\mathrm{wt}(\psi(b)) = \mathrm{wt}(b), \quad \varepsilon_i(\psi(b)) = \varepsilon_i(b), \quad \varphi_i(\psi(b)) = \varphi_i(b).
$$

(M3) For $b \in B_1$ such that $\psi(b) \neq 0$ and $\psi(\tilde{e}_ib) \neq 0$, we have $\psi(\tilde{e}_ib) = \tilde{e}_i(\psi(b))$.

(M4) For $b \in B_1$ such that $\psi(b) \neq 0$ and $\psi(\tilde{f}_ib) \neq 0$, we have $\psi(\tilde{f}_ib) = \tilde{f}_i(\psi(b))$. 
A morphism $\psi$ of crystals is called strict if
\[ \psi e_i = \tilde{e}_i \psi, \quad \psi f_i = \tilde{f}_i \psi, \] (4.4)
and an embedding if $\psi$ is injective.

Given two crystals $B_1$ and $B_2$ their tensor product $B_1 \otimes B_2$ has underlying set $\{b_1 \otimes b_2; b_1 \in B_1, \ b_2 \in B_2\}$ where we identify $b_1 \otimes 0 = 0 \otimes b_2 = 0$. The crystal structure is given as follows:

\[
\begin{align*}
\text{wt}(b_1 \otimes b_2) &= \text{wt}(b_1) + \text{wt}(b_2), \\
\varepsilon_i(b_1 \otimes b_2) &= \max \max \{\varepsilon_i(b_1), \varepsilon_i(b_2) - \langle h_i, \text{wt}(b_1) \rangle\}, \\
\varphi_i(b_1 \otimes b_2) &= \max \{\varphi_i(b_1) + \langle h_i, \text{wt}(b_2) \rangle, \varphi_i(b_2)\}, \\
\tilde{e}_i(b_1 \otimes b_2) &= \begin{cases} 
\tilde{e}_i(b_1) \otimes b_2 & \text{if } \varphi_i(b_1) \geq \varepsilon_i(b_2) \\
 b_1 \otimes \tilde{e}_i b_2 & \text{if } \varphi_i(b_1) < \varepsilon_i(b_2), 
\end{cases} \\
\tilde{f}_i(b_1 \otimes b_2) &= \begin{cases} 
\tilde{f}_i(b_1) \otimes b_2 & \text{if } \varphi_i(b_1) > \varepsilon_i(b_2) \\
 b_1 \otimes \tilde{f}_i b_2 & \text{if } \varphi_i(b_1) \leq \varepsilon_i(b_2). 
\end{cases}
\end{align*}
\] (4.5) (4.6) (4.7) (4.8) (4.9)

**Example 4.1** ($T_\Lambda$ ($\Lambda \in P$)).
Let $T_\Lambda = \{t_\Lambda\}$ with $\text{wt}(t_\Lambda) = \Lambda$, $\varepsilon_i(t_\Lambda) = \varphi_i(t_\Lambda) = -\infty$, $\tilde{e}_i t_\Lambda = \tilde{f}_i t_\Lambda = 0$. Tensoring a crystal $B$ with the crystal $T_\Lambda$ has the effect of shifting the weight $\text{wt}$ by $\Lambda$ and leaving the other data fixed.

**Example 4.2** ($B_i$ ($i \in I$)). $B_i = \{b_i(n); n \in \mathbb{Z}\}$ with $\text{wt}(b_i(n)) = n\alpha_i$,
\[
\begin{align*}
\varepsilon_i(b_i(n)) &= \begin{cases} 
- n & \text{if } i = j \\
- \infty & \text{if } j \neq i, 
\end{cases} \quad \varphi_i(b_i(n)) &= \begin{cases} 
 n & \text{if } i = j \\
-\infty & \text{if } j \neq i, 
\end{cases} \\
\tilde{e}_i b_i(n) &= \begin{cases} 
b_i(n+1) & \text{if } i = j \\
0 & \text{if } j \neq i, 
\end{cases} \quad \tilde{f}_i b_i(n) &= \begin{cases} 
b_i(n-1) & \text{if } i = j \\
0 & \text{if } j \neq i. 
\end{cases}
\end{align*}
\] (4.10) (4.11)

We write $b_i$ for $b_i(0)$.

### 4.2 Description of $B(\infty)$

$B(\infty)$ is the crystal associated with the crystal graph of $U_q^- (\mathfrak{g})$ where $\mathfrak{g}$ is the Kac-Moody algebra defined from the Cartan data of Section 1.1.1. One can also define $B(\infty)$ as an abstract crystal. As such, it can be characterized by Kashiwara-Saito’s Proposition 4.3 below.

**Proposition 4.3** ([KS97] Proposition 3.2.3). Let $B$ be a crystal and $b_0$ an element of $B$ with weight zero. Assume the following conditions.

(B1) $\text{wt}(B) \subset Q_-$.

(B2) $b_0$ is the unique element of $B$ with weight zero.

(B3) $\varepsilon_i(b_0) = 0$ for every $i \in I$.

(B4) $\varepsilon_i(b) \in \mathbb{Z}$ for any $b \in B$ and $i \in I$. 

(B5) For every \(i \in I\), there exists a strict embedding \(\Psi_i : B \rightarrow B \otimes B_i\).

(B6) \(\Psi_i(B) \subset B \times \{\tilde{f}_i^n b_i; n \geq 0\}\).

(B7) For any \(b \in B\) such that \(b \neq b_0\), there exists \(i\) such that \(\Psi_i(b) = b' \otimes \tilde{f}_i^n b_i\) with \(n > 0\). Then \(B\) is isomorphic to \(B(\infty)\).

5 Module theoretic realizations of certain crystals

5.1 The crystal \(B\)

Let \(B\) denote the set of isomorphism classes of irreducible \(R\)-modules. Let \(0\) denote the zero module.

Let \(M\) be an irreducible \(R(\nu)\)-module, so that \([M] \in B\). By abuse of notation, we identify \(M\) with \([M]\) in the following definitions. Hence, we are defining operators and functions on \(B \sqcup \{0\}\) below.

Recall from Section 2.5 the definitions

\[
\tilde{e}_i M := \text{soc} e_i M \tag{5.1}
\]

\[
\tilde{f}_i M := \text{cosoc Ind}_{\nu_1}^{\nu + i} L(i) \boxtimes M \tag{5.2}
\]

\[
\varepsilon_i(M) := \max\{n \geq 0 \mid \tilde{e}_i^n M \neq 0\} \tag{5.3}
\]

and similarly the \(\vee\)-versions

\[
\tilde{e}_i^\vee M := \sigma(\tilde{e}_i^\vee(M)) \tag{5.4}
\]

\[
\tilde{f}_i^\vee M := \sigma(\tilde{f}_i^\vee(M)) = \text{cosoc Ind}_{\nu_1}^{\nu + i} L(i) \boxtimes M, \tag{5.5}
\]

\[
\varepsilon_i^\vee(M) := \varepsilon_i(\sigma^\vee(M)) = \max\{m \geq 0 \mid (\tilde{e}_i^\vee)^m M \neq 0\}. \tag{5.6}
\]

For \(\nu = \sum_{i \in I} \nu_i \alpha_i\), \(i \in I\) and \(M \in R(\nu)\)-mod set

\[
\text{wt}(M) = -\nu, \quad \text{wt}_i(M) = \langle h_i, \text{wt}(M) \rangle. \tag{5.7}
\]

Set

\[
\varphi_i(M) = \varepsilon_i(M) + \langle h_i, \text{wt}(M) \rangle. \tag{5.8}
\]

Proposition 5.1. The tuple \((B, \varepsilon_i, \varphi_i, \tilde{e}_i, \tilde{f}_i, \text{wt})\) defines a crystal.

Proof. (C1) is the definition of \(\varphi_i\). (C2)–(C4) was shown in \([KL09]\), see Section 2.5.1. Property (C5) is vacuous as \(\varphi_i(b)\) is always finite for \(b \in B\).

We write \(1 \in B\) for the class of the trivial \(R(\nu)\)-module where \(\nu = 0\) and \(|\nu| = 0\).

One of the main theorems of this paper is Theorem \([7.4]\) that identifies the crystal \(B\) as \(B(\infty)\). However we need the many auxiliary results that follow before we can prove this.
5.2 The crystal $\mathcal{B} \otimes T_\Lambda$

Let $M$ be an irreducible $R(\nu)$-module, so $M \otimes t_\Lambda \in \mathcal{B} \otimes T_\Lambda$. Then
\[
\begin{align*}
\epsilon_i(M \otimes t_\Lambda) &= \epsilon_i(M), \\
\varphi_i(M \otimes t_\Lambda) &= \varphi_i(M) + \lambda_i, \\
\bar{e}_i(M \otimes t_\Lambda) &= \bar{e}_iM \otimes t_\Lambda, \\
\bar{f}_i(M \otimes t_\Lambda) &= \bar{f}_iM \otimes t_\Lambda, \\
wt(M \otimes t_\Lambda) &= -\nu + \Lambda.
\end{align*}
\]

5.3 The crystal $\mathcal{B}^\Lambda$

Let $\mathcal{B}^\Lambda$ denote the set of isomorphism classes of irreducible $R^\Lambda$-modules. As in the previous section, by abuse of notation we write $M$ for $[M]$ below. Define
\[
\begin{align*}
\bar{e}_i^\Lambda : \mathcal{B}^\Lambda &\rightarrow \mathcal{B}^\Lambda \sqcup \{0\} \\
\mathcal{M} &\mapsto \text{pr}_\Lambda \circ \bar{e}_i \circ \text{infl}_\Lambda \mathcal{M} \\
\bar{f}_i^\Lambda : \mathcal{B}^\Lambda &\rightarrow \mathcal{B}^\Lambda \sqcup \{0\} \\
\mathcal{M} &\mapsto \text{pr}_\Lambda \circ \bar{f}_i \circ \text{infl}_\Lambda \mathcal{M} \\
\varepsilon_i^\Lambda : \mathcal{B}^\Lambda &\rightarrow \mathbb{Z} \sqcup \{-\infty\} \\
\mathcal{M} &\mapsto \varepsilon_i(\text{infl}_\Lambda \mathcal{M}) \\
\varphi_i^\Lambda : \mathcal{B}^\Lambda &\rightarrow \mathbb{Z} \sqcup \{-\infty\} \\
\mathcal{M} &\mapsto \max \{ k \in \mathbb{Z} \mid \text{pr}_\Lambda \circ \bar{f}_i^k \circ \text{infl}_\Lambda \mathcal{M} \neq 0 \} \\
\text{wt}^\Lambda : \mathcal{B}^\Lambda &\rightarrow P \\
\mathcal{M} &\mapsto -\nu + \Lambda. 
\end{align*}
\]

Note $\varepsilon_i^\Lambda(\mathcal{M}) = \max \{ k \in \mathbb{Z} \mid (\bar{e}_i^\Lambda)^k \mathcal{M} \neq 0 \}$, and $0 \leq \varphi_i^\Lambda(\mathcal{M}) < \infty$.

It is true, but not at all obvious, that with this definition $\varphi_i^\Lambda(\mathcal{M}) = \varepsilon_i^\Lambda(\mathcal{M}) + \langle h_i, \text{wt}^\Lambda \mathcal{M} \rangle$; see Corollary 6.21. The proof that the data $(\mathcal{B}^\Lambda, \varepsilon_i^\Lambda, \varphi_i^\Lambda, \bar{e}_i^\Lambda, \bar{f}_i^\Lambda, \text{wt}^\Lambda)$ defines a crystal is delayed until Section 7.

On the level of sets define a function
\[
\Upsilon : \mathcal{B}^\Lambda \rightarrow \mathcal{B} \otimes T_\Lambda \\
\mathcal{M} \mapsto \text{infl}_\Lambda \mathcal{M} \otimes t_\Lambda. 
\]

The function $\Upsilon$ is clearly injective and satisfies
\[
\begin{align*}
\varepsilon_i^\Lambda(\mathcal{M}) &= \varepsilon_i(\Upsilon \mathcal{M}), \\
\Upsilon \bar{e}_i^\Lambda \mathcal{M} &= \bar{e}_i \Upsilon \mathcal{M}, \\
\Upsilon \bar{f}_i^\Lambda \mathcal{M} &= \begin{cases} 
\bar{f}_i \Upsilon \mathcal{M} & \bar{f}_i^\Lambda \mathcal{M} \neq 0 \\
0 & \bar{f}_i^\Lambda \mathcal{M} = 0
\end{cases}, \\
\text{wt}^\Lambda(\mathcal{M}) &= \text{wt}(\Upsilon \mathcal{M}).
\end{align*}
\]

Later we will see the relationship between $\varphi_i^\Lambda(\mathcal{M})$ and $\varphi_i(\text{infl}_\Lambda \mathcal{M})$. Once this relationship is in place (see Corollary 6.21) it will imply $\Upsilon$ is an embedding of crystals and in particular that $\mathcal{B}^\Lambda$ is a crystal. In Section 7 we show that $\mathcal{B} \cong B(\infty)$ which then identifies $\mathcal{B}^\Lambda$ as the highest weight crystal $B(\Lambda)$. 

24
6 Understanding R(\nu)-modules and the crystal data of B

This section contains an in depth study of simple R(\nu)-modules and the functor \bar{f}_{i}. In particular, we measure how the quantities \epsilon_{ij}^{\nu}, \epsilon_{i}, \varphi_{i}^{\nu} change with the application of \bar{f}_{j}.

Throughout this section we assume \epsilon \neq i and set \alpha = (h_{i}, \alpha_{j}).

6.1 Jump

Given an irreducible module \nu, pr_{A} \bar{f}_{i} \nu is either irreducible or zero. In the following subsection, we measure exactly when the latter occurs. More specifically, we compare \epsilon_{i}^{\nu}(\nu) to \epsilon_{i}^{\nu}(\bar{f}_{i} \nu) and compute when the latter quantity “jumps” by +1. In this case, we show \bar{f}_{i} \nu \cong \bar{f}_{i}^{\nu} \nu. Understanding exactly when this jump occurs will be a key ingredient in constructing the strict embedding of crystals in Section 7.1.

One very useful byproduct of understanding co-induction is that for irreducible \nu if we know \bar{f}_{i} \nu \cong \bar{f}_{i}^{\nu} \nu then we can easily conclude \bar{f}_{i}^{m} \nu \cong \text{Ind} L(i^{m}) \otimes \nu, not just for \epsilon = 1, but for all \epsilon \geq 1, and in particular that the latter module is irreducible. We will prove this in Proposition 6.2 below. While for the main results of this paper, it suffices to understand exactly when \bar{f}_{i} \nu \cong \bar{f}_{i}^{\nu} \nu, we found it worthwhile to include Section 7.1 precisely for the sake of a deeper understanding of Ind L(i).

The following proposition is a consequence of Theorem 2.2 and the properties listed in Section 2.5.1.

**Proposition 6.1.** Let \nu be an irreducible R(\nu)-module. Let \epsilon \geq 1. Up to grading shift,

1. \bar{f}_{i}^{m} \nu \cong \text{soc} \text{coInd} L(i^{m}) \cong \text{Ind} L(i^{m}) \otimes \nu.

2. \bar{f}_{i}^{\nu} \nu \cong \text{soc} \text{coInd} L(i^{m}) \otimes \nu \cong \text{Ind} M \otimes L(i^{m}).

**Proof.** Let \epsilon = \epsilon(M) and \nu = \epsilon \nu. Recall from Section 2.5.1

\text{Res}_{\nu} \nu = N \otimes L(i^{m}).

We thus have a nonzero map \text{Res}_{\nu} \nu : M \rightarrow N \otimes L(i^{m}), hence a nonzero and thus injective map

M \rightarrow \text{coInd} N \otimes L(i^{m}).

Repeating the standard arguments from [GV01, KL09] we see \nu \cong \text{soc} \text{coInd} N \otimes L(i^{m}) and that all other composition factors have \epsilon \strictly smaller that \epsilon. Likewise we have \bar{f}_{i}^{m} \nu \cong \text{soc} \text{coInd} N \otimes L(i^{m+n}) and deduce statement (1), using Theorem 2.2. The proof of (2) is similar.

It is necessary to understand how \epsilon_{i}^{\nu} changes with application of \bar{f}_{j}.

**Proposition 6.2.** Let \nu be an irreducible R(\nu)-module.

i) For any \epsilon \in I, either \epsilon_{i}^{\nu}(\bar{f}_{i} \nu) = \epsilon_{i}^{\nu}(\nu) or \epsilon_{i}^{\nu}(\nu) + 1.

ii) For any \epsilon, \epsilon' \in I with \epsilon \neq \epsilon', we have \epsilon_{i}^{\nu}(\bar{f}_{j} \nu) = \epsilon_{i}^{\nu}(\nu) and \epsilon_{i}(\bar{f}_{j} \nu) = \epsilon_{i}(\nu).
We warn the reader that with this extended definition of $\phi$ negative values but can be equal to $-\infty$ e $\phi$. In the case $i = j$ we then get $\varepsilon_i^\nu(M) \leq \varepsilon_i^\nu(\tilde{f}_j M) \leq \varepsilon_i^\nu(M) + 1$ and in the case $i \neq j$ $\varepsilon_i^\nu(M) \leq \varepsilon_i^\nu(\tilde{f}_j M) \leq \varepsilon_i^\nu(M)$. Applying the automorphism $\sigma$ in the case $i \neq j$ also yields the symmetric statement $\varepsilon_i(\tilde{f}_j^\nu M) = \varepsilon_i(M)$. \hfill \Box

**Definition 6.3.** Let $M$ be an irreducible $R(\nu)$-module and let $\Lambda \in P^+$. Define

$$\varphi_i^\Lambda(M) = \max\{k \in \mathbb{Z} \mid \text{pr}_\Lambda \tilde{f}_i^k M \neq 0\}. \quad (6.4)$$

where we take the convention that $\tilde{f}_i^k = \varepsilon_i^{-k}$ when $k < 0$.

Note that $\text{pr}_\Lambda M \neq 0$ if and only if $\varphi_i^\Lambda(M) \geq 0$ for all $i \in I$ by Remark 2.4 or even for a single $i \in I$ by Proposition 6.2. Hence, by allowing $\varphi_i^\Lambda$ to take negative values, we can use $\varphi_i^\Lambda$ to detect which irreducible $R(\nu)$-modules are in fact $R^\Lambda(\nu)$-modules. Thus when $\varphi_i^\Lambda(M) \geq 0$ it agrees with $\varphi_i^\Lambda(\text{pr}_\Lambda M)$ as defined in Section 5.3 which is manifestly nonnegative. By abuse of notation we call both functions $\varphi_i^\Lambda$.

Observe that

$$\varphi_i^\Lambda(\tilde{f}_i M) = \varphi_i^\Lambda(M) - 1. \quad (6.5)$$

We warn the reader that with this extended definition of $\varphi_i^\Lambda$ on $G_0(R)$, it not only takes negative values but can be equal to $-\infty$. For example, take $\Lambda = \Lambda_i$, and let $j \neq i$. Then $\tilde{e}_i L(j) = 0$ and we see $\text{pr}_\Lambda \tilde{f}_i^k L(j) = 0$ for all $k \in \mathbb{Z}$ by Proposition 6.2. Hence $\varphi_i^\Lambda(L(j)) = -\infty$. However, this is no call for alarm, as by Remark 2.4 we can always find a larger $\Lambda$ so that $\text{pr}_\Lambda M \neq 0$ for any given $M$.

**Definition 6.4.** Let $M$ be a simple $R(\nu)$-module and let $i \in I$. Then

$$\text{jump}_i(M) := \max\{J \geq 0 \mid \varepsilon_i^\nu(M) = \varepsilon_i^\nu(\tilde{f}_i^J M)\}. \quad (6.6)$$

In the following Lemma we collect a long list of useful characterizations of when $\text{jump}_i(M) = 0$. We find it convenient to be overly thorough below and furthermore to give this lemma the name “Jump Lemma” because we use it repeatedly throughout the paper.

We remind the reader that the isomorphisms below are homogeneous but not necessarily degree preserving.

**Lemma 6.5** (Jump Lemma). Let $M$ be irreducible. The following are equivalent:

1) $\text{jump}_i(M) = 0$

2) $\tilde{f}_i M \cong \tilde{f}_i^\nu M$

3) $\tilde{f}_i^m M \cong (\tilde{f}_i^\nu)^m M$ for all $m \geq 1$

4) $\text{Ind} M \boxtimes L(i) \cong \text{Ind} L(i) \boxtimes M$

5) $\text{Ind} M \boxtimes L(i^m) \cong \text{Ind} L(i^m) \boxtimes M$ for all $m \geq 1$
\[ \text{JUMP} \]

6) \( \widetilde{f}_i M \cong \text{Ind} M \otimes L(i) \)

6') \( \widetilde{f}_i^\gamma M \cong \text{Ind}(i) \otimes M \)

7) \( \text{Ind} M \otimes L(i) \) is irreducible

7') \( \text{Ind}(i) \otimes M \) is irreducible

8) \( \text{Ind} M \otimes L(i^m) \) is irreducible for all \( m \geq 1 \)

8') \( \text{Ind}(i^m) \otimes M \) is irreducible for all \( m \geq 1 \)

9) \( \varepsilon_i^\gamma(\widetilde{f}_i M) = \varepsilon_i^\gamma(M) + 1 \)

9') \( \varepsilon_i(\widetilde{f}_i^\gamma M) = \varepsilon_i(M) + 1 \)

10) \( \text{jump}_\nu(\widetilde{f}_i^m M) = 0 \) for all \( m \geq 0 \)

11) \( \varepsilon_i(\widetilde{f}_i^m M) = \varepsilon_i^\gamma(M) + m \) for all \( m \geq 1 \)

**Proof.** Pairs of “symmetric” conditions labelled by \( X \) and \( X' \) are clearly equivalent to each other by applying the automorphism \( \sigma \), except for \( (9) \Leftrightarrow (9)' \) which is slightly less obvious. We will show \( (2) \Leftrightarrow (9) \) which then gives \( (2) \Leftrightarrow (9)' \) by \( \sigma \)-symmetry.

By Proposition 6.2 we have \( \varepsilon_i^\gamma(X) \leq \varepsilon_i^\gamma(X') \leq \varepsilon_i^\gamma(X) + 1 \). This yields \( (11) \Leftrightarrow (9) \). Suppose \( (9) \) holds, i.e. \( \varepsilon_i(\widetilde{f}_i M) = \varepsilon_i^\gamma(M) + 1 = \varepsilon_i(\widetilde{f}_i^\gamma M) \). By the Shuffle Lemma,

\[ \text{ch}(\text{Ind} M \otimes L(i)) \mid_{q=1} = \text{ch}(\text{Ind}(i) \otimes M) \mid_{q=1}, \tag{6.7} \]

so by the injectivity of the character map and the discussion of Section 2.7, they have same composition factors. But \( \widetilde{f}_i M \) is the unique composition factor of \( \text{Ind}(i) \otimes M \) with largest \( \varepsilon_i^\gamma \), forcing \( \widetilde{f}_i M \cong \widetilde{f}_i^\gamma M \) up to grading shift, which yields \( (2) \). The converse of \( (2) \Rightarrow (9) \) is obvious. So we have \( (2) \Leftrightarrow (9) \) and by \( \sigma \)-symmetry also \( (2) \Leftrightarrow (9)' \).

Next suppose \( (2) \), i.e. \( f_i M \cong \widetilde{f}_i^\gamma M \). This implies

\[ \text{cosoc Ind} M \otimes L(i) \cong \text{coInd} L(i) \otimes M \cong \text{soc Ind} M \otimes L(i) \tag{6.8} \]

by Proposition 6.1. Furthermore from Section 2.5.1 \( \widetilde{f}_i M \) is not only the cosocle, but occurs with multiplicity one in \( \text{Ind} M \otimes L(i) \). For it to also be the socle forces \( \text{Ind} M \otimes L(i) \) to be irreducible, yielding \( (7) \). Clearly \( (7) \Leftrightarrow (6) \). Further \( (7) \Rightarrow (4) \) as \( \text{ch}(\text{Ind} M \otimes L(i)) = \text{ch}(\text{Ind}(i) \otimes M) \) at \( q = 1 \).

Given \( (4) \) an inductive argument and transitivity of induction gives \( (5) \), that \( \text{Ind} M \otimes L(i^m) \cong \text{Ind} L(i^m) \otimes M \) for all \( m \geq 1 \). Thus, \( \widetilde{f}_i^m M \cong \text{cosoc Ind} M \otimes L(i^m) \cong \text{cosoc Ind} L(i^m) \otimes M \cong (\widetilde{f}_i^\gamma)^m M \), yielding \( (3) \) and thus \( (11) \) by then evaluating \( \varepsilon_i^\gamma \). That \( (11) \Rightarrow (3) \) is an identical argument to \( (9) \Rightarrow (2) \).

Now suppose \( (3) \) holds. Again by Proposition 6.1

\[ \text{cosoc Ind} M \otimes L(i^m) \cong \text{coInd} L(i^m) \otimes M \cong \text{soc Ind} M \otimes L(i^m) \tag{6.9} \]

so as above \( \text{Ind} M \otimes L(i^m) \) is irreducible, yielding \( (5) \), and hence it is isomorphic to \( \widetilde{f}_i^m M \).

It is trivial to check \( (8) \Rightarrow (7) \Rightarrow (4) \Rightarrow (2) \) and \( (6) \Leftrightarrow (6)' \). \( (7) \Leftrightarrow (7)' \). \( (8) \Leftrightarrow (8)' \). Finally, since \( (1) \Leftrightarrow (11) \) we certainly have \( (1) \Leftrightarrow (10) \). This completes the proof.

The following proposition gives alternate characterizations of \( \text{jump}_\nu(M) \). Although we do not prove that all five hold at this time, it is worth stating them all together now.

**Proposition 6.6.** Let \( M \) be a simple \( R(\nu) \)-module and let \( i \in I \). Then the following hold.
i) $\text{jump}_i(M) = \max\{J \geq 0 \mid \varepsilon_i(M) = \varepsilon_i((\tilde{f}_i^\vee)^J M)\}$

ii) $\text{jump}_i(M) = \min\{J \geq 0 \mid \tilde{f}_i(\tilde{f}_i^J M) \cong \tilde{f}_i((\tilde{f}_i^\vee)^J M)\}$

iii) $\text{jump}_i(M) = \min\{J \geq 0 \mid \tilde{f}_i((\tilde{f}_i^\vee)^J M) \cong \tilde{f}_i((\tilde{f}_i^\vee)^J M)\}$

iv) If $\varphi_i^\Lambda(M) > -\infty$, then $\text{jump}_i(M) = \varphi_i^\Lambda(M) + \varepsilon_i^\gamma(M) - \lambda_i$.

v) $\text{jump}_i(M) = \varepsilon_i(M) + \varepsilon_i^\gamma(M) + \text{wt}_i(M)$.

**Proof.** We must delay the proof of (v) until we have proved Theorem 6.12 and consequently Corollary 6.21. We will only prove (iii) and (iv) now as we will need them frequently in the sequel.

The equivalence of (iii) to the definition of $\text{jump}_i$ is $\sigma$-symmetric to the equivalence of (i) $\iff$ (iii), and (iii) is $\sigma$-symmetric to (iii). So once we have (v) which is a $\sigma$-symmetric statement, we will have all (i)–(v) of the proposition.

Since we do not use (i) or (iii) in the rest of this section, we won’t prove them here independently of (v) and in fact to do so would be rather difficult.

Now we prove (ii). Let $J = \text{jump}_1(M)$ and $N = \tilde{f}_1^J M$. Then by the maximality of $J$,

$$\varepsilon_i^\gamma(\tilde{f}_i N) = \varepsilon_i^\gamma(N) + 1 = \varepsilon_i^\gamma(M) + 1.$$ 

By the Jump Lemma 6.5, $\tilde{f}_i N \cong \tilde{f}_i^\vee N$, i.e. $\tilde{f}_i(\tilde{f}_i^J M) \cong \tilde{f}_i(\tilde{f}_i^J M)$. Further, if $0 \leq m < J$ then

$$\varepsilon_i^\gamma(\tilde{f}_i^\vee \tilde{f}_i^m M) = 1 + \varepsilon_i(\tilde{f}_i^m M) = 1 + \varepsilon_i^\gamma(M) > \varepsilon_i^\gamma(M) = \varepsilon_i^\gamma(\tilde{f}_i^{m+1} M)$$

(6.10)

so $\tilde{f}_i^\vee \tilde{f}_i^m M \not\cong \tilde{f}_i \tilde{f}_i^m M$. This yields (ii).

Now we prove (iv). Again let $J = \text{jump}_1(M)$. First, suppose $\varphi_i^\Lambda(M) \geq 0$. Then, as $\text{pr}_A \tilde{f}_i^\varphi(M) \neq 0$, it follows from Proposition 6.2 and Remark 2.1 that $\text{pr}_A M \neq 0$. Hence $\lambda_i \geq \varepsilon_i^\gamma(M) = \varepsilon_i^\gamma(\tilde{f}_i^J M)$. But by (iii) of the Jump Lemma $\varepsilon_i^\gamma(\tilde{f}_i^J M) = \varepsilon_i^\gamma(M) + m$ for all $m \geq 0$.

Set $m = \lambda_i - \varepsilon_i^\gamma(M)$. Then by the maximality of $J$, $\varepsilon_i^\gamma(\tilde{f}_i^{J+m} M) = \lambda_i$ but $\varepsilon_i^\gamma(\tilde{f}_i^{J+m+1} M) = \lambda_i + 1$. And by Proposition 6.2 $\varepsilon_i^\gamma(\tilde{f}_i^{J+m} M) = \varepsilon_i^\gamma(M) \leq \lambda_j$. In other words $\text{pr}_A \tilde{f}_i^{J+m+1} M \neq 0$ but $\text{pr}_A \tilde{f}_i^{J+m+1} M = 0$, so by definition $\varphi_i^\Lambda(M) = J + m = \text{jump}_i(M) + \lambda_i - \varepsilon_i^\gamma(M)$. Equivalently $\text{jump}_i(M) - \varphi_i^\Lambda(M) + \varepsilon_i^\gamma(M) - \lambda_i$.

Second, if $-\infty < \varphi_i^\Lambda(M) < 0$, let $k = -\varphi_i^\Lambda(M)$. Note $\varepsilon_i^\gamma(\tilde{e}_i^k M) = \lambda_i$ but $\varepsilon_i \varepsilon_i^{k-1} M = \lambda_i + 1$ so that $\text{jump}_i(\tilde{e}_i^{k} M) = 0$ and hence $\text{jump}_i(M) = 0$ too, by characterization (iii) of the Jump Lemma. As before, $\varepsilon_i^\gamma(M) = \varepsilon_i^\gamma(\tilde{f}_i \tilde{e}_i^{k} M) = \varepsilon_i^\gamma(\tilde{e}_i^{k} M) + k = \lambda_i - \varphi_i^\Lambda(M)$. So again $\text{jump}_i(M) = 0 = \varphi_i^\Lambda(M) + \varepsilon_i^\gamma(M) - \lambda_i$.

It is clear from the Proposition that

$$\text{jump}_i(\tilde{f}_i^J M) = \max\{0, \text{jump}_1(M) - 1\} = \text{jump}_i(\tilde{f}_i^\vee M).$$

(6.11)

**Remark 6.7.** Given $\Lambda, \Omega \in P^+$ and irreducible modules $A$ and $B$ with $\text{pr}_A A \neq 0$, $\text{pr}_B A \neq 0$, $\text{pr}_B A \neq 0$, $\text{pr}_B B \neq 0$, then $\varphi_i^\Lambda(A) - \varphi_i^\Omega(B) = \varphi_i^\gamma(A) - \varphi_i^\Omega(B)$ since by Proposition 6.6 (iv) we compute

$$\varphi_i^\Lambda(A) - \varphi_i^\Omega(B) = (\text{jump}_i(A) - \varepsilon_i^\gamma(A) + \lambda_i) - (\text{jump}_i(B) - \varepsilon_i^\gamma(B) + \lambda_i)$$

(6.12)

$$= \text{jump}_i(A) - \text{jump}_i(B) + \varepsilon_i^\gamma(B) - \varepsilon_i^\gamma(A)$$

(6.13)

$$= \varepsilon_i^\gamma(A) - \varepsilon_i^\gamma(B).$$

(6.14)
6.2 Serre relations

In this section, we present certain (minimal) relations that hold among the operators $e_i$ on $G_0(R)$. These are the quantum Serre relations [6.16]. We refer the reader to [KL08a], where they prove similar relations (the vanishing of alternating sums in $K_0(R)$) hold on a certain family of projective modules in their Corollary 7. Then by the obvious generalization to the symmetrizable case of Corollary 2.15 of [KL09] we have

$$
\sum_{r=0}^{a+1} (-1)^r e_i^{(a+1-r)} e_j e_i^{(r)} [M] = 0 \quad (6.15)
$$

for all $M \in R(\nu)-\text{mod}$ with $|\nu| = a + 1$, and hence for all $[M] \in G_0(R)$, showing the operator

$$
\sum_{r=0}^{a+1} (-1)^r e_i^{(a+1-r)} e_j e_i^{(r)} = 0. \quad (6.16)
$$

Recall the divided powers $e_i^{(r)}$ are given by $e_i^{(r)} [M] = \frac{1}{[r]_i} [e_i^r M]$.

Furthermore, when $c \leq a$ the operator

$$
\sum_{r=0}^{c} (-1)^r e_i^{(c-r)} e_j e_i^{(r)} \quad (6.17)
$$

is never the zero operator on $G_0(R)$ by the quantum Gabber-Kac Theorem [Lus93] and the work of [KL09], which essentially computes the kernel of the map from the free algebra on the generators $e_i$ to $G_0(R)$, see Remark 1.2.

In Section 6.3.1 below, we give an alternate proof that the quantum Serre relation (6.16) holds by examining the structure of all simple $R((a+1)i+j)$-modules. We further construct simple $R(ci+j)$-modules that are witness to the nonvanishing of (6.17) when $c \leq a$. In the following remark, we give a sample argument of how understanding the simple $R(\nu)$-modules for a fixed $\nu$ gives a relation among the operators $e_i$ on $G_0(R)$. Although we only give it in detail for a degree 2 relation among the $e_i$, it can be easily extended to higher degree relations.

**Remark 6.8.** Suppose we have explicitly constructed all simple $R(i+j)$-modules $M$, and have verified $(e_j e_i - e_j e_i)[M] = 0$ for all such $M$. (We know this is the case whenever $(i,j) = 0$.) We will call this a degree 2 relation in the $e_i$‘s for obvious reasons. We easily see the operator $e_j e_i - e_j e_i$ is zero on $G_0(R(\mu)-\text{mod})$ not just for $\mu = i+j$ but for any $\nu$ with $|\nu| = 0, 1, 2$. Now consider arbitrary $\nu$ with $|\nu| > 2$. Let $M$ be any finite dimensional $R(\nu)$-module. We can write $[\text{Res}_{\nu-\mu, \mu} M] = \sum_h [A_h \boxtimes B_h]$ for some simple $R(\mu)$-modules $B_h$ with $|\mu| = 2$, or the restriction is zero. Then

$$
(e_j e_i - e_j e_i)[M] = \sum_{\mu : |\mu| = 2} \sum_h [A_h \boxtimes (e_j e_i - e_j e_i) B_h] \quad (6.18)
$$

$$
= \sum \sum [A_h \boxtimes 0] = 0. \quad (6.19)
$$

Hence $e_j e_i - e_j e_i$ is zero as an operator on $G_0(R)$. However, this is a relation of the form (6.17) with $c = 0$. By the discussion above on the minimality of the quantum Serre relation, this forces $a_{ij} = 0$. Similarly, if one shows the expression (6.16) in the quantum Serre relation vanishes on all irreducible $R((a+1)i+j)$-modules, the same argument shows the relation holds on all $G_0(R)$ and that $a_{ij} \leq a$. 

29
6.3 The Structure Theorems for simple $R(ci + j)$-modules

In this section we describe the structure of all simple $R(ci + j)$-modules. We will henceforth refer to Theorems 6.9, 6.10 as the Structure Theorems for simple $R(ci + j)$-modules. Throughout this section we assume $j \neq i$ and set $a = a_{ij} = -\langle h_i, \alpha_j \rangle$.

In the theorems below we introduce the notation $L(i^c - n ji^n)$ and $L(n) \overset{\text{def}}{=} L(i^c - n ji^n)$ for the irreducible $R(ci + j)$-modules (up to grading shift) when $c \leq a$. They are characterized by $\varepsilon_i(L(i^c - n ji^n)) = n$.

Theorem 6.9. Let $c \leq a$ and let $\nu = ci + j$. Up to isomorphism and grading shift, there exists a unique irreducible $R(\nu)$-module denoted $L(i^c - n ji^n)$ with

$$\varepsilon_i(L(i^c - n ji^n)) = n$$

for each $n$ with $0 \leq n \leq c$. Furthermore,

$$\varepsilon_\nu(L(i^c - n ji^n)) = c - n$$

and

$$\text{ch}(L(i^c - n ji^n)) = [c - n]_i! [n]_i! i^c - n ji^n.$$  

In particular, in the Grothendieck group $e_j e_i - e_i e_j[M] = 0$ unless $s = n$.

Proof. The proof is by induction on $c$. The case $c = 0$ is obvious; up to isomorphism and grading shift there exists a unique irreducible $R(j)$-module $L(j)$ which obviously satisfies (6.20)–(6.22). In the following, isomorphisms are allowed to be homogeneous but not necessarily degree preserving.

The case $c = 1$ is also straightforward. Since $c \leq a$, and so $a \neq 0$, we compute $\text{Ind} L(i) \boxtimes L(j)$ is reducible, but has irreducible cosocle. Let

$$\mathcal{L}(ij) = \text{cosoc } \text{Ind} L(i) \boxtimes L(j)$$

and $\mathcal{L}(ji) = \text{cosoc } \text{Ind} L(j) \boxtimes L(i)$.

Note each of the above modules is one-dimensional and satisfies (6.20)–(6.22). Observe if (6.20) did not hold for either module, then by the Jump Lemma 6.5.

$$\text{Ind} L(i) \boxtimes L(j) \cong \text{Ind} L(j) \boxtimes L(i)$$

and this module would be irreducible. Hence for all $R(i + j)$-modules $M$ we would have

$$(e_j e_i - e_i e_j)[M] = 0$$

and in fact this relation would then hold for any $\nu$ and any irreducible $R(\nu)$-module $M$ via Remark 6.8. But by (6.17) this would imply $a = 0$, a contradiction.

Now assume the theorem holds for some fixed $c \leq a$ and we will show it also holds for $c + 1$ so long as $c + 1 \leq a$. Let $N$ be an irreducible $R((c + 1)i + j)$-module with $\varepsilon_i(N) = n$.

Suppose $n > 0$. If in fact $n = 0$ consider instead $\nu = \varepsilon_\nu N$ which cannot also be $0$ and perform the following argument applying the automorphism $\sigma$ everywhere. Observe any
other module $N'$ such that $\varepsilon_i(N') = n$ has $\tilde{c}_i N' \cong \tilde{c}_i N$, forcing $N' \cong N$, which gives us the uniqueness. Note $\tilde{c}_i N$ is an $R(ci + j)$-module with $\varepsilon_i(\tilde{c}_i N) = n - 1$ so by the inductive hypothesis $\tilde{c}_i N = \mathcal{L}(i^{c+1-n}ji^{n-1})$. We have a surjection (up to grading shift)

$$\text{Ind} \mathcal{L}(i^{c+1-n}ji^{n-1}) \otimes L(i) \rightarrow N. \quad (6.27)$$

Since $N = \text{cosoc} \ \text{Ind} \mathcal{L}(i^{c+1-n}ji^{n-1}) \otimes L(i)$, by Frobenius reciprocity, the Shuffle Lemma, and the fact that $L(i^n)$ is irreducible with character $[m]_i^m$, either we have

$$\text{ch}(N) = [c + 1 - n]_i^{1}[n]_i^1i^{c+1-n}ji^n \quad (6.28)$$

or

$$\text{ch}(N) = [c + 1 - n]_i^{1}[n]_i^1i^{c+1-n}ji^n + q^{-\langle \alpha_i, \alpha_j \rangle} [c + 2 - n]_i^{1}[n - 1]_i^{1}i^{c+2-n}ji^{n-1} \quad (6.29)$$

$$= \text{ch(Ind} \mathcal{L}(i^{c+1-n}ji^{n-1}) \otimes L(i)). \quad (6.30)$$

In the former case, $N$ satisfies (6.22) and of course also (6.21). In the latter case, by the injectivity of the character map, we must have isomorphisms $N \cong \text{Ind} \mathcal{L}(i^{c+1-n}ji^{n-1}) \otimes L(i)$ and in fact, up to grading shift,

$$\text{Ind} \mathcal{L}(i^{c+1-n}ji^{n-1}) \otimes L(i) \cong \text{Ind} L(i) \otimes \mathcal{L}(i^{c+1-n}ji^{n-1}). \quad (6.31)$$

Next we will show that if (6.31) holds for this $n$, then it holds for all $1 \leq n \leq c$.

Let $M = \text{cosoc} \ \text{Ind} L(i) \otimes \mathcal{L}(i^{-n}ji^n)$ which is irreducible. By the Shuffle Lemma, either $\varepsilon_i(M) = n$ or $\varepsilon_i(M) = n + 1$. If $\varepsilon_i(M) = n$, then by uniqueness part of the inductive hypothesis $\tilde{c}_i M \cong \tilde{c}_i N$ and so $M \cong N$. But this is impossible as $i^{c+2-n}ji^{n-1}$ can never be a constituent of $\text{ch}(M)$. So we must have $\varepsilon_i(M) = n + 1$. Repeating the same analysis of characters as above we must have

$$M \cong \text{Ind} L(i) \otimes \mathcal{L}(i^{-n}ji^n) \cong \text{Ind} \mathcal{L}(i^{c-n}ji^n) \otimes L(i). \quad (6.32)$$

Continuing in this manner, we deduce

$$\text{Ind} L(i) \otimes \mathcal{L}(i^{-g}ji^g) \cong \text{Ind} \mathcal{L}(i^{c-n}ji^n) \otimes L(i) \quad (6.33)$$

for all $n - 1 \leq g \leq c$.

We may repeat the same argument applying the automorphism $\sigma$ everywhere. In other words consider $\varepsilon_i^\gamma(N) = c + 2 - n$ and start with

$$M' = \text{cosoc} \ \text{Ind} \mathcal{L}(i^{c+2-n}ji^{n-2}) \otimes L(i) \quad (6.34)$$

which will force $\varepsilon_i^\gamma(M') = c + 3 - n$ and

$$\text{Ind} \mathcal{L}(i^{c+2-n}ji^{n-2}) \otimes L(i) \cong \text{Ind} L(i) \otimes \mathcal{L}(i^{c+2-n}ji^{n-2}). \quad (6.35)$$

Continuing as before yields isomorphisms (6.33) for $n - 1 > g \geq 0$, in other words for all $g$.

Under the original assumption that the $R((c + 1)i + j)$-module $N$ does not satisfy (6.22), we have shown that every irreducible $R((c + 1)i + j)$-module $A$ satisfies

$$A \cong \text{Ind} L(i) \otimes B \cong \text{Ind} B \otimes L(i) \quad (6.36)$$

31
for some irreducible \( R(ci + j) \)-module \( B \), and furthermore we have computed \( \text{ch}(A) \).

On closer examination of these characters, we see

\[
\sum_{s=0}^{c+1} (-1)^s e_i^{(c+1-s)} e_j e_i^{(s)} [A] = 0 \tag{6.37}
\]

for all such \( A \). But then an argument similar to that in Remark 6.8 shows

\[
\sum_{s=0}^{c+1} (-1)^s e_i^{(c+1-s)} e_j e_i^{(s)} [C] = 0 \tag{6.38}
\]

for all irreducible \( R(\nu) \)-modules \( C \) for any \( \nu \in \mathbb{N}[I] \). So by (6.17), (6.16) we would get \( a \leq c \), contradicting \( c + 1 \leq a \).

So it must be that all irreducible \( R((c + 1)i + j) \)-modules satisfy (6.20), (6.21), and (6.22).

In the previous theorem we introduced the notation \( \mathcal{L}(i^{c-n}ji^n) \) for the unique (up to isomorphism and grading shift) simple \( R(ci+j) \)-module with \( \varepsilon_i = n \) when \( c \leq a \). Theorem 6.10 below extends this uniqueness to \( c \geq a \). Recall that in the special case that \( c = a \), we denote \( \mathcal{L}(n) = \mathcal{L}(i^n) \).

The following theorem motivates why we distinguish the special case \( c = a \).

**Theorem 6.10.** Let \( 0 \leq n \leq a \).

i) The module

\[
\text{Ind } L(i^n) \boxtimes \mathcal{L}(n) \cong \text{Ind } \mathcal{L}(n) \boxtimes L(i^n) \tag{6.39}
\]

is irreducible for all \( m \geq 0 \).

ii) Let \( c \geq a \). Let \( N \) be an irreducible \( R(ci+j) \)-module with \( \varepsilon_i(N) = n \). Then \( c - a \leq n \leq c \) and up to grading shift

\[
N \cong \text{Ind } \mathcal{L}(n - (c - a)) \boxtimes L(i^{c-a}). \tag{6.40}
\]

**Proof.** We first prove (6.39) for \( m = 1 \), from which it will follow for all \( m \) by the Jump Lemma [6.5]. Let \( M = \mathcal{L}(n) = \text{cosoc } \text{Ind } \mathcal{L}(n) \boxtimes L(i) \), which is irreducible. Note \( \varepsilon_i(M) = n + 1 \) and by the Shuffle Lemma

\[
e_i^{(a-n)} e_j e_i^{(n+1)} [M] \neq 0 \tag{6.41}
\]

but

\[
e_i^{(a+1-s)} e_j e_i^{(s)} [M] = 0 \tag{6.42}
\]

unless \( s = n + 1 \) or \( s = n \). But the Serre relations (6.16) imply the following operator is identically zero:

\[
\sum_{s=0}^{a+1} (-1)^s e_i^{(a+1-s)} e_j e_i^{(s)} = 0. \tag{6.43}
\]
In particular,\[0 = \sum_{s=0}^{a+1} (-1)^s e_i^{(a+1-s)} e_j e_i^{(s)}[M],\]
from which we conclude, by (6.44), that
\[e_i^{(a+1-n)} e_j e_i^{(n)}[M] \neq 0.\] (6.45)
This implies
\[a - n + 1 = e_i^\vee M = e_i^\vee (\tilde{f}_i L(n)) = e_i^\vee (L(n)) + 1\] (6.46)
so that by the Jump Lemma \(\tilde{f}_i L(n) \cong f_i^\vee L(n),\) and consequently part 1 of the theorem also holds for all \(m \geq 1.\) (The case \(m = 0\) is vacuously true.)

For part 2, we induct on \(c \geq a,\) the case \(c = a\) following directly from Theorem 6.9. Now assume the statement for general \(c > a\) and consider an irreducible \(R((c+1)i + j)\)-module \(N\) such that \(e_i(N) = n.\) If \(n = 0,\) then clearly \(e_i^{(c+1)} e_j[N] \neq 0\) so also \(e_i^{(a+1)} e_j[N] \neq 0,\) which by the Serre relations (6.16) implies there exists an \(n' \neq 0\) with \(e_i^{(a+1-n')} e_j e_i^{(n')}[N] \neq 0.\) But then \(e_i(N) \geq n' > 0,\) which is a contradiction.

Let \(M \cong \tilde{c}_i N \neq 0,\) so that \(e_i(M) = n - 1\) and by the inductive hypothesis
\[M \cong \text{Ind } L(n - 1 - (c - a)) \boxtimes L(i^{c-a}).\]
Hence, by part 1 and the Jump Lemma
\[N \cong \tilde{f}_i M \cong \text{Ind } L(n - ((c + 1) - a)) \boxtimes L(i^{c+1-a}).\] (6.47)
Consequently \(n \geq c+1-a.\) As \(N\) is an irreducible \(R((c+1)i+j)\)-module, clearly \(c+1 \geq n.\)

Observe that from Theorems 6.9, 6.10 and the Shuffle Lemma, we have computed the character (up to grading shift) of all irreducible \(R(ci + j)\)-modules.

### 6.3.1 A generators and relations proof

In this section, we give alternative proofs of the Structure Theorems 6.9 and 6.10 using the description of \(R(\nu)\) via generators and relations. In particular, we do not use the Serre relations (6.16) and in fact one could instead deduce that the Serre relations hold from these theorems.

We first set up some useful notation. For this section let
\[i(b,c) = \begin{array}{cccccc} \hline i & j & i & j & \cdots & i \\ \hline b & b & b & \cdots & b \\ c & c & c & \cdots & c \\ \hline \end{array}\]
Let \(\{u_r \mid 1 \leq r \leq m!\}\) be a (weight) basis of \(L(i^m),\) \(\{y_s \mid 1 \leq s \leq n!\}\) be a basis of \(L(i^n),\) and \(\{\nu\}\) be a basis of \(L(j).\) Recall the following fact about the irreducible module \(L(i^m).\) For any \(u \in L(i^m)\)
\[x_k^u u = 0,\] (6.48)
for all \( k \geq m \), and \( 1 \leq r \leq m \). Further if \( u \neq 0 \) then \( L(i^m) = R(mi)u \), and \( 1_j u = 0 \) if \( j \neq i^m \). Also there exists \( \tilde{u} \in L(i^m) \) such that \( x_r^{m-1}\tilde{u} \neq 0 \) for all \( r \). (We note that it is from these properties we may deduce Remark 2.4.)

The induced module \( \text{Ind} L(i^m) \otimes L(j) \otimes L(i^n) \) has a weight basis

\[
B = \{ \psi_{\tilde{w}} \otimes (v_r \otimes v \otimes y_s) \mid 1 \leq r \leq m!, 1 \leq s \leq n!, \ w = S_{m+1+n}/S_m \times S_1 \times S_n \} \quad (6.49)
\]

as in Remark 2.1.

Proposition 6.11. Let \( K = \text{span}\{ \psi_{\tilde{w}} \otimes (v_r \otimes v \otimes y_s) \in B \mid \ell(w) \neq 0 \} \). Suppose \( c = m+n \leq a \). Then

1. \( K \) is a proper submodule of \( \text{Ind} L(i^m) \otimes L(j) \otimes L(i^n) \).

2. The quotient module \( \text{Ind} L(i^m) \otimes L(j) \otimes L(i^n)/K \) is irreducible with character \([m]_1[n]_1[i^m,j^n] \).

Proof. It suffices to show

\[
\psi_{\tilde{w}} \otimes (u_r \otimes v \otimes y_s) \in K \quad (6.50)
\]

where \( \ell(w) > 0 \) as \( h \) ranges over the generators \( 1_j, x_r, \psi_r \) of \( R(v) \).

Considering the relations in Section 11.1.3 \( h\psi_{\tilde{w}} \otimes (u_r \otimes v \otimes y_s) \) is 0 or a sum of terms of the form \( \psi_{\tilde{w}'} \otimes (u' \otimes v \otimes y' \) with \( \ell(w') \geq \ell(w) - 2 \), so in other words, we reduce to the case \( \ell(w) = 1 \) or \( \ell(w) = 2 \) (or else the terms are obviously in \( K \)). In fact, it is only in considering relation \( (1.29) \) we examine \( \ell(w) = 2 \), and otherwise we examine \( \ell(w) = 1 \).

To make this reduction valid, we first examine the case \( h = x_t \), which in fact does not decrease length at all, showing that when applying relation \( (1.29) \), there is no further reduction of length to the terms \( \psi_{\tilde{w}'} \otimes (u' \otimes v \otimes y' \).

Let \( w \in S_{m+1+n}/S_m \times S_1 \times S_n \) so the diagram for \( \psi_{\tilde{w}} 1_{i(m,n)} \) has no ii-crossings, that is, no crossings \( \psi_{\tilde{w}'} \) between strands that are both labelled by \( i \in I \). Then for \( h = x_t \) we have \( x_t\psi_{\tilde{w}} 1_{i(m,n)} = \psi_{\tilde{w}} x_{w^{-1}(t)}^{-1} 1_{i(m,n)} \) by repeated application of relation \( (1.8) \) and isotopies of diagrams. Algebraically speaking, if \( \tilde{w} = s_r s_{r_2} \cdots s_{r_t} \), then \( i := (s_r w)(i(m,n)) = i(m',n') \) where either \( m' = r \) or \( r - 1 \). In particular \( i_r \neq i_{r+1} \), so that by relation \( (1.30) \) \( x_t \psi_r 1_i = \psi_i x_{s_i(t)} 1_i \), and then by induction we get the statement above. Hence \( (6.50) \) holds for \( h = x_t \) and \( w \) with \( \ell(w) > 0 \).

For \( h = 1_j \), either \( h\psi_{\tilde{w}} 1_{i(m,n)} = 0 \) or \( h\psi_{\tilde{w}} 1_{i(m,n)} = \psi_{\tilde{w}} 1_{i(m,n)} \), so clearly \( (6.50) \) holds.

Next we need only consider the case \( \ell(w) = 2 \), where either \( w = s_{m+1}s_m \) or \( w = s_{m+1+m} \). However, the only cases that are potentially “length-decreasing” by 2 are for \( w = s_{m+1}s_m \) and \( h = \psi_m \), or \( w = s_ms_{m+1} \) and \( h = \psi_{m+1} \), for which we compute

\[
(\psi_m \psi_{m+1} - \psi_{m+1} \psi_m) 1_{i(m,n)} = \sum_{k=0}^{a+1} x^k_m x^{a+1-k}_m 1_{i(m,n)}. \quad (6.51)
\]

By \( (6.48) \)

\[
x^k_m x^{a+1-k}_m (u \otimes v \otimes y) = 1_{i(m,n)} \otimes (x^k_m u) \otimes v \otimes (x^{a+1-k}_m y) = 0 \quad (6.52)
\]

since either \( k \geq m \) or \( a+1-k > a+1-m \geq n \) as we assumed \( m+n \leq a \). This yields

\[
\psi_m \psi_{m+1} \psi_m \otimes (u \otimes v \otimes y) = \psi_{m+1} \psi_m \psi_{m+1} \otimes (u \otimes v \otimes y).
\]
In fact, we also have \( \psi_m \psi_{m-1} \psi_m \otimes (u \otimes v \otimes y) = \psi_{m-1} \psi_m \psi_{m-1} \otimes (u \otimes v \otimes y) \), as for instance \( i(m,n)_{m-1} \neq i(m,n)_{m+1} \), and similarly \( \psi_{m+1} \psi_m \psi_{m+1} \otimes (u \otimes v \otimes y) = \psi_{m+2} \psi_m \psi_{m+2} \otimes (u \otimes v \otimes y) \). Thus in all cases, this braid relation honestly holds. This then reduces us to the case \( \ell(w) = 1 \) as such relations decrease length by at most 1. For example,

\[
\psi_m \psi_{m-1} \psi_m \otimes (u \otimes v \otimes y) = \psi_{m-1} \psi_m \psi_{m-1} \otimes (u \otimes v \otimes y) = \psi_{m-1} \psi_m \otimes (u' \otimes v \otimes y). \quad (6.53)
\]

When \( \ell(w) = 1 \) either \( w = s_m \) or \( w = s_{m+1} \). For \( h = \psi_b \) the only relation that is length decreasing is \( (1.28) \) (which decreases length by at most one, when \( b = m \) or \( m + 1 \)), for which we compute

\[
\psi_m \psi_m \otimes (u \otimes v \otimes y) = (x_m^a + x_{m+1}^{-1})_1 \otimes (u \otimes v \otimes y) = 1_{i(m,n)} \otimes (x_m^a u) \otimes (x_1^{-1} v) \otimes y = 0 \in K \quad (6.54)
\]

by \( (6.48) \) since \( a \geq m \), and \(-j,i \geq 1 \). Similarly,

\[
\psi_{m+1} \psi_{m+1} \otimes (u \otimes v \otimes y) = 1_{i(m,n)} \otimes u \otimes (x_1^{-1} v) \otimes y + 1_{i(m,n)} \otimes u \otimes (x_m^a y) = 0 \in K \quad (6.55)
\]

as \( a \geq n \). In conclusion, \( K \) is indeed a submodule and in fact generated by

\[
\psi_{m+1} \otimes (u_r \otimes v \otimes y_s), \quad \text{and} \quad \psi_m \otimes (u_r \otimes v \otimes y_s). \quad (6.56)
\]

For part \( 2 \) note \( w(i(m,n)) = i(c-r, r) \) for some \( r \), but \( r \neq n \) when \( \ell(w) > 0 \) for minimal length \( w \in S_{m+1-n}/S_m \times S_1 \times S_n \). In other words, \( \psi_{\overline{z}} \otimes (u_r \otimes v \otimes y_s) \) is a weight vector and \( 1_{i(m,n)} \psi_{\overline{z}} \otimes (u_r \otimes v \otimes y_s) = 0 \) when \( \ell(w) > 0 \). That is, for all \( z \in Q = \text{Ind } L(i^m) \otimes \text{Ind } L(j) \otimes L(i^n)/K \), \( 1_{i(m,n)} z = z \), but \( 1_{i(c-r,r)} z = 0 \) when \( r \neq n \). Hence all constituents of ch(Q) have the form \( i^m j^n \).

By Frobenius reciprocity, and the irreducibility of \( L(i^m) \), we have an injection

\[
L(i^m) \otimes L(j) \otimes L(i^n) \hookrightarrow \text{Res}_{m_i,n} Q \quad (6.57)
\]

which is also a surjection by the above arguments. Hence

\[
\text{ch}(Q) = [m]^a_i [n]^b_i i^m j^n. \quad (6.58)
\]

Note that, up to grading shift, \( Q \) is none other than \( L(i^m j^n) \) and we have shown this is the unique simple quotient of \( \text{Ind } L(i^m) \otimes L(j) \otimes L(i^n) \). The uniqueness statements of Theorem 6.9 follow by Frobenius reciprocity.

Next we will give a generators and relations proof that

\[
\bar{f}_i \mathcal{L}(n) \cong \bar{f}_i \mathcal{L}(n) \cong \text{Ind } \mathcal{L}(n) \otimes L(i). \quad (6.59)
\]

Just as in the proof of Theorem 6.9,

\[
\text{ch}(\text{Ind } \mathcal{L}(n) \otimes L(i)) = [a - n]^a_i [n + 1]^b_i k^{a-n} k^{n+1} + q^{-(a_{i,j})}([a - n + 1]^a_i [n]^b_i k^{a+n+1} k^n, \quad (6.60)
\]

and since \( L(i^m) \) is irreducible with dimension \( m! \), either \( \text{ch}(\tilde{f}_i L(n)) = [a-n]_{i}^{1} [n+1]_{i}^{1} j^{a-n} j^{n+1} \) or \( \text{ch}(\tilde{f}_i L(n)) = \text{ch}(\text{Ind} L(n) \boxtimes L(i)) \).

In the latter case, \( \text{Ind} L(n) \boxtimes L(i) \) is isomorphic to \( \tilde{f}_i L(n) \), so by the Jump Lemma it is irreducible and isomorphic to \( \tilde{f}_i L(n) \). In the former case, we clearly have

\[
0 \rightarrow K \rightarrow \text{Ind} L(i^{a-n}) \boxtimes L(j) \boxtimes L(i^{n+1}) \rightarrow \tilde{f}_i L(n) \tag{6.61}
\]

by Frobenius reciprocity.

The \( R((a+1)i+j) \)-module \( \text{Ind} L(i^{a-n}) \boxtimes L(j) \boxtimes L(i^{n+1}) \) has a weight basis given by

\[
\{ \psi_{v_i} \otimes (u_r \otimes v \otimes y_s) \mid w \in S_{a+2}/S_{a-n} \times S_1 \times S_{n+1}, 1 \leq r \leq (a-n)! , 1 \leq s \leq (n+1)! \}. \tag{6.62}
\]

Let \( i = i(a-n,n+1) \). Note, for all minimal left coset representatives \( w \in S_{a+2}/S_{a-n} \times S_1 \times S_{n+1} \) that \( w(i) \neq i \) unless \( w = \text{id} \), i.e. unless \( \ell(w) = 0 \). (In fact \( w(i) = i(a-r+1,r) \) for some \( r \).) Since \( 1_{i(a-r+1,r)} \tilde{f}_i L(n) = 0 \) if \( r \neq n+1 \) by assumption, we must have

\[
K = \text{span} \{ \psi_{v_i} \otimes (u_r \otimes v \otimes y_s) \mid \ell(w) > 0 \}. \tag{6.63}
\]

We will show that \( K \) is not a proper submodule.

Pick \( u \in L(i^{a-n}) \), \( y \in L(i^{n+1}) \) so that \( x_{a-n}^{a-n-1} u = u' \neq 0 \), \( x_1^{n} y = y' \neq 0 \) so that

\[
x_{a-n}^{a-n-1} \cdot x_{a-n}^{n} (1_i \otimes (u \otimes v \otimes y)) = 1_i \otimes (u' \otimes v \otimes y') \neq 0, \tag{6.64}
\]

but

\[
x_{a-n}^{a-1-k} u = 0 \quad \text{if} \ k < n \tag{6.65}
\]

and

\[
x_{a-n}^{k} y = 0 \quad \text{if} \ k > n. \tag{6.66}
\]

Also recall \( u' \) generates \( L(i^{a-n}) \) and \( y' \) generates \( L(i^{n+1}) \) so \( 1_i \otimes (u' \otimes v \otimes y') \) generates the module \( \text{Ind} L(i^{a-n}) \boxtimes L(j) \boxtimes L(i^{n+1}) \). By assumption, \( K \ni \psi_{a-n+1} \otimes (u \otimes v \otimes y) \) and \( K \ni \psi_{a-n} \otimes (u \otimes v \otimes y) \).

If \( K \) is a \( R((a+1)i+j) \)-submodule, \( K \) also contains

\[
(\psi_{a-n+1} \psi_{a-n} \psi_{a-n+1} - \psi_{a-n} \psi_{a-n+1} \psi_{a-n}) \otimes (u \otimes v \otimes y) \]

\[
\overset{(6.39)}{=} \left( \sum_{k=0}^{a-1} x_{a-n}^{a-1-k} x_{a-n}^{-k} \right) \otimes (u \otimes v \otimes y) \overset{(6.39)}{=} 0 + 1_i \otimes (u' \otimes v \otimes y') \neq 0.
\]

Therefore \( K \ni 1_i \otimes (u' \otimes v \otimes y') \), hence \( K \) contains all of \( \text{Ind} L(i^{a-n}) \boxtimes L(j) \boxtimes L(i^{n+1}) \) contradicting that \( K \) is a proper submodule. We must have \( \tilde{f}_i L(n) \cong \text{Ind} L(n) \boxtimes L(i) \). Now \( (6.39) \) in Theorem \( 6.10 \) follows for general \( m \) from the \( m = 1 \) case as before.

Note that the Structure Theorems do not depend on the characteristic of \( \mathbb{k} \). Just as the dimensions of simple \( R(m\iota) \)-modules are independent of char \( \mathbb{k} \), so are the dimensions of simple \( R(c\iota+j) \)-modules. In fact, Kleshchev and Ram have conjectured [KR09] that the dimensions of all simple \( R(\nu) \)-modules are independent of char \( \mathbb{k} \) for finite Cartan datum.
6.4 Understanding $\varphi^A_i$

The following theorems measure how the crystal data differs for $M$ and $\tilde{f}_j M$.

**Theorem 6.12.** Let $M$ be an irreducible $R(\nu)$-module $\Lambda \in P^+$ such that $\text{pr}_\Lambda M \neq 0$ and $\text{pr}_\Lambda \tilde{f}_j M \neq 0$. Let $m = \varepsilon_i(M)$, $k = \varphi^A_i(M)$. Then there exists an $n$ with $0 \leq n \leq a$ such that $\varepsilon_i(\tilde{f}_j M) = m - (a - n)$ and $\varphi^A_i(\tilde{f}_j M) = k + n$.

**Proof.** This follows from Theorem 6.19 which proves the theorem in the case $\nu = ci + dj$ and from Proposition 6.20 which reduces it to this case. \[\square\]

One important rephrasing of the Theorem is

$$\varphi^A_i(\tilde{f}_j M) - \varepsilon_i(\tilde{f}_j M) = a + (\varphi^A_i(M) - \varepsilon(M)) = -\langle h_i, \alpha_j \rangle + (\varphi^A_i(M) - \varepsilon(M)). \quad (6.67)$$

First we introduce several lemmas that will be needed.

**Lemma 6.13.** Suppose $c + d \leq a$.

i) $\text{Ind} \mathcal{L}(i^c j^d) \boxtimes L(i^m)$ has irreducible cosocle equal to

$$\tilde{f}^m_i \mathcal{L}(i^c j^d) = \tilde{f}^{m+d}_i \mathcal{L}(i^c j) = \left\{ \begin{array}{ll} \text{Ind} \mathcal{L}(a - c) \boxtimes L(i^{m-a+c+d}) & \text{if } m \geq a - (c + d) \\ \mathcal{L}(i^c j^{d+m}) & \text{if } m < a - (c + d). \end{array} \right. \quad (6.68)$$

ii) Suppose there is a nonzero map

$$\text{Ind} \mathcal{L}(c_1) \boxtimes \mathcal{L}(c_2) \boxtimes \cdots \boxtimes \mathcal{L}(c_r) \boxtimes L(i^m) \rightarrow Q \quad (6.69)$$

where $Q$ is irreducible. Then $\varepsilon_i(Q) = m + \sum_{t=1}^r c_t$ and $\varepsilon'_i(Q) = m + \sum_{t=1}^r (a - c_t)$.

iii) Let $B$ and $Q$ be irreducible and suppose there is a nonzero map $\text{Ind} B \boxtimes \mathcal{L}(c) \rightarrow Q$. Then $\varepsilon_i(Q) = \varepsilon_i(B) + c$.

**Proof.** Part [i] follows from the Structure Theorems 6.9, 6.10 for irreducible $R((c + d + m)i + j)$-modules. For part [ii] recall $\text{Ind} \mathcal{L}(c) \boxtimes L(i^m)$ is irreducible and is isomorphic to $\text{Ind} L(i^m) \boxtimes \mathcal{L}(c)$ by Part [i] of Theorem 6.10. Consider the chain of homogeneous surjections

$$\text{Ind} \mathcal{L}(i^{a-c_1} j) \boxtimes \mathcal{L}(c_2) \boxtimes \cdots \boxtimes \mathcal{L}(c_r) \boxtimes L(i^{c_1+m})$$

$$\text{Ind} \mathcal{L}(i^{a-c_1} j) \boxtimes L(i^{c_1}) \boxtimes \mathcal{L}(c_2) \boxtimes \cdots \boxtimes \mathcal{L}(c_r) \boxtimes L(i^m)$$

$$\text{Ind} \mathcal{L}(c_1) \boxtimes \mathcal{L}(c_2) \boxtimes \cdots \boxtimes \mathcal{L}(c_r) \boxtimes L(i^m)$$

$$\rightarrow Q$$

Iterating this process we get a surjection

$$\text{Ind} \mathcal{L}(i^{a-c_1} j) \boxtimes \mathcal{L}(i^{a-c_2} j) \boxtimes \cdots \boxtimes \mathcal{L}(i^{a-c_r} j) \boxtimes L(i^h) \rightarrow Q \quad (6.71)$$
where \( h = m + \sum_{t=1}^{r} c_t \). This shows that \( \varepsilon_i(Q) = m + \sum_{t=1}^{r} c_t \). The computation of \( \varepsilon_i^\vee(Q) \) is similar.

For part (iii) let \( b = \varepsilon_i(B) \). By the Shuffle Lemma \( \varepsilon_i(Q) \leq b + c \). Further there exists an irreducible module \( C \) such that \( \varepsilon_i(C) = 0 \) and \( \text{Ind } C \boxtimes L(i^b) \rightarrow B \). By the exactness of induction, we have a surjection

\[
\text{Ind } C \boxtimes L(c) \boxtimes L(i^b) \cong \text{Ind } C \boxtimes L(i^b) \boxtimes L(c) \twoheadrightarrow Q \tag{6.72}
\]

and so by Frobenius reciprocity \( \varepsilon_i(Q) \geq \varepsilon_i(L(c)) + \varepsilon_i(L(i^b)) = c + b \).

**Lemma 6.14.** Let \( N \) be an irreducible \( R(ci + dj) \)-module with \( \varepsilon_i(N) = 0 \). Suppose \( c + d > 0 \).

i) There exists irreducible \( \bar{N} \) with \( \varepsilon_i(\bar{N}) = 0 \) and a surjection

\[
\text{Ind } \bar{N} \boxtimes L(i^b j) \twoheadrightarrow N \tag{6.73}
\]

with \( b \leq a \).

ii) There exists an \( r \in \mathbb{N} \) and \( b_t \leq a \) for \( 1 \leq t \leq r \) such that

\[
\text{Ind } L(i^{b_1} j) \boxtimes L(i^{b_2} j) \boxtimes \cdots \boxtimes L(i^{b_r} j) \twoheadrightarrow N. \tag{6.74}
\]

**Proof.** First, we may assume \( \bar{e}_j N \neq 0 \) or else \( N \) would be the trivial module \( 1 \), i.e. \( c = d = 0 \).

Let \( b = \varepsilon_i(\bar{e}_j N) \) and let \( \bar{N} = \bar{e}_i \bar{e}_j N \) so that \( \varepsilon_i(\bar{N}) = 0 \). There exists a surjection

\[
\text{Ind } \bar{N} \boxtimes L(i^b) \boxtimes L(j) \twoheadrightarrow N. \tag{6.75}
\]

Recall \( \varepsilon_i(N) = 0 \) and by the Structure Theorems, \( \text{Ind } L(i^b) \boxtimes L(j) \) has at most one composition factor with \( \varepsilon_i = 0 \), namely \( L(i^b j) \) in the case \( b \leq a \). In the case \( b > a \) it has no such composition factors, contradicting \( \varepsilon_i(N) = 0 \). Hence \( b \leq a \) and the above map must factor through

\[
\text{Ind } \bar{N} \boxtimes L(i^{b_r} j) \twoheadrightarrow N. \tag{6.76}
\]

For part (iii) we merely repeat the argument from part (i) using the exactness of induction.

**Lemma 6.15.** Suppose \( Q \) is irreducible and we have a surjection

\[
\text{Ind } L(i^{b_1} j) \boxtimes L(i^{b_2} j) \boxtimes \cdots \boxtimes L(i^{b_r} j) \boxtimes L(i^g) \twoheadrightarrow Q. \tag{6.77}
\]

i) Then for \( h \gg 0 \) we have a surjection

\[
\text{Ind } L(a - b_1) \boxtimes L(a - b_2) \boxtimes \cdots \boxtimes L(a - b_r) \boxtimes L(i^g) \twoheadrightarrow Q \tag{6.78}
\]

where \( g = h - \sum_{t=1}^{r} (a - b_t) \).

ii) In the case \( h < ar - \sum_{t=1}^{r} b_t \), we have

\[
\text{Ind } L(i^{b_1} j) \boxtimes \cdots \boxtimes L(i^{b_r-1} j) \boxtimes L(i^{b_r-1} j i^g) \boxtimes L(a - b_{r+1}) \boxtimes \cdots \boxtimes L(a - b_r) \twoheadrightarrow Q \tag{6.79}
\]
where \( g' = h - \sum_{t=s+1}^{r} (a - b_t) \) and \( s \) is such that
\[
\sum_{t=s+1}^{r} (a - b_t) \leq h < \sum_{t=s}^{r} (a - b_t).
\] (6.80)

**Proof.** Observe that \( \varepsilon_i(Q) = h \). Similar to Lemma 6.13 when \( d = 0 \), \( \text{Ind} \mathcal{L}(i^{b_r}) \boxtimes L(i^h) \) has a unique composition factor with \( \varepsilon_i = h \), namely \( \text{Ind} L(i^{h-(a-b_r)}) \boxtimes L(a-b_r) \) in the case \( h \geq a-b_r \) and \( \mathcal{L}(i^{b_r} j^h) \) otherwise. In the latter case, we are done, and note we fall into case \( \text{II} \) with \( s = r \). In the former case, we get a surjection
\[
\text{Ind} \mathcal{L}(i^{b_1} j) \otimes \cdots \otimes \mathcal{L}(i^{b_{r-1}} j) \boxtimes L(i^{h-(a-b_r)}) \boxtimes L(a-b_r) \to Q.
\] (6.81)

We apply the same reasoning to \( \text{Ind} \mathcal{L}(i^{b_{r-1}} j) \boxtimes L(i^{h-(a-b_r)}) \) noting that by Lemma 6.13 (iii), since \( \varepsilon_i(L(a-b_r)) = a-b_r = \varepsilon_i(Q) - (h-(a-b_r)) \) we want to pick out the unique composition factor with \( \varepsilon_i = h - (a-b_r) \). As above, this is \( \text{Ind} L(i^{h-(\sum_{t=r-1}^{r} b_t)}) \boxtimes L(a-b_{r-1}) \) for \( h \) large enough and \( \mathcal{L}(i^{b_{r-1}} j^{h-(a-b_r)}) \) otherwise. Continuing in this vein the lemma follows. \( \square \)

**Lemma 6.16.** Let \( M \) be an irreducible \( R(\nu) \)-module and suppose we have a nonzero map
\[
\text{Ind} A \otimes B \otimes L(i^h) \xrightarrow{f} M
\] (6.82) where \( \varepsilon_i(A) = 0 \) and \( B \) is irreducible. Then there exists a surjective map
\[
\text{Ind} A \otimes \tilde{f}_i^h B \twoheadrightarrow M
\] (6.83)

**Proof.** First note \( \varepsilon_i(M) = \varepsilon_i(B) + h \) since by Frobenius reciprocity \( \varepsilon_i(M) \geq \varepsilon_i(B) + h \), but by the Shuffle Lemma \( \varepsilon_i(M) \leq \varepsilon_i(B) + h \) since \( \varepsilon_i(A) = 0 \). Consider \( \text{Ind} B \otimes L(i^h) \). This has unique irreducible quotient \( \tilde{f}_i^h B \) with \( \varepsilon_i(\tilde{f}_i^h B) = \varepsilon_i(B) + h \) and has all other composition factors \( U \) with \( \varepsilon_i(U) < \varepsilon_i(B) + h = \varepsilon_i(M) \), by Section 2.5.1. Hence, for any such \( U \) there does not exist a nonzero map \( \text{Ind} A \otimes U \to M \). In particular, letting \( K \) be the maximal submodule such that
\[
0 \longrightarrow K \longrightarrow \text{Ind} B \otimes L(i^h) \longrightarrow \tilde{f}_i^h B \longrightarrow 0
\] (6.84) is exact, the above map \( f \) must restrict to zero on the submodule \( \text{Ind} A \otimes K \) and hence \( f \) factors through \( \text{Ind} A \otimes \tilde{f}_i^h B \to M \), which is nonzero and thus surjective. \( \square \)

**Lemma 6.17.** Let \( A \) be an irreducible \( R(\nu) \)-module with \( \text{pr}_A A \neq 0 \) and \( k = \varphi_A^\Lambda(A) \).

\[ \text{i) } \text{Let } U \text{ be an irreducible } R(\mu) \text{-module and let } t \geq 1. \text{ Then } \text{pr}_A \text{Ind} A \otimes L(i^{k+t}) \otimes U = 0. \]
\[ \text{ii) } \text{Let } B \text{ be irreducible with } \varepsilon_i^U(B) > k. \text{ Then } \text{pr}_A \text{Ind} A \otimes B = 0. \text{ In particular, if } Q \text{ is any irreducible quotient of } \text{Ind} A \otimes B, \text{ then } \text{pr}_A Q = 0. \]

**Proof.** Recall for a module \( B \), \( \text{pr}_A B = B/\mathcal{J}^A B \) and so \( \text{pr}_A B = 0 \) if and only if \( B = \mathcal{J}^A B \). Since \( A \), \( L(i^{k+t}) \), and \( U \) are all irreducible, each is cyclically generated by any nonzero element. Let us pick nonzero \( w \in A, v \in L(i^{k+t}), u \in U \). Further \( \text{Ind} A \otimes L(i^{k+t}) \) is cyclically generated as an \( R(\nu + (k+t)i) \)-module by \( 1_{\nu + (k+t)i} \otimes w \otimes v \) and likewise \( \text{Ind} A \otimes L(i^{k+t}) \otimes U \) is cyclically generated as an \( R(\nu + (k+t)i + \mu) \)-module by \( 1_{\nu + (k+t)i + \mu} \otimes w \otimes v \otimes u \).
Recall that Ind $A \boxtimes L(i^{k+t})$ has a unique simple quotient $\tilde{j}_i^{k+t} A$ and that pr$_A \tilde{j}_i^{k+t} A = 0$ because $\varphi_i^A(A) = k$. Since pr$_A$ is right exact, pr$_A$ Ind $A \boxtimes L(i^{k+t}) = 0$. Consequently $\mathcal{J}^A_{\nu + (k+t)i} Ind A \boxtimes L(i^{k+t}) = Ind A \boxtimes L(i^{k+t})$. In particular, there exists an $\eta \in \mathcal{J}^A_{\nu + (k+t)i}$ such that

$$\eta 1_{\nu + (k+t)i} \otimes w \otimes v = 1_{\nu + (k+t)i} \otimes w \otimes v. \quad (6.85)$$

But then

$$\eta 1_{\nu + (k+t)i+\mu} \otimes w \otimes v \otimes u = 1_{\nu + (k+t)i+\mu} \otimes w \otimes v \otimes u. \quad (6.86)$$

Note we can consider $\eta$ as an element of $\mathcal{J}^A_{\nu + (k+t)i+\mu}$ as well via the canonical inclusion $R(\nu + (k+t)i) \hookrightarrow R(\nu + (k+t)i+\mu)$. Hence

$$\mathcal{J}^A_{\nu + (k+t)i+\mu} Ind A \boxtimes L(i^{k+t}) \boxtimes U = Ind A \boxtimes L(i^{k+t}) \boxtimes U \quad (6.87)$$

and so pr$_A$ Ind $A \boxtimes L(i^{k+t}) \boxtimes U = 0$.

For part (ii), let $b = \varepsilon_i^\vee(B)$ and $C = (\varepsilon_i^\vee)^b B$ so we have Ind $L(i^b) \boxtimes C \twoheadrightarrow B$. Thus by the exactness of induction we also have a surjection Ind $A \boxtimes L(i^b) \boxtimes C \twoheadrightarrow Ind A \boxtimes B$. By part (i) and the right exactness of pr$_A$, pr$_A$ Ind $A \boxtimes B = 0$. Likewise pr$_A$ $Q = 0$ for any quotient of Ind $A \boxtimes B$.

**Lemma 6.18.** Let $A$ be an irreducible $R(\nu)$-module with pr$_A A \neq 0$ and $k = \varphi_i^A(A)$. Further suppose $\varepsilon_i(A) = \varepsilon_j(A) = 0$ and that $B$ is an irreducible $R(ci + dj)$-module with $\varepsilon_i^\vee(B) \leq k$. Let $Q$ be irreducible such that Ind $A \boxtimes B \twoheadrightarrow Q$ is nonzero. Then $\varepsilon_i^\vee(Q) \leq \lambda_i$. Further, if $\varepsilon_j^\vee(B) \leq \varphi_i^A(A)$ (or if $\lambda_j \gg 0$) then pr$_A Q \neq 0$.

**Proof.** Let $b = \varepsilon_i^\vee(B)$ and $C = (\varepsilon_i^\vee)^b B$ so that $\varepsilon_i^\vee(C) = 0$. We thus have surjections

$$\text{Ind } A \boxtimes L(i^b) \boxtimes C \twoheadrightarrow \text{Ind } A \boxtimes B \twoheadrightarrow Q. \quad (6.88)$$

Observe by Frobenius reciprocity

$$\left(1_{\nu} \otimes 1_{bi} \otimes 1_{(c-b)i+dj}\right)Q \neq 0. \quad (6.89)$$

Let $U$ be any composition factor of Ind $A \boxtimes L(i^b)$ other than $\tilde{j}_i^b A$, so that $\varepsilon_i(U) < b$. By the Shuffle Lemma $1_{\nu} \otimes 1_{bi} \otimes 1_{(c-b)i+dj} (\text{Ind } U \boxtimes C) = 0$, so there cannot be a nonzero homomorphism Ind $U \boxtimes C \twoheadrightarrow Q$. (More precisely, for every constituent $i = i_1 \ldots i_{|\nu|+b}$ of ch($U$) there exists a $y$, $|\nu| < y \leq |\nu| + b$ with $i_y \neq i$ and $i_y \neq j$. Hence by the Shuffle Lemma, for every constituent $i' = i'_1 \ldots i'_{|\nu|+c+d}$ of ch(Ind $U \boxtimes C$) there exists a $z$, $|\nu| < z \leq |\nu| + c + d$ with $i'_z \neq i$ and $i'_z \neq j$.)

Thus we must have a nonzero map

$$\text{Ind } \tilde{j}_i^b A \boxtimes C \twoheadrightarrow Q. \quad (6.90)$$

By the Shuffle Lemma, $\varepsilon_i^\vee(Q) \leq \varepsilon_i^\vee(\tilde{j}_i^b A) + \varepsilon_i^\vee(\tilde{j}_i^b C) \leq \lambda_i$ since $b \leq k = \varphi_i^A(A)$ and $\varepsilon_i^\vee(C) = 0$. Note $\varepsilon_i^\vee(Q) \leq \varepsilon_i^\vee(A) + \varepsilon_i^\vee(B)$, so for $\ell \neq i$, $\ell \neq j$ clearly $\varepsilon_i^\vee(Q) \leq \lambda_\ell$ and hence pr$_A Q \neq 0$ so long as $\varepsilon_j^\vee(B) \leq \varphi_i^A(A)$, which will for instance be assured if $\lambda_j \gg 0$.

In the following theorem and its proof all modules have support $\nu = ci + dj$ for some $c, d \in \mathbb{N}$.
Theorem 6.19. Let $M$ be an irreducible $R(ci + dj)$-module and let $\Lambda \in P^+$ be such that $pr_\Lambda M \neq 0$ and $pr_\Lambda f_j M \neq 0$. Let $m = \varepsilon_i(M)$, $k = \varphi^\Lambda_i(M)$. Then there exists an $n$ with $0 \leq n \leq a$ such that $\varepsilon_i(f_j M) = m - (a - n)$ and $\varphi^\Lambda_i(f_j M) = k + n$.

Proof. Let $N = \tilde{e}_i^m M$ so that $\varepsilon_i(N) = 0$ and we have a surjection

$$\text{Ind } N \boxtimes L(i^m) \twoheadrightarrow M. \quad (6.91)$$

Thus, we also have

$$\text{Ind } N \boxtimes L(i^m) \boxtimes L(j) \twoheadrightarrow \tilde{f}_j M. \quad (6.92)$$

By the Structure Theorems 6.9, 6.10 for simple $R(mi + j)$-modules, for each $m - a \leq \gamma \leq m$ there exists a composition factor $U_\gamma$ of $\text{Ind } L(i^m) \boxtimes L(j)$ with $\varepsilon_i(U_\gamma) = \gamma$. In particular, there is a unique $\gamma$ such that the above map induces

$$\text{Ind } N \boxtimes U_\gamma \twoheadrightarrow \tilde{f}_j M \quad (6.93)$$

as we must have $\varepsilon_i(U_\gamma) = \varepsilon_i(\tilde{f}_j M)$, since $\varepsilon_i(N) = 0$. Choose $n$ so that $\gamma = m - (a - n) = \varepsilon_i(\tilde{f}_j M)$. Note that by the Structure Theorems

$$U_\gamma \cong \begin{cases} \text{Ind } L(n) \boxtimes L(i^{m-a}) & m \geq a \\ L(i^{a-n}, \gamma) \boxtimes L(i^{m-a-n}) & m < a, \end{cases} \quad (6.94)$$

and furthermore

$$\tilde{f}_i^a U_\gamma \cong \text{Ind } L(n) \boxtimes L(i^m) \quad (6.95)$$

in both cases.

By Lemma 6.14 there exist $0 \leq b_t \leq a$ such that

$$\text{Ind } L(i^{b_1}) \boxtimes L(i^{b_2}) \boxtimes \cdots \boxtimes L(i^{b_r}) \twoheadrightarrow N \quad (6.96)$$

and hence we obtain the following surjections

$$\begin{align*}
\text{Ind } L(i^{b_1}) \boxtimes L(i^{b_2}) \boxtimes \cdots \boxtimes L(i^{b_r}) \boxtimes L(i^m) & \twoheadrightarrow M \\
\text{Ind } L(i^{b_1}) \boxtimes L(i^{b_2}) \boxtimes \cdots \boxtimes L(i^{b_r}) \boxtimes L(i^{m+h}) & \twoheadrightarrow \tilde{f}_i^h M \\
\text{Ind } L(i^{b_1}) \boxtimes L(i^{b_2}) \boxtimes \cdots \boxtimes L(i^{b_r}) \boxtimes U_{m-a+n} & \twoheadrightarrow \tilde{f}_j M \\
\text{Ind } L(i^{b_1}) \boxtimes L(i^{b_2}) \boxtimes \cdots \boxtimes L(i^{b_r}) \boxtimes U_{m-a+n} \boxtimes L(i^h) & \twoheadrightarrow \tilde{f}_i^h \tilde{f}_j M
\end{align*} \quad (6.97) \quad (6.98) \quad (6.99) \quad (6.100)$$

We first apply Lemma 6.14 to (6.98) to obtain, for $h \gg 0$ (in fact $h \geq \sum_{t=1}^r (a - b_t) - m$)

$$\text{Ind } L(a - b_1) \boxtimes L(a - b_2) \boxtimes \cdots \boxtimes L(a - b_r) \boxtimes L(i^h) \twoheadrightarrow \tilde{f}_i^h M \quad (6.101)$$

where $g = m + h - \sum_{t=1}^r (a - b_t)$. Hence, by Lemma 6.13 (iii)

$$\varepsilon_i^\gamma(\tilde{f}_i^h M) = g + \sum_{t=1}^r b_t = h + m - ar + 2 \sum_{t=1}^r b_t. \quad (6.102)$$

Further, it is clear that $\varepsilon_i^\gamma(\tilde{f}_i^{h+1}) = 1 + \varepsilon_i^\gamma(\tilde{f}_i^h (M))$. 

41
Applying Lemma \[6.15\] to (6.100) we obtain for \( h \gg 0 \)
\[
\text{Ind} L(a - b_1) \boxtimes \cdots \boxtimes L(a - b_r) \boxtimes L(n) \boxtimes L(i^m) \boxtimes L(i^{d'}) \rightarrow \tilde{f}_i^h \tilde{f}_j M
\] (6.103)
where \( g' = h - a - \sum_{t=1}^r (a - b_t) \). Note we have used (6.95) above, and in the case \( m < a \) we have also employed Lemma \[6.16\]. As above, by Lemma \[6.13 \text{(ii)}\]
\[
\varepsilon_i^y (\tilde{f}_i^h \tilde{f}_j M) = g' + m + a - n + \sum_{t=1}^r b_t
\] (6.104)
\[
= h + m - n - ar + 2 \sum_{t=1}^r b_t
\] (6.105)
\[
= \varepsilon_i^y (\tilde{f}_i^h M) - n.
\] (6.106)
Further, it is clear that \( \varepsilon_i^y (\tilde{f}_i^{h+1} \tilde{f}_j M) = 1 + \varepsilon_i^y (\tilde{f}_i^h \tilde{f}_j M) \).

For \( h \gg 0 \) we have shown that \( \varepsilon_i^y (\tilde{f}_i^h \tilde{f}_j M) = \varepsilon_i^y (\tilde{f}_i^h M) - n \). Now fix such an \( h \) and let \( \omega_i = h + (m - ar + 2 \sum_{t=1}^r b_t) \), which we may assume is positive. Let \( \omega_x = \lambda \ell \) for \( \ell \neq i \) and set \( \Omega = \sum_{i \notin I} \omega_i A_i \in P^+ \). Given these choices, we have shown \( \varepsilon_i^y (\tilde{f}_i^h M) = \omega_i \), but \( \varepsilon_i^y (\tilde{f}_i^{h+1} M) = \omega_i + 1 \). Hence \( \varphi_i^{\Omega} (M) = h \). Likewise \( \varepsilon_i^y (\tilde{f}_i^h \tilde{f}_j M) = \omega_i - n \), so that \( \varepsilon_i^y (\tilde{f}_i^{h+n} \tilde{f}_j M) = \omega_i \), but \( \varepsilon_i^y (\tilde{f}_i^{h+n+1} \tilde{f}_j M) = \omega_i + 1 \) yielding \( \varphi_i^{\Omega} (\tilde{f}_j M) = h + n \). Observe then that
\[
\varphi_i^{\Omega} (\tilde{f}_j M) - \varphi_i^{\Omega} (M) = n. \tag{6.107}
\]

By our hypotheses and the choice of \( \Omega \), we know \( \text{pr}_A \) and \( \text{pr}_\Omega \) are nonzero for both modules. Hence by Remark \[6.7\]
\[
\varphi_i^A (\tilde{f}_j M) - \varphi_i^A (M) = \varphi_i^{\Omega} (\tilde{f}_j M) - \varphi_i^{\Omega} (M) = n.
\]

We have just shown in Theorem \[6.19\] that Theorem \[6.12\] holds for all \( R(c_i + d_j) \)-modules. Next we show that to deduce the theorem for \( R(\nu) \)-modules for arbitrary \( \nu \) it suffices to know the result for \( \nu = ci + dj \).

**Proposition 6.20.** Let \( \Lambda \in P^+ \) and let \( M \) be an irreducible \( R(\nu) \)-module such that \( \text{pr}_A M \neq 0 \) and \( \text{pr}_A \tilde{f}_j M \neq 0 \). Suppose \( \varepsilon_i (M) = m \) and \( \varepsilon_i (\tilde{f}_j M) = m - (a - n) \) for some \( 0 \leq n \leq a \). Then there exists \( c, d \) and an irreducible \( R(ci + dj) \)-module \( B \) such that \( \varepsilon_i (B) = m \), \( \varepsilon_i (\tilde{f}_j B) = m - (a - n) \) and there exists \( \Omega \in P^+ \) with \( \text{pr}_\Omega (B) \neq 0, \text{pr}_\Omega (\tilde{f}_j B) \neq 0, \text{pr}_\Omega (M) \neq 0, \text{pr}_\Omega (\tilde{f}_j M) \neq 0 \), and furthermore
\[
\varphi_i^{\Omega} (\tilde{f}_j M) - \varphi_i^{\Omega} (M) = \varphi_i^{\Omega} (\tilde{f}_j B) - \varphi_i^{\Omega} (B). \tag{6.108}
\]

Note that by Remark \[6.7\] \( \varphi_i^A (\tilde{f}_j M) - \varphi_i^A (M) = \varphi_i^{\Omega} (\tilde{f}_j M) - \varphi_i^{\Omega} (M) \), so once we prove this proposition, it together with Theorem \[6.19\] proves Theorem \[6.12\]

**Proof.** Let \( N = c_i^m M \), so that \( \varepsilon_i (N) = 0 \). Then there exists irreducible modules \( A \) and \( \overline{B} \) with a surjection \( \text{Ind} A \boxtimes \overline{B} \rightarrow N \) such that \( \varepsilon_j (A) = \varepsilon_j (\overline{B}) = 0 \) and \( \overline{B} \) is an \( R(ci + dj) \)-module for some \( \tilde{c}, d \). (For instance, one may construct \( A \) by setting
\[
A_1 = N, \quad A_{2r} = c_j^{\varepsilon_j (A_{2r-1})} A_{2r-1}, \quad A_{2r+1} = \tilde{c}_i^{\varepsilon_i (A_{2r})} A_{2r}, \tag{6.109}
\]
which eventually stabilizes. So we may set \( A = A_r \) for \( r \gg 0 \).

Observe, as \( \varepsilon_i(A) = \varepsilon_j(A) = 0 \), we must have \( \varepsilon_i(B) = \varepsilon_i(N) = 0 \) and \( \varepsilon_j(B) = \varepsilon_j(N) \). Hence we also have a surjection

\[
\text{Ind } A \otimes B \otimes L(i^m) \twoheadrightarrow M
\]

(6.110)

which by Lemma 6.16 produces a map

\[
\text{Ind } A \otimes B \twoheadrightarrow M
\]

(6.111)

where \( B = \tilde{f}_i^m B \). Observe \( \varepsilon_i(B) = \varepsilon_i(M) = m \). We have a surjection

\[
\text{Ind } A \otimes B \otimes L(j) \twoheadrightarrow \tilde{f}_j M
\]

(6.112)

and since \( \varepsilon_j(B) = \varepsilon_j(M) \), Lemma 6.16 again produces a map

\[
\text{Ind } A \otimes \tilde{f}_j B \twoheadrightarrow \tilde{f}_j M.
\]

(6.113)

Again observe \( \varepsilon_i(\tilde{f}_j B) = \varepsilon_i(\tilde{f}_j M) = m - (a - n) \). From (6.111) and (6.113) we also have nonzero maps

\[
\text{Ind } A \otimes B \otimes L(i^h) \twoheadrightarrow \tilde{f}_i^h M, \quad \text{Ind } A \otimes \tilde{f}_j B \otimes L(i^{h'}) \twoheadrightarrow \tilde{f}_i^{h'} \tilde{f}_j M
\]

(6.114)

so applying Lemma 6.16 there exist surjections

\[
\text{Ind } A \otimes \tilde{f}_i^h B \twoheadrightarrow \tilde{f}_i^h M, \quad \text{Ind } A \otimes \tilde{f}_i^{h'} \tilde{f}_j B \twoheadrightarrow \tilde{f}_i^{h'} \tilde{f}_j M.
\]

(6.115)

Let \( \Omega = \sum_{i \in I} \omega_i \Lambda_i \in \mathbb{P}^+ \) be such that \( \omega_\ell = \max\{\lambda_\ell, \varepsilon_\ell B\} \) for all \( \ell \in I \). Recall \( B \) is an \( R(ci + dj) \)-module, where \( c = \tilde{c} + m \), so for \( \ell \neq i, j \), \( \varepsilon_\ell B = 0 \). Take \( h = \varphi_i^\Omega(M) \) and \( h' = \varphi_i^\Omega(\tilde{f}_j M) \) so that \( \text{pr}_\Omega(\tilde{f}_i^h M) \neq 0 \), \( \text{pr}_\Omega(\tilde{f}_i^{h'} \tilde{f}_j M) \neq 0 \), but \( \text{pr}_\Omega(\tilde{f}_i^{h + 1} M) = \text{pr}_\Omega(\tilde{f}_i^{h + 1} \tilde{f}_j M) = 0 \).

From the contrapositive to Lemma 6.17 (ii) applied to (6.115) we deduce

\[
\varepsilon_i^\vee(\tilde{f}_i^h B) \leq \varphi_i^\Omega(A), \quad \varepsilon_i^\vee(\tilde{f}_i^{h'} \tilde{f}_j B) \leq \varphi_i^\Omega(A).
\]

(6.116)

However, applying the contrapositive of Lemma 6.18

\[
\varepsilon_i^\vee(\tilde{f}_i^{h + 1} B) > \varphi_i^\Omega(A), \quad \varepsilon_i^\vee(\tilde{f}_i^{h'} \tilde{f}_j B) > \varphi_i^\Omega(A).
\]

(6.117)

We thus conclude

\[
\varepsilon_i^\vee(\tilde{f}_i^h B) = \varphi_i^\Omega(A) = \varepsilon_i^\vee(\tilde{f}_i^{h'} \tilde{f}_j B)
\]

(6.118)

and furthermore \( \text{jump}_i(\tilde{f}_i^{h} B) = \text{jump}_i(\tilde{f}_i^{h'} \tilde{f}_j B) = 0 \).

Recall that \( \varphi_i^\Omega(C) = 1 + \varphi_i^\Omega(\tilde{f}_i C) \) for any irreducible module \( C \). Hence, we compute

\[
\varphi_i^\Omega(\tilde{f}_j B) - \varphi_i^\Omega(B) = (h' + \varphi_i^\Omega(\tilde{f}_i^{h'} \tilde{f}_j B)) - (h + \varphi_i^\Omega(\tilde{f}_i^h B))
\]

\[
= (h' - h) + \varphi_i^\Omega(\tilde{f}_i^{h'} \tilde{f}_j B) - \varphi_i^\Omega(\tilde{f}_i^h B)
\]

(Prop 6.6 \( \downarrow \))

\[
= (h' - h) + (\text{jump}_i(\tilde{f}_i^{h'} \tilde{f}_j B) - \varepsilon_i^\vee(\tilde{f}_i^{h'} \tilde{f}_j B) + \omega_i)
\]

\[
- (\text{jump}_i(\tilde{f}_i^h B) - \varepsilon_i^\vee(\tilde{f}_i^h B) + \omega_i)
\]

\[
= (h' - h) + (0 - \varphi_i^\Omega(A) + \omega_i) - (0 - \varphi_i^\Omega(A) + \omega_i)
\]

\[
= h' - h
\]

\[
= \varphi_i^\Omega(\tilde{f}_j M) - \varphi_i^\Omega(M).
\]
**Corollary 6.21** (Corollary of Theorem [6.12]). Let \( \Lambda = \sum_{i \in I} \lambda_i \Lambda_i \in P^+ \) and let \( M \) an irreducible \( R(\nu) \)-module such that \( \text{pr}_\Lambda M \neq 0 \). Then
\[
\varphi_i^\Lambda(M) = \lambda_i + \varepsilon_i(M) + \text{wt}_i(M).
\]

*Proof.* The proof is by induction on the length \( |\nu| \). For \( |\nu| = 0 \) we have \( M = 1 \) and \( \text{wt}(M) = 0 \). For all \( i \in I \) observe that \( \varphi_i^\Lambda(1) = \lambda_i, \varepsilon_i(1) = 0, \) and \( \text{wt}_i(M) = 0 \), so that the claim clearly holds for \( M = 1 \). Fix \( \nu \) with \( |\nu| > 0 \) and an irreducible \( R(\nu) \)-module \( M \). Let \( j \in I \) be such that \( \varepsilon_j(M) \neq 0 \), noting such \( j \) exists since \( |\nu| > 0 \).

Consider \( N = \tilde{e}_j M \). By induction we may assume the claim holds for \( N \). Note \( M = \tilde{f}_j N \). By Theorem [6.12] and its rephrasing (6.67), for any \( i \in I \)
\[
\varphi_i^\Lambda(M) = \varphi_i^\Lambda(\tilde{f}_j N) = \varphi_i^\Lambda(N) + \varepsilon_i(\tilde{f}_j N) - \varepsilon_i(N) + a_{ij}
= (\lambda_i + \varepsilon_i(N) + \text{wt}_i(N)) + \varepsilon_i(\tilde{f}_j N) - \varepsilon_i(N) + a_{ij}
= \lambda_i + \varepsilon_i(\tilde{f}_j N) + \text{wt}_i(N) - \langle h_i, \alpha_j \rangle
= \lambda_i + \varepsilon_i(M) + \text{wt}_i(M).
\]

\[\square\]

Note that we have finally proved Proposition [6.6][\text{v}]. By Remark [2.3] given an irreducible module \( M \) we can always take \( \Lambda \) large enough so that \( \text{pr}_\Lambda M \neq 0 \), and then Proposition [6.6][\text{v}]
combined with the above corollary gives
\[
\text{jump}_i(M) = \varphi_i^\Lambda(M) + \varepsilon_i^\Lambda(M) + \lambda_i
= (\lambda_i + \varepsilon_i(M) + \text{wt}_i(M)) + \varepsilon_i^\Lambda(M) - \lambda_i
= \varepsilon_i(M) + \varepsilon_i^\Lambda(M) + \text{wt}_i(M).
\]

As mentioned in the partial proof of Proposition [6.6] above, the \( \sigma \)-symmetry of this characterization of \( \text{jump}_i(M) \) now implies the remaining parts [\text{i}, \text{ii}] of that proposition. In the next section, we will use all characterizations of \( \text{jump}_i(M) \) from Proposition [6.6]

### 7 Identification of crystals – “Reaping the Harvest”

Now that we have built up the machinery of Section [6] we can prove the module theoretic crystal \( \mathcal{B} \) is isomorphic to \( B(\infty) \). Once we have completed this step, it is not much harder to show \( \mathcal{B}^\Lambda \cong B(\Lambda) \).

#### 7.1 Constructing the strict embedding \( \Psi \)

Recall Proposition [6.2] that said \( \varepsilon_i^\Lambda(\tilde{f}_j M) = \varepsilon_i^\Lambda(M) \) when \( i \neq j \) but when \( i = j \) either \( \varepsilon_i^\Lambda(\tilde{f}_i M) = \varepsilon_i^\Lambda(M) \) or \( \varepsilon_i^\Lambda(M) + 1 \).

**Proposition 7.1.** Let \( M \) be a simple \( R(\nu) \)-module, and write \( c = \varepsilon_i^\Lambda(M) \).

i) Suppose \( \varepsilon_i^\Lambda(\tilde{f}_i M) = \varepsilon_i^\Lambda(M) + 1 \). Then
\[
\varepsilon_i^\Lambda \tilde{f}_i M \cong M
\]
up to grading shift.
ii) Suppose $\varepsilon_i^\vee(\tilde{f}_j M) = \varepsilon_j^\vee(M)$ where $i$ and $j$ are not necessarily distinct. Then

$$\langle \varepsilon_i^\vee \rangle^c(\tilde{f}_j M) \cong \tilde{f}_j(\varepsilon_i^\vee c M)$$

(7.2)

up to grading shift.

**Proof.** For part (i), the Jump Lemma 6.5 gives us $\tilde{f}_i M \cong \tilde{f}_i^\vee M$. Therefore, $\bar{\varepsilon}_i^\vee \tilde{f}_i M \cong \varepsilon_i^\vee \tilde{f}_i^\vee M$.

For part (ii) let $\tilde{M} = (\varepsilon_i^\vee c M)$ so that $\varepsilon_i^\vee(\tilde{M}) = 0$ and we have a surjection $\text{Ind } L(i^c) \boxtimes \tilde{M} \twoheadrightarrow M$ as well as

$$\text{Ind } L(i^c) \boxtimes \tilde{M} \boxtimes L(j) \twoheadrightarrow \tilde{f}_j M.$$  

(7.3)

Note that as $c = \varepsilon_i^\vee(\tilde{f}_j M)$, all composition factors of $(\varepsilon_j^\vee c f_j M)$ are, up to grading shift, isomorphic to $(\bar{\varepsilon}_j^\vee c f_j M)$, so there exists a surjection $(\varepsilon_j^\vee c f_j M) \twoheadrightarrow (\varepsilon_j^\vee c f_j M)$. As $(\varepsilon_i^\vee) c$ is exact, we may apply it to (7.3) and compose with the map above yielding

$$(\varepsilon_i^\vee c)(\text{Ind } L(i^c) \boxtimes \tilde{M} \boxtimes L(j)) \twoheadrightarrow (\bar{\varepsilon}_i^\vee c \tilde{f}_j M).$$

(7.4)

In the case $j \neq i$, by the Mackey Theorem [KL09] Proposition 2.8 $(\varepsilon_j^\vee c)(\text{Ind } L(i^c) \boxtimes \tilde{M} \boxtimes L(j))$ has a filtration whose subquotients are isomorphic (up to grading shift) to $\text{Ind } \tilde{M} \boxtimes L(j)$. So (7.4) yields a map

$$\text{Ind } \tilde{M} \boxtimes L(j) \twoheadrightarrow (\varepsilon_i^\vee c \tilde{f}_j M),$$

(7.5)

which implies

$$\langle \bar{\varepsilon}_i^\vee c \rangle \tilde{f}_j M \cong \tilde{f}_j \tilde{M} \cong \tilde{f}_j (\varepsilon_i^\vee c M).$$

(7.6)

In the case $j = i$, the subquotients are isomorphic to $\text{Ind } \tilde{M} \boxtimes L(i)$ or $\text{Ind } L(i) \boxtimes \tilde{M}$. But, by assumption $\varepsilon_i^\vee((\varepsilon_i^\vee c f_i) M) = 0$, so by Frobenius reciprocity we cannot have a nonzero map from $\text{Ind } L(i) \boxtimes \tilde{M}$ to $(\varepsilon_i^\vee c f_i) M$. As before, we must have

$$\text{Ind } \tilde{M} \boxtimes L(i) \twoheadrightarrow (\varepsilon_i^\vee c \tilde{f}_i M)$$

(7.7)

and so $(\varepsilon_i^\vee c \tilde{f}_i M) = (\varepsilon_i^\vee c \tilde{f}_i M) \cong \tilde{f}_i \tilde{M} = \tilde{f}_i (\varepsilon_i^\vee c M) = \tilde{f}_i (\varepsilon_i^\vee c M).$

\[ \blacksquare \]

**Proposition 7.2.** Let $M$ be an irreducible $R(\nu)$-module, and write $c = \varepsilon_i^\vee(M)$, $\tilde{M} = (\varepsilon_i^\vee) c(M)$.

i) $\varepsilon_i(M) = \max \{ \varepsilon_i(\tilde{M}), c - \text{wt}_i(M) \}$.

ii) Suppose $\varepsilon_i(M) > 0$. Then

$$\varepsilon_i^\vee(\varepsilon_i c M) = \begin{cases} c & \text{if } \varepsilon_i(\tilde{M}) \geq c - \text{wt}_i(\tilde{M}), \\ c - 1 & \text{if } \varepsilon_i(\tilde{M}) < c - \text{wt}_i(\tilde{M}). \end{cases}$$

(7.8)

iii) Suppose $\varepsilon_i(M) > 0$. Then

$$\langle \varepsilon_i^\vee \rangle^c(\varepsilon_i c M) = \begin{cases} \frac{\varepsilon_i(\tilde{M})}{M} & \text{if } \varepsilon_i(\tilde{M}) \geq c - \text{wt}_i(\tilde{M}), \\ \frac{\varepsilon_i(\til{M})}{\tilde{M}} & \text{if } \varepsilon_i(\til{M}) < c - \text{wt}_i(\til{M}). \end{cases}$$

(7.9)
Proof. Suppose $\varepsilon_i(M) > \varepsilon_i(\overline{M})$. Then $\text{jump}_i(M) = 0$ and by Proposition 6.6 (V)
\begin{equation}
0 = \text{jump}_i(M) = \varepsilon_i(M) + \varepsilon_i^{\vee}(M) + \text{wt}_i(M) = \varepsilon_i(M) + c + \text{wt}_i(\overline{M}) - 2c
\end{equation}
so that $\varepsilon_i(M) = c - \text{wt}_i(\overline{M})$, and clearly $\varepsilon_i(M) = \max \{ \varepsilon_i(\overline{M}), c - \text{wt}_i(\overline{M}) \}$. It is always the case that $\text{jump}_i(M) \geq 0$. If $\varepsilon_i(M) = \varepsilon_i(\overline{M})$, then as above $\varepsilon_i(M) = (c - \text{wt}_i(\overline{M})) + \text{jump}_i(M) \geq c - \text{wt}_i(\overline{M})$. So again $\varepsilon_i(M) = \max \{ \varepsilon_i(\overline{M}), c - \text{wt}_i(\overline{M}) \}$.

For part (iii) consider two cases.

Case 1 ($\varepsilon_i(\overline{M}) < c - \text{wt}_i(\overline{M})$): Recall by Proposition 6.6 (V), $\text{jump}_i(\overline{M}) = \varepsilon_i^{\vee}(\overline{M}) + \varepsilon_i(M) + \text{wt}_i(\overline{M}) = 0 + \varepsilon_i(\overline{M}) + \text{wt}_i(\overline{M})$ so $\text{jump}_i(\overline{M}) < c$ if and only if $\varepsilon_i(\overline{M}) < c - \text{wt}_i(\overline{M})$. Since $\text{jump}_i(\overline{M}) < c$ then $0 = \text{jump}_i((\tilde{f}_i)^c) = \text{jump}_i(\tilde{e}_i^{\vee}M)$ by (6.11). By the Jump Lemma 6.5, $\tilde{f}_i(\tilde{e}_i^{\vee}M) \cong \tilde{f}_i(\tilde{e}_i^{\vee}M) \cong M$. Hence $\tilde{e}_i^{\vee}M = \tilde{e}_iM$ and so $\varepsilon_i^{\vee}(\tilde{e}_iM) = \varepsilon_i^{\vee}(\tilde{e}_i^{\vee}M) = c - 1$.

Case 2 ($\varepsilon_i(\overline{M}) \geq c - \text{wt}_i(\overline{M})$): As above this case is equivalent to $\text{jump}_i(\overline{M}) \geq c$. Note if $c = 0$ then (iii) obviously holds by Proposition 6.2. If $c > 0$ by (6.11), we must have $0 < \text{jump}_i((\tilde{f}_i)^c) = \text{jump}_i(\tilde{e}_i^{\vee}M)$. Suppose that $\text{jump}_i(\tilde{e}_iM) = 0$. Then as above $\tilde{f}_i(\tilde{e}_iM) \cong \tilde{f}_i(\tilde{e}_iM) \cong M$ and so $\tilde{e}_iM \cong \tilde{e}_i^{\vee}M$ yielding $\text{jump}_i(\tilde{e}_i^{\vee}M) = 0$ which is a contradiction. So we must have $\text{jump}_i(\tilde{e}_iM) > 0$. Then by Proposition 6.6, $\varepsilon_i^{\vee}(\tilde{e}_iM) = \varepsilon_i^{\vee}(\tilde{f}_i\tilde{e}_iM) = \varepsilon_i^{\vee}(M) = c$.

For part (iii), first suppose $\varepsilon_i(\overline{M}) \geq c - \text{wt}_i(\overline{M})$. Then by part (ii) $\varepsilon_i^{\vee}(\tilde{e}_iM) = c = \varepsilon_i(M)$. In other words $\varepsilon_i^{\vee}(\tilde{e}_iM) = \varepsilon_i^{\vee}(\tilde{f}_i\tilde{e}_iM)$ so by Proposition 7.1 applied to $\tilde{e}_iM$,
\begin{equation}
\tilde{f}_i(\tilde{e}_i^{\vee})^c \tilde{e}_iM \cong (\tilde{e}_i^{\vee})^c \tilde{f}_i\tilde{e}_iM \cong (\tilde{e}_i^{\vee})^c M \cong \overline{M}.
\end{equation}
Hence $(\tilde{e}_i^{\vee})^c \tilde{e}_iM \cong \tilde{e}_iM$.

Next suppose $\varepsilon_i(\overline{M}) < c - \text{wt}_i(\overline{M})$. Then by part (iii)
\begin{equation}
\varepsilon_i^{\vee}(\tilde{e}_iM) = c - 1 = \varepsilon_i^{\vee}(M) - 1.
\end{equation}
In other words $\varepsilon_i^{\vee}(\tilde{f}_i\tilde{e}_iM) = \varepsilon_i^{\vee}(\tilde{e}_iM) + 1$, so by Proposition 7.1 applied to $\tilde{e}_iM$,
\begin{equation}
\tilde{e}_i^{\vee}M \cong \tilde{e}_i^{\vee} \tilde{f}_i\tilde{e}_iM \cong \tilde{e}_iM,
\end{equation}
\begin{equation}
(\tilde{e}_i^{\vee})^c \tilde{e}_iM \cong (\tilde{e}_i^{\vee})^c \tilde{e}_iM \cong (\tilde{e}_i^{\vee})^c \cong \overline{M}.
\end{equation}

Proposition 7.3. For each $i \in I$ define a map
$$
\Psi_i: B \rightarrow B \otimes B_i
$$
$$
M \mapsto (\tilde{e}_i^{\vee})^c(M) \otimes b_i(-c),
$$
where $c = \varepsilon_i^{\vee}(M)$. Then $\Psi_i$ is a strict embedding of crystals.

Proof. First we show that $\Psi_i$ is a morphism of crystals. (M1) is obvious. For (M2) let $\overline{M} = (\tilde{e}_i^{\vee})^c M$. We compute
\begin{equation}
\text{wt}(\psi(M)) = \text{wt}(\overline{M} \otimes b_i(-c)) = \text{wt}(\overline{M}) + \text{wt}(b_i(-c)) = \text{wt}(M) + c\alpha_i - c\alpha_i = \text{wt}(M).
\end{equation}
Consider first the case $j \neq i$. By Proposition 6.2
\begin{align*}
\varepsilon_j(\psi(M)) &= \varepsilon_j(\overline{M} \otimes b_i(-c)) \\
&= \text{max} \{ \varepsilon_j(\overline{M}), \varepsilon_j(b_i(-c)) - \langle h_j, \text{wt}(\overline{M}) \rangle \} \\
&= \text{max} \{ \varepsilon_j(\overline{M}), -\infty \} = \varepsilon_j(\overline{M}) \\
&= \varepsilon_j(M).
\end{align*}
MAIN THEOREMS

In the case $j = i$, Proposition 7.2 (i) implies

\[
\varepsilon_i(\Psi_i(M)) = \varepsilon_i(M) \otimes b_i(-c) = \max\{\varepsilon_i(M), c - \text{wt}_i(M)\}
\]

\[
= \varepsilon_i(M).
\]

(7.15)

Since for both crystals, $\varphi_j(b) = \varepsilon_j(b) + \langle h_j, \text{wt}(b) \rangle$ it follows $\varphi_j(M) = \varphi_j(\Psi_i(M))$ for all $j \in I$.

It is clear that $\Psi_i$ is injective. We will prove a stronger statement than (M3) and (M4), namely $\Psi_i(\tilde{e}_j M) = \tilde{e}_j(\Psi_i(M))$ and $\Psi_i(f_j M) = f_j(\Psi_i(M))$ which will show $\Psi_i$ is not just a morphism of crystals, but since it is injective, $\Psi_i$ is a strict embedding of crystals.

Observe

\[
\tilde{e}_j(\Psi_i(M)) = \tilde{e}_j(M) \otimes b_i(-c) = \begin{cases} 
\tilde{e}_j M \otimes b_i(-c) & \text{if } \varphi_j(M) \geq \varepsilon_i(b_i(-c)) = c \\
\tilde{e}_j M \otimes b_i(-c + 1) & \text{if } \varphi_j(M) < c.
\end{cases}
\]

(7.16)

We first consider the case when $j = i$. If $\varepsilon_i(M) = 0$, then clearly $\varepsilon_i(M) = 0$ and further $\tilde{e}_i M = \tilde{e}_i M = 0$. By Proposition 7.2 (i)

\[
\varepsilon_i(M) = 0 = \varepsilon_i(M) = \max\{\varepsilon_i(M), c - \text{wt}_i(M)\} \geq c - \text{wt}_i(M),
\]

(7.17)

yielding $\varphi_i(M) = \varepsilon_i(M) + \text{wt}_i(M) \geq (c - \text{wt}_i(M)) + \text{wt}_i(M) = c$, so by (4.8), (4.10) we get

\[
\tilde{e}_i \Psi_i(M) = \tilde{e}_i M \otimes b_i(-c) = 0 = \Psi_i(0) = \Psi_i(\tilde{e}_i M).
\]

(7.18)

Now suppose $\varepsilon_i(M) > 0$. Using that $\varphi_i(M) := \varepsilon_i(M) + \text{wt}_i(M)$, (4.8), and (4.10), Proposition 7.2 implies we can rewrite

\[
\tilde{e}_i \Psi_i(M) = \begin{cases} 
(\tilde{e}_i \vee) \varepsilon_i M \otimes b_i(-c) & \text{if } \varepsilon_i(M) \geq c - \text{wt}_i(M) \\
(\tilde{e}_i \vee) \varepsilon_i M \otimes b_i(-c + 1) & \text{if } \varepsilon_i(M) < c - \text{wt}_i(M)
\end{cases}
\]

(7.19)

\[
= (\tilde{e}_i \vee) \varepsilon_i(M) \otimes b_i(b_i(M))
\]

(7.20)

\[
= \Psi_i(\tilde{e}_i M).
\]

(7.21)

When $j \neq i$ note that $\varepsilon_i(\tilde{e}_j M) = \varepsilon_i(M) = c$ so long as $\tilde{e}_j M \neq 0$, by Proposition 6.2 applied to $\tilde{e}_j M$. Equation 5(i) of Proposition 7.1 implies $\tilde{M} = (\tilde{e}_i \vee) \varepsilon_j M = f_j(\tilde{e}_i \vee) \tilde{e}_j M$, so $\tilde{e}_j \tilde{M} = (\tilde{e}_i \vee) \tilde{e}_j M$. Therefore, by (7.16) as $\varepsilon_j(b_i(-c)) = -\infty$,

\[
\tilde{e}_j(\Psi_i(M)) = \tilde{e}_j M \otimes b_i(-c) = (\tilde{e}_i \vee) \tilde{e}_j M \otimes b_i(-c) = \Psi_i(\tilde{e}_j M).
\]

(7.22)

In the case $\tilde{e}_j M = 0$, Proposition 6.2 implies $\tilde{e}_j(\tilde{M}) = 0$ as well, so we compute

\[
\tilde{e}_j(\Psi_i(M)) = \tilde{e}_j M \otimes b_i(-c) = 0 = \Psi_i(0) = \Psi_i(\tilde{e}_j M).
\]

The proof that $\Psi_i(f_j M) = f_j(\Psi_i(M))$ is similar.

\[\square\]

7.2 Main Theorems

**Theorem 7.4.** The crystal $B$ is isomorphic to $B(\infty)$.
Proof. Recall that by abuse of notation, for irreducible modules $M$, we write $M \in \mathcal{B}$ as shorthand for $[M] \in \mathcal{B}$. We show that the crystal $\mathcal{B}$ satisfies the characterizing properties of $B(\infty)$ given in Proposition 4.3. Properties (B1)-(B4) are obvious with $\mathbf{1}$ the unique node with weight zero. The embedding $\Psi_i: \mathcal{B} \to \mathcal{B} \otimes B_i$ for (B5) was constructed in the previous section. (B6) follows from the definition of $\Psi_i$ as $\varepsilon_i^\vee(M) \geq 0$ for all $M \in \mathcal{B}, j \in I$. For (B7) we must show that for $M \in \mathcal{B}$ other than $\mathbf{1}$, there then exists $i \in I$ such that $\Psi_i(M) = N \otimes f_i^n b_i$ for some $N \in \mathcal{B}$ and $n > 0$. But every such $M$ has $\varepsilon_i^\vee(M) > 0$ for at least one $i \in I$, so that $N$ can be taken to be $\tilde{\varepsilon}_i^\vee(n)$ for $n = \varepsilon_i^\vee(M) > 0$. 

Now we will show the data $(\mathcal{B}^\Lambda, \varepsilon_i^\vee, \varphi_i^\Lambda, \tilde{\varepsilon}_i^\Lambda, \varepsilon_i^\Lambda, \text{wt}^\Lambda)$ of Section 5.3 defines a crystal graph and identify it as the highest weight crystal $B(\Lambda)$.

**Theorem 7.5.** $\mathcal{B}^\Lambda$ is a crystal; furthermore the crystal $\mathcal{B}^\Lambda$ is isomorphic to $B(\Lambda)$.

**Proof.** Proposition 8.2 of Kashiwara [Kas95] gives us an embedding

$$\Upsilon^\infty: B(\Lambda) \to B(\infty) \otimes T_\Lambda$$

(7.23)

which identifies $B(\Lambda)$ as a subcrystal of $B(\infty) \otimes T_\Lambda$. The nodes of $B(\Lambda)$ are associated with the nodes of the image

$$\text{Im} \Upsilon^\infty = \{ b \otimes t_\Lambda \mid \varepsilon_i^\vee(b) \leq \langle h_i, \Lambda \rangle, \quad \text{for all } i \in I \}$$

(7.24)

where $c = \varepsilon_i^\vee(b)$ is defined via $\Psi_i b = b' \otimes b_i(-c)$ for the strict embedding $\Psi_i: B(\infty) \to B(\infty) \otimes B_i$. The crystal data for $B(\Lambda)$ is thus inherited from that of $B(\infty) \otimes T_\Lambda$. Via our isomorphism $B(\infty) \otimes T_\Lambda \cong B \otimes T_\Lambda$ of Theorem (7.3) and the description of

$$\Psi_i: \mathcal{B} \to \mathcal{B} \otimes B_i$$

$$M \mapsto (\tilde{\varepsilon}_i^\vee)\varepsilon_i^\vee(M) M \otimes b_i(-\varepsilon_i^\vee(M))$$

(7.25)

the set

$$\{ M \otimes t_\Lambda \in \mathcal{B} \otimes t_\Lambda \mid \varepsilon_i^\vee(M) \leq \lambda_i, \quad \text{for all } i \in I \}$$

(7.26)

edowed with the crystal data of $\mathcal{B} \otimes T_\Lambda$ is thus isomorphic to $B(\Lambda)$.

Recall from Section 5.3 this is precisely $\text{Im} \Upsilon$, as $\varepsilon_i^\vee(M) \leq \lambda_i$ for all $i \in I$ if and only if $\text{pr}_\Lambda M \neq 0$ which happens if and only if $M = \text{inf}_\Lambda M$ for some $M \in \mathcal{B}^\Lambda$. By Kashiwara’s Proposition, we know $\text{Im} \Upsilon \cong B(\Lambda)$ as crystals.

What remains is to check that the crystal data $\text{Im} \Upsilon$ inherits from $\mathcal{B} \otimes T_\Lambda$ agrees with the data defined in Section 5.3 for $\mathcal{B}^\Lambda$. Once we verify this, we will have shown $\mathcal{B}^\Lambda$ is a crystal, $\mathcal{B}^\Lambda \cong B(\Lambda)$, and $\Upsilon$ is an embedding of crystals.

Let $M \in \mathcal{B}^\Lambda$. Recall, since $\text{pr}_\Lambda \text{inf}_\Lambda M \neq 0$, then $0 \leq \varphi_i^\Lambda(\text{inf}_\Lambda M) = \varphi_i^\Lambda(M)$ which was defined as $\max \{ k \mid \text{pr}_\Lambda \tilde{f}_i^k(\text{inf}_\Lambda M) \neq 0 \}$. We verify

$$\text{Cor } [6.21] \quad \varphi_i^\Lambda(\text{inf}_\Lambda M) = \varphi_i^\Lambda(M).$$

(7.27)

This computation, along with (5.11)–(5.14) completes the check that $(\mathcal{B}^\Lambda, \varepsilon_i^\vee, \varphi_i^\Lambda, \tilde{\varepsilon}_i^\Lambda, \varepsilon_i^\Lambda, \text{wt}^\Lambda)$ is a crystal and isomorphic to $B(\Lambda)$.
7.3 \(U_q^+\)-module structures

Set
\[
G_0^*(R) = \bigoplus_{\nu} G_0(R(\nu))^* \quad G_0^*(R^\Lambda) = \bigoplus_{\nu} G_0(R^\Lambda(\nu))^*
\]
where, by \( V^* \) we mean the linear dual \( \text{Hom}_A(V,A) \). Because \( G_0(R) \) and \( G_0(R^\Lambda) \) are \( \mathcal{A}U_q^+ \)-modules, we can endow \( G_0^*(R) \), \( G_0^*(R^\Lambda) \) with a left \( \mathcal{A}U_q^+ \)-module structure in several ways, via a choice of anti-automorphism. Here we denote by * the \( \mathcal{A} \)-linear anti-automorphism defined by
\[
e_i^* = e_i \quad \text{for all } i \in I.
\]
Specifically, for \( y \in \mathcal{A}U_q^+ \), \( \gamma \in G_0^*(R) \) or \( G_0^*(R^\Lambda) \), and \( N \) simple, set
\[
(y \cdot \gamma) ([N]) = \gamma (y^*[N])
\]
where we will identify \( e_i^* \) with \( e_i \).

\( G_0(R(\nu))^* \) has basis given by \( \{ \delta_M \mid M \in B, \text{wt}(M) = -\nu \} \) defined by
\[
\delta_M([N]) = \begin{cases} 
q^{-r} & M \cong N\{r\} \\
0 & \text{otherwise},
\end{cases}
\]
where \( N \) ranges over simple \( R(\nu) \)-modules. We set \( \text{wt}(\delta_M) = -\text{wt}(M) \). Likewise \( G_0(R^\Lambda(\nu))^* \) has basis \( \{ \delta_M \mid M \in B^\Lambda, \text{wt}(M) = -\nu + \Lambda \} \) defined similarly. Note that if \( \delta_M \) has degree \( d \) then \( \delta_M(1) = q^{-1}\delta_M \) has degree \( d - 1 \). Recall \( 1 \in B \) denotes the trivial \( R(0) \)-module and we will also write \( 1 \in B^\Lambda \) for the trivial \( R^\Lambda(0) \)-module.

Lemma 7.6.

i) \( e_i^{(m)} \cdot \delta_1 = \delta_{L(i^m)} \in G_0(R(mi))^* \); \( e_i^{(m)} \cdot \delta_1 = 0 \in G_0(R^\Lambda(mi))^* \subseteq G_0^*(R^\Lambda) \) if \( m \geq \lambda_i + 1 \).

ii) \( G_0^*(R) \) is generated by \( \delta_1 \) as a \( \mathcal{A}U_q^+ \)-module; \( G_0^*(R^\Lambda) \) is generated by \( \delta_1 \) as a \( \mathcal{A}U_q^+ \)-module.

**Proof.** The first part follows since \( e_i^{(m)}L(i^m) \cong 1 \) and the only irreducible module \( N \) for which \( e_i^{(m)}N \) is a nonzero \( R(0) \)-module is \( N \cong L(i^m)\{r\} \) for some \( r \in \mathbb{Z} \). Recall \( \text{pr}_\Lambda L(i^m) = 0 \) if and only if \( m \geq \lambda_i + 1 \).

For the second part, recall 1 co-generates \( G_0(R) \) (resp. \( G_0(R^\Lambda) \)) in the sense that for any irreducible \( M \), there exist \( i_t \in I \) such that
\[
e_i^{(m_k)} \cdots e_i^{(m_2)} e_i^{(m_1)} M \cong a1,
\]
where \( m_t = e_t(e_t^{-1} e_t^{-1} \cdots e_t^{-1} M) \) and \( a \in A \) (in fact \( a = q^r \) for some \( r \in \mathbb{Z} \)). So certainly \( \delta_1 \) generates \( G_0^*(R) \) (resp. \( \delta_1 \) generates \( G_0^*(R^\Lambda) \)).

More specifically, an inductive argument relying on “triangularity” with respect to \( \varepsilon_i \) gives \( \delta_M \in \mathcal{A}U_q^+ \cdot \delta_1 \) and \( \delta_M \in \mathcal{A}U_q^+ \cdot \delta_1 \).

**Lemma 7.7.**

i) The maps
\[
\mathcal{A}U_q^+ \xrightarrow{\varepsilon} G_0^*(R) \quad \mathcal{A}U_q^+ \xrightarrow{\varepsilon} G_0^*(R^\Lambda)
\]
\[
y \mapsto y \cdot \delta_1
\]
are \( \mathcal{A}U_q^+ \)-module homomorphisms.
ii) \( F \) and \( \mathcal{F} \) are surjective.

iii) \( \ker \mathcal{F} \ni e_i^{(\lambda_i+1)} \) for all \( i \in I \).

**Proof.** To show \( F \), \( \mathcal{F} \) are \( \mathcal{A} \mathcal{U}_q^+ \)-maps, we need only check the Serre relations (6.16) vanish on \( G_0^*(R), \ G_0^*(R^\Lambda) \). But as the corresponding operators are invariant under \( * \) and vanish on any \( [N] \), they certainly kill any \( \delta_M, \ \varnothing_M \).

Now \( F \) (resp. \( \mathcal{F} \)) is clearly surjective as it contains the generator \( \delta_i \) (resp. \( \varnothing_1 \)) in its image.

The third statement follows from part (ii) of Lemma 7.6.

If \( V(\Lambda) \) is the irreducible highest weight \( U_q(\mathfrak{g}) \)-module with highest weight \( \Lambda \) and highest weight vector \( v_\Lambda \) then its \( \mathcal{A} \)-form, or integral form, \( \mathcal{A}V(\Lambda) = \mathcal{A}U_q^+ \cdot v_\Lambda \). We let \( V(\Lambda)^* \) denote the graded dual of \( V(\Lambda) \), whose elements are sums of \( \delta_v, v \in V(\Lambda) \). If \( v \in V(\Lambda) \) has weight \( \mu \) then \( \delta_v \in V(\Lambda)^* \) has weight \(-\mu\) and \( e_i v \), if nonzero, has weight \( \mu + i \) in the notation of this paper. We set

\[
\mathcal{A}V^*(\Lambda) = \mathcal{A}U_q^+ \cdot \delta_{v_\Lambda}
\]

endowed with the left \( \mathcal{A}U_q^+ \)-module structure

\[
y \cdot \delta_v(w) = \delta_v(y^*w).
\]

Note that the \(-\mu\) weight space of the dual is the dual of the \( \mu \) weight space, and that both weight spaces are free \( \mathcal{A} \)-modules of finite rank.

As a left \( \mathcal{A}U_q^+ \)-module

\[
\mathcal{A}V^*(\Lambda) \cong \mathcal{A}U_q^+ / \sum_{i \in I} \mathcal{A}U_q^+ \cdot e_i^{(\lambda_i+1)}. \tag{7.30}
\]

**Theorem 7.8.** As \( \mathcal{A}U_q^+ \) modules

1. \( \mathcal{A}U_q^+ \cong G_0^*(R) \),
2. \( \mathcal{A}V^*(\Lambda) \cong G_0^*(R^\Lambda) \),
3. \( \mathcal{A}V(\Lambda) \cong G_0(R^\Lambda) \).

**Proof.** Note that both \( F \) and \( \mathcal{F} \) are surjective and preserve weight in the sense that \( \text{wt}(e_i) = i \) in the notation of this paper. We know the dimension of the \( \nu \) weight space of \( U_q^+ \) is

\[
|\{b \in B(\infty) \mid \text{wt}(b) = -\nu\}| = |\{M \in B \mid \text{wt}(M) = -\nu\}| = \text{rank}_A G_0(R(\nu)) = \text{rank}_A G_0(R(\nu))^*.
\]

Because \( \mathcal{A} \) is an integral domain, a surjection between two free \( \mathcal{A} \)-modules of the same (finite) rank must be an injection. Hence \( F \) must also be injective and hence an isomorphism.

Since the left ideal \( \sum_{i \in I} \mathcal{A}U_q^+ \cdot e_i^{(\lambda_i+1)} \) is contained in the kernel of \( \mathcal{F} \) by part iii of Lemma 7.7, \( \mathcal{F} \) induces a surjection

\[
\mathcal{A}V^*(\Lambda) \to G_0^*(R^\Lambda).
\]
The dimension of the $-\Lambda + \nu$ weight space of $V(\Lambda)^*$ is the same as
\[
\dim V(\Lambda)_{-\nu} = |\{ b \in B(\Lambda) \mid \text{wt}(b) = \Lambda - \nu\}| = |\{ M \in B^\Lambda \mid \text{wt}(M) = \Lambda - \nu\}| \tag{7.31}
\]
\[
= \text{rank}_{A} G_0(R^\Lambda(\nu))^* = \text{rank}_{A} G_0(R^\Lambda(\nu))^*, \tag{7.32}
\]
so as above, $\mathcal{F}$ must in fact be an isomorphism.

The third statement follows from dualizing with respect to the antiautomorphism $\ast$.

We note that [KL09] proves a stronger statement than part 1 of Theorem 7.8, namely that $A_f \cong K_0(R)$ as $A$-bialgebras. So in particular, as $A_{U_q^+}$-modules, $A_{U_q^+} \cong K_0(R)$. Using their result yields another proof that $A_{V(\Lambda)} \cong G_0(R^\Lambda)$ as $A_{U_q^+}$-modules. Using similar methods to theirs, one should also be able to give an alternate proof that $A_{V(\Lambda)} \cong G_0(R^\Lambda)$ as $A_{U_q^+}$-modules.
