Abstract

Interleukin-17 (IL-17) producing T helper cells (Th17) comprise a newly recognized T cell subset with an emerging role in adaptive immunity to a variety of fungi. Whether different airborne fungi trigger a common signaling pathway for Th17 induction, and whether this ability is related to the inherent pathogenic behavior of each fungus is currently unknown. Here we show that, as opposed to primary pathogenic fungi (Histoplasma capsulatum), opportunistic fungal pathogens (Aspergillus and Rhizopus) trigger a common innate sensing pathway in human dendritic cells (DCs) that results in robust production of IL-23 and drives Th17 responses. This response requires activation of dectin-1 by the fungal cell wall polysaccharide b-glucan that is selectively exposed during the invasive growth of opportunistic fungi. Notably, unmasking of b-glucan in the cell wall of a mutant of Histoplasma not only abrogates the pathogenicity of this fungus, but also triggers the induction of IL-23 producing DCs. Thus, b-glucan exposure in the fungal cell wall is essential for the induction of IL-23/Th17 axis and may represent a key factor that regulates protective immunity to opportunistic but not pathogenic fungi.

Introduction

In recent years, opportunistic fungal pathogens have become major causes of life-threatening infections in an expanding population of severely immunocompromised individuals, as a result of the increasing use of transplantation, the development of immunosuppressive therapies for autoimmune and neoplastic diseases, and the AIDS pandemic [1,2]. In these patients, Aspergillus is the predominant fungal pathogen [3], whereas Zygomycetes have emerged as the second most common cause of opportunistic mold infections [4,5]. Infections caused by these fungi have a poor prognosis with mortality rates exceeding 90% upon dissemination, mainly because of their inherent resistance to existing antifungal agents [1–5]. Thus, there is a need for better understanding of the pathogenesis of opportunistic fungal infections in order to develop novel therapeutic strategies.

Th helper (Th17) cells play a crucial role in host defense against fungi through the secretion of distinct cytokine profiles [6,7]. Traditionally, responses by interferon-γ (IFN-γ)-producing Th1 cells are considered to confer protective immunity against fungi, whereas Th17 responses mediated by IL-4 lead to increased susceptibility to fungal infections [6,7]. More recently, a subset of Th17 cells, called IL-17-producing Th17 (Th17-17) cells, have been identified and implicated in mucosal immunity against extracellular bacteria [8,9] and fungi [10-17]. In particular, IL-17 receptor deficient mice are susceptible to disseminated [10] and oropharyngeal [11] candidiasis, whereas impaired IL-17 production has been associated with increased susceptibility to fungal pneumonia caused by Pneumocystis [12], Cryptococcus [13], and Aspergillus [14]. In humans, patients with mutations in STAT3 have selective impairment of IL-17 producing T cells and are prone to infections with invasive fungal pathogens, including Candida and Aspergillus [15]. Furthermore, Candida-specific human memory CD4+ T cells belong to the Th17 subset [16], and are significantly decreased in patients with chronic mucocutaneous candidiasis [17].

IL-23, a member of the IL-12 cytokine family, has a master role in regulating Th17 development [8,9,18]. Dendritic cells (DCs) are the main source of IL-23, which is secreted as a heterodimer comprising of a p19 subunit and a p40 subunit shared with IL-12 [18]. Human Th17 cells originate from CD161+ T-cell precursors that constitutively express IL-23R [19], and naive CD4+ T cells differentiate in vivo into mature Th17 cells in response to the combined activity of IL-23 and IL-1b in the presence of TGF-β [19–22].

In contrast to IL-23, IL-12 is associated with the differentiation of naive CD4+ T cell into IFN-γ secreting Th1 cells [8,9,18].
Much effort has focused on identifying microbial ligands and the receptors that drive the differentiation of DCs into producers of either IL-12 or IL-23 [9,23]. In fungi, activation of members of the Toll-like receptor (TLR) family, mainly TLR2 and TLR4, in DCs has been linked to the induction of IL-12 leading to protective $T_{H}$1 responses against Candida and Aspergillus [24,25]. On the other hand, activation of $\text{dectin-1}$, a C-type lectin expressed on DCs that recognizes the polysaccharide b-glucan, triggers the induction of IL-23 through the syk-CARD-9 signaling pathway [26], and drives robust $T_{H}$17 response [26]. Interestingly, while the yeast form of Candida albicans induces IL-12, the invasive, tissue-infiltrating form of the fungus (hyphae) selectively induces IL-23 and drives $T_{H}$17 responses [26]. Therefore, it appears that tissue invasion by fungi triggers activation of the IL-23/$T_{H}$17 pathway that has a central role in the initiation of an acute inflammatory response via neutrophil recruitment and the induction of epithelial antimicrobial peptides [6,7]. The important role of $\text{dectin-1}$-syk-CARD-9 signaling in induction of $T_{H}$17 responses and protective mucosal immunity against Candida has been convincingly shown both in mice [27,28] and recently in humans [29,30].

In view of the complexity and the structural differences in the fungal cell wall of fungi [31,32], whether activation of $\text{dectin-1}$ signaling is a major pathway for $T_{H}$17 induction in response to airborne opportunistic fungal pathogens that currently cause the majority of fungal infections in immunocompromised patients, and whether this ability is related to specific growth stages and/or the inherent pathogenic behavior of each fungus is currently unknown.

Here we studied human DC responses against the two predominant airborne opportunistic fungal pathogens, Aspergillus and Rhizopus, and the pathogenic fungus Histoplasma. Importantly, we found that opportunistic fungal pathogens (Aspergillus and Rhizopus) but not primary pathogenic fungi (Histoplasma) prime dendritic cells (DCs) to produce high levels of IL-23, which drives $T_{H}$17 responses. The induction of these IL-23 producing DCs depended on activation of $\text{dectin-1}$ and is mediated by b-glucan exposed in the cell wall of the invasive form of opportunistic fungal pathogens. By contrast, the yeast form of the pathogenic fungus Histoplasma, which lacks cell wall exposure of b-glucan, failed to induce IL-23 producing DCs. Notably, unmasking of b-glucan in the cell wall of a mutant of Histoplasma, which lacks cell wall exposure of b-glucan, failed to induce IL-23 producing DCs. Interestingly, abundant staining of b-glucan in the cell wall of histoplasma failed to elicit IL-23 producing DCs (Figure 1A). Together, these data demonstrate that the invasive form of opportunistic fungal pathogens Aspergillus or Rhizopus but not of the pathogenic fungus Histoplasma drives the induction of IL-23 producing DCs.

The invasive form of opportunistic fungal pathogens but not that of primary pathogenic fungi exposes b-glucan in the cell wall surface

b-glucan has been shown to be a key driver of IL-23 production in DCs [23,26]. Previous studies have shown that Aspergillus exposes b-glucan on the cell wall surface during the invasive stage of growth (hyphae) [33–35]. Thus, we sought to determine whether like Aspergillus also Rhizopus but not Histoplasma exposes b-glucan in the cell wall of the invasive stage of fungal growth. Immunofluorescence studies using a b-glucan specific monoclonal antibody confirmed the exposure of b-glucan in hyphae of Aspergillus (Figure 2). Interestingly, abundant staining of b-glucan was also found on the surface of hyphae of Rhizopus (Figure 2), which is in contrast to previous reports that failed to identify b-glucan on the cell wall of Rhizopus and instead suggested that chitin and chitosan comprise the main polysaccharides of this fungus [36]. Importantly, there was no evidence of b-glucan staining in the hyphae of both opportunistic fungal pathogens and in the yeast form of the pathogenic fungus Histoplasma (Figure 2). These data indicate that b-glucan exposure selectively occurs in the invasive stage of growth of opportunistic fungal pathogens but not in primary pathogenic fungi, a finding that correlates with the ability of these fungi to induce IL-23 producing DCs.

Induction of IL-23 producing DCs by opportunistic fungal pathogens is $\text{dectin-1}$ dependent and is mediated by b-glucan

Next, we sought to demonstrate that the selective exposure of b-glucan in the hyphae of opportunistic fungal pathogens drives the induction of IL-23 producing DCs. We used laminarin, a competitive inhibitor of b-glucan for its binding to $\text{dectin-1}$, as a control, we stimulated DCs with the TLR4 agonist LPS, and showed that laminarin had no effect on the production of IL-23 by DCs (Figure S2). Furthermore, pre-incubation of DCs with a neutralizing anti-$\text{dectin-1}$ antibody resulted in complete inhibition of IL-23 production in DCs infected with hyphae of both opportunistic fungi, while it had no
effect on IL-23 production by DCs stimulated with LPS (Figure 3B).

Because b-glucan is not the only ligand of dectin-1 [37,38], we further investigated the role of b-glucan surface exposure by specific enzymatic digestion of b-glucan in the fungal cell walls using b-glucanase. The ability of b-glucanase to digest b-glucan in the cell wall of hyphae of Aspergillus and Rhizopus was confirmed by immunolourescence studies (Figure 3C). DCs infected with b-glucanase-treated hyphae were unable to produce any IL-23 (Figure 3D), indicating that hyphae of opportunistic fungal pathogens induce IL-23 producing DCs through b-glucan surface exposure.

Enforced b-glucan surface exposure in the non-pathogenic Histoplasma Δags1 mutant drives IL-23 producing DCs

In contrast to opportunistic fungal pathogens, in Histoplasma cell wall immunostimulatory b-glucans are covered in the yeast (infectious) form of the fungus by a layer of α-(1–3)-glucan [32,39]. Concealing of b-glucan by non-stimulatory α-(1–3)-glucan molecules is regarded as a virulence mechanism, because it allows Histoplasma to avoid immune recognition and survive within the host cells. As a proof of principle, b-glucan surface exposure in the Δags1 mutant of Histoplasma capsulatum that lacks α-(1–3)-glucan, renders it non-pathogenic in mice and results in increased release of TNFα in infected mouse macrophages through dectin-1 activation [39].

We hypothesized that similar to the induction of IL-23 release by b-glucan exposure in the hyphae of opportunistic fungal pathogens, unmasking of b-glucan in the Δags1 mutant of Histoplasma should trigger the release of IL-23 in human DCs. We initially confirmed by immunolourescence studies that the yeast form of the Δags1 mutant of Histoplasma had surface exposure of b-glucan as opposite to its isogenic complementary Δags1/+ strain (Figure 4A). Importantly, infection of human DCs with the yeast form of the Δags1 mutant of Histoplasma resulted in the production of IL-23 (Figure 4B); in contrast, there was no IL-23 production in DCs infected with the isogenic complementary Δags1/+ strain of Histoplasma (Figure 4B). Additionally, IL-23 production by human DCs infected with the Δags1 mutant was inhibited following blocking of dectin-1 receptor or enzymatic digestion of b-glucan (Figure 4B). These results further support the role of b-glucan in driving IL-23 producing DCs and indicate that the exposure of cell wall b-glucans may restrict the pathogenic potential of fungi via the induction of the IL-23–Th17 response pathway.

IL-23 producing DCs induced by opportunistic fungal pathogens drive Th17 responses

Because IL-23 producing DCs represent the key drivers of Th17 responses (8, 9, 19, 23), we next sought to determine whether human DCs stimulated with opportunistic fungal pathogens are capable of driving Th17 responses. Purified human naive and memory CD4+ T cells were activated polyclonally in the presence of supernatants of DCs previously stimulated with hyphae or spores of Aspergillus. DCs stimulated with hyphae but not spores of Aspergillus induced a predominant increase in IL-17 production compared to spores (mean increase from 4.6% to 9.7%; n = 5 experiments; P = 0.004) and IL-17/IFN-γ double positive CD4+ T cells (mean increase from 1.1% to 9.7%; n = 5 experiments; P = 0.002) (Figure S4).

Figure 1. The invasive stage of growth of opportunistic fungal pathogens but not that of primary pathogenic fungi drives the induction of IL-23 producing DCs. IL-23 (A) and IL-12 (B) produced by human monocyte-derived DCs (1×10⁶ cells per ml) following overnight stimulation with purified b-glucan (curdlan, 100 μg/ml), LPS (100 ng/ml), resting (spores) or invasive (hyphae) stages of growth of each opportunistic fungal pathogen (Aspergillus and Rhizopus) and the invasive form (yeast) of the pathogenic fungus Histoplasma, at a 1:1 ratio. The results are representative of 6 independent experiments. * indicates that the measured value was below the detection limit of the assay (<20 pg/ml). Error bars represent SD. *, P<0.001, paired Student’s t test.

doi:10.1371/journal.pone.0012955.g001
T<sub>h</sub>-17 responses by human DCs are typically driven by IL-23, but may also require, in particular at the initial stages of differentiation other pro-inflammatory cytokines, including IL-1β or IL-1β plus IL-6 [19–23]. We found that IL-23 producing DCs also secreted large amounts of IL-1β, which was dependent on activation of dectin-1 as it was completely abolished in the presence of dectin-1 neutralizing antibody (Figure S3A). In addition, IL-6 was also produced by IL-23 producing DCs, although its secretion was only partially dependent on activation of dectin-1 (Figure S3B). Notably, there was no significant reduction in IL-6 production by

Figure 3. Induction of IL-23 producing DCs by opportunistic fungal pathogens is dectin-1 dependent and is mediated by β-glucan. (A) IL-23 production by human monocyte-derived DCs pre-incubated for 1 h with increasing concentrations of the dectin-1 inhibitor laminarin (0, 0.01, 0.1, and 1 mg/ml) and subsequently stimulated with hyphae of either *Aspergillus* (open cycles) or *Rhizopus* (closed cycles), at a 1:1 ratio. (B) IL-23 production by DCs stimulated with hyphae of either *Aspergillus* (black bars) or *Rhizopus* (white bars), or β-glucan (scattered bars) or LPS (gray bars) alone or following 1 h pre-incubation with an anti-dectin-1 blocking antibody (10 μg/ml). Data are expressed as mean ± SEM values for DCs derived from three different donors. (C) Representative confocal microscopy images of β-glucan surface staining in hyphae of *Aspergillus* or *Rhizopus* untreated or following overnight enzymatic digestion with β-glucanase (10 U/ml). (D) IL-23 production by DCs stimulated with hyphae of *Aspergillus* (white bars) or *Rhizopus* (black bars) untreated or following overnight enzymatic digestion with β-glucanase. Data shown are representative of 3 independent experiments. Error bars represent SD. *, P<0.001, paired Student’s t test.

doi:10.1371/journal.pone.0012955.g003
The addition of neutralizing antibodies against IL-23 inhibited IL-17 production by naïve and memory CD4+ T cells polarized with Aspergillus-stimulated DCs close to the baseline levels (Figure 5C). Importantly, neutralizing antibodies against IL-23 did not affect IFN-γ production by CD4+ T cells polarized with Aspergillus-stimulated DCs (Figure 5C). Therefore, IL-23 producing DCs induced by hyphae of opportunistic fungi drive TH17 responses.

**Discussion**

The emergence of life-threatening infections caused by airborne opportunistic fungal pathogens in an expanding population of non-neutropenic patients with defects in T-cell function, such as transplant recipients, patients with autoimmune diseases receiving biologic therapies or corticosteroids, and individuals with AIDS [1,2], illustrates the pivotal role of adaptive immunity in antifungal host defense.

Recent studies in mice demonstrate that the newly identified TH17-IL23 axis regulates epithelial host defense against a growing list of fungi [10–14]. In view of the considerable differences in generation and function of TH17 cells between mice and humans [8,9], understanding the regulatory mechanisms for induction of antifungal TH17 responses in humans is important for development of targeted therapeutic strategies. Although purified b-glucan acts as a potent adjuvant for the induction of IL-23 producing DCs and TH17 priming [26], the structural complexity and differential cellular composition of various fungi makes it difficult to predict whether, and how common molecular patterns in cell wall of different fungi link innate sensing by DCs with TH17 pathway induction. Herein, we identified a common innate sensing pathway in human DCs that is triggered by opportunistic fungi. We found that this pathway was dependent on activation of \( \text{dectin-1} \) signaling by b-glucan exposure in the hyphae of opportunistic fungal pathogens, and resulted in robust induction of IL-23 producing DCs that primed TH17 antifungal responses. Importantly, we also demonstrated that pathogenic fungi evade \( \text{TH17} \) induction by concealing immunostimulatory b-glucans with other polysaccharide layers and thus avoiding activation of \( \text{dectin-1} \) signaling.

Our initial studies identified that the signature cytokine of the TH17 pathway, IL-23, was selectively produced by human DCs infected with hyphae of \( \text{Aspergillus} \) or \( \text{Rhizopus} \), by not by DCs infected with dormant spores of opportunistic fungi or the yeast form of the pathogenic fungus \( \text{Histoplasma} \). Importantly, we found that generation of these IL-23 producing DCs correlated with b-glucan surface exposure in the hyphae of \( \text{Aspergillus} \) and \( \text{Rhizopus} \). This was an unexpected finding based on biochemical studies that failed to identify b-glucan in the cell wall of \( \text{Rhizopus} \) (36), and clinical evidence of lack of detectable amounts of b-glucan release in human infections caused by this fungus [4,5]. Our results corroborate with recent studies that identified b-glucan synthetase, the enzyme responsible for synthesis of b-glucan, in \( \text{Rhizopus} \) [40]. Next, by using specific \( \text{dectin-1} \) inhibitors and b-glucan enzymatic digestion, we confirmed that induction of IL-23 producing DCs is dependent on activation of \( \text{dectin-1} \) signaling and is mediated by b-glucan exposure in the hyphae of opportunistic fungi. Importantly, surface exposure of b-glucan in the \( \text{Ags1} \) mutant of \( \text{Histoplasma} \) that lacks the upper layer of a-glucan, not only abrogated its virulence, but also triggered the induction of IL-23 producing DCs via activation of \( \text{dectin-1} \) signaling.

Our study is the first to explore the interaction of DCs with fungi of the class Zygomycetes and the regulatory mechanisms of TH17 induction against airborne opportunistic fungi in humans.
Figure 5. IL-23 producing DCs induced by opportunistic fungi drive Th17 responses. (A) IL-17 and IFN-γ production determined by ELISA in memory T cell cultures primed for 5 d in plates coated with anti-CD3 and anti-CD28, in the presence of supernatants (sups) of unstimulated DCs, or sups of DCs stimulated with either *Aspergillus* spores, or hyphae (above plots), and then re-stimulated for 24 h with anti-CD3 and anti-CD28. Data are expressed as mean ± SEM values for DCs derived from six different donors. (B) Intracellular cytokine staining for IL-17 and IFN-γ in memory CD4+ T cells primed and expanded as described in (A), and re-stimulated for 5 h with PMA and ionomycin. (C) ELISA of IL-17 and IFN-γ in 24-hour culture supernatants (sups) of naive and memory CD4+ T cells primed for 5 d in plates coated with anti-CD3 and anti-CD28, in the presence of sups of unstimulated DCs or *Aspergillus* spores-stimulated DCs, or *Aspergillus* hyphae-stimulated DCs alone or in the presence of neutralizing anti-IL-23 antibodies. Data shown are representative of 5 independent experiments. Error bars represent SD. *, P<0.001, paired Student’s t test. doi:10.1371/journal.pone.0012955.g005
In agreement to our findings, a recent study reported that dormant spores of *Aspergillus* were immunologically inert and did not induce DC or alveolar macrophage activation, because of the presence of a surface 'rodlet layer', composed of the hydrophobic RodA protein that masks underlying immunostimulatory molecules [41].

Previous studies suggested that coordinated activation of TLR-2 and TLR-4 by *Aspergillus* spores triggers a T<sub>1</sub><sub>H</sub>-1 protective response, whereas *Aspergillus* hyphae trigger TLR-2 activation and a T<sub>1</sub><sub>H</sub>-2 response [6,24]. Nonetheless, studies using different TLR and MYD88 knockout mice failed to convincingly show increased susceptibility to *Aspergillus* infection in the absence of immunosuppression [7]. In contrast, *dectin-1* knockout mice, display increased susceptibility to invasive aspergillosis without the need for administration of immunosuppressive agents, significantly attenuated proinflammatory response and decreased IL-17 production in the lung [14]. Notably, in agreement to our finding, macrophages from *dectin-1* knockout mice fail to produce proinflammatory cytokines in response to *Aspergillus* infection [14]. Nonetheless, we cannot preclude that other immunostimulatory molecules on the fungal cell wall are selectively exposed during invasive fungal growth to trigger PRRs in human DCs [42–44]. Likewise, collaborative activation of *dectin-1* with surface TLRs and/or other PRR may be implicated in innate sensing of different opportunistic fungi [45,46].

The induction of IL-23 producing DCs by different microbial ligands is a key driver of T<sub>1</sub><sub>H</sub>-17 responses [8,9,19,23]. The ability of *dectin-1* when compared to other PRRs for preferentially induction of IL-23 over IL-12, may be related to activation of a noncanonical NF-kappaB signaling pathway mediated by the serine-threonine kinase Raf-1 [47]. Indeed, supernatants from IL-23 producing DCs generated by stimulation with *Aspergillus* hyphae or b-glucan induced the production of IL-17 in naive human CD4<sup>+</sup> T cells and a robust expansion of IL-17 producing memory human CD4<sup>+</sup> T cells stimulated polyclonally. Notably, IL-17 production was significantly reduced by an antibody neutralizing IL-23, as also suggested by other studies [19,21–23].

Overall, our studies demonstrate the important role of *dectin-1* signaling as a major innate sensing pathway for induction on T<sub>1</sub><sub>H</sub>-17 antifungal responses in humans. It is plausible that dysregulation of this pathway in patients with underlying immunodeficiency leads to unrestricted growth of opportunistic fungi and the development of life-threatening infections. Therefore, targeting this pathway for immunotherapy is an appealing strategy for prevention and treatment of patients at increased risk for development of opportunistic fungal infections. Future studies on the function of *dectin-1/T<sub>1</sub>H-17* axis in immunocompromised individuals might also provide a tool for risk stratification for development of fungal infections.

**Materials and Methods**

**Reagents**

Highly purified *Escherichia coli* LPS, laminarin from *Laminaria digitata*, and b-1,3-D-glucanase from *Helix pomatia* were obtained from Sigma-Aldrich (St. Louis, MO). Purified particulate b-glucan (curdian) was from Waiko (Tokyo, Japan). b-1,3-glucan-specific monoclonal antibody was from Biosupplies (Parkville, Australia). Blocking monoclonal antibodies for *dectin-1* (MAB1839, clone 259931; 10 μg/ml) and appropriate isotype control antibodies were from R&amp;D Biosystems. Neutralizing antibodies for the IL-23 p19 subunit (AF1716; 10 μg/ml), and IL-4 (34019; 10 μg/ml) were from R&amp;D Biosystems. Neutralizing antibodies for IFN-γ (B27; 10 μg/ml) were from BD Biosciences.

**Microorganisms and culture conditions**

The *Aspergillus fumigatus* strain AF293 and the *Rhizopus oryzae* clinical isolate 557969 were grown on YAG-chloramphenicol agar plates for 3 days at 37°C. Fungal spores in the presence of sterile 0.1% Tween 20 in PBS were harvested by gentle shaking, washed, filtered, counted by a hemacytometer, and suspended at a concentration of 10<sup>6</sup> spores/ml. Germinating hyphae of *Aspergillus* and *Rhizopus* were obtained following growth in liquid RPMI 1640 media in a shaking incubator (220 rpm, 37°C), for 12 h and 8 h, respectively. Typically, >80% of conidia of each fungus were visibly swollen after 5 h.

Enzymatic digestion of b-glucan in the hyphae of *Aspergillus* and *Rhizopus* was performed by using b-1,3-D-glucanase from *Helix pomatia* (Sigma). Hyphae of both fungi were incubated overnight in a shaking bath with 10 U/ml of b-glucanase at a temperature of 55°C and pH 5, 0. Inactivation of enzyme was achieved by 10 min incubation at 100°C followed by three washes in PBS. Verification of b-glucan digestion was performed by immunostaining with a b-glucan monoclonal antibody.

*H. capsulatum* *Agb1* mutant and its isogenic complementary strain *Agb1* (+) were derived from the clinical isolate G186A (ATCC 26029) and have been described in ref 39. *Histoplasma* yeasts were grown at 37°C with 95% air/5% CO<sub>2</sub> in HMM supplemented with 100 μg/ml uracil. Dispersed *Histoplasma* yeasts were obtained by growth of liquid cultures to late exponential phase, removal of large yeast clumps by low-speed centrifugation (60 s at 100×g), three washes with Ham’s F-12 (Invitrogen, Carlsbad, CA), and counting with a hemacytometer.

Inactivation of fungi was done by heat exposure (30 min, 65°C) or exposure to 1% paraformaldehyde (4°C, overnight). In initial DC stimulation experiments, amphotericin B (1 μg/ml) was added to the cell cultures immediate after infection with fungi to prevent germination or restrict overgrowth of germinating hyphae. Because there were no appreciable differences in cytokine production as compared to infection of DCs with inactivated fungi, all following studies were performed with inactivated fungal cells.

**Generation of monocyte-derived DCs**

This study was approved by the Institutional Review Board for human research at the M. D. Anderson Cancer Center in Houston. Separation of peripheral blood mononuclear cells (PBMCs) was performed by density gradient centrifugation using ficoll hypaque (Amersham Pharmacia Biotech, Uppsala, Sweden) from healthy donor blood obtained from the Gulf Coast Regional Blood Center, Houston, Texas. CD14<sup>+</sup> cells were enriched from the PBMCs using CD14 microbeads and columns (Miltenyi Biotec, Auburn, CA). In order to generate DCs, CD14<sup>+</sup> cells were cultured in the presence of IL-4 (100 ng/ml; R&amp;D Systems, Minneapolis, MN) and granulocyte-macrocytrophage colony-stimulating factor (GM-CSF; 100 ng/ml; R&amp;D Systems, Minneapolis, MN) for 5 days at 2×10<sup>6</sup> cells/ml in RPMI 1640 supplemented with 5% fetal bovine serum (FBS; v/v). On day 3 the cells were 70 to 90% CD1a<sup>+</sup> and 95% CD14<sup>+</sup>. Then the culture medium containing IL-4 and GM-CSF was replaced with culture medium alone 2 h before infection with fungi or other treatments.

**Purification of naive and memory CD4<sup>+</sup> T lymphocytes from adult blood**

Untouched naive and memory CD4<sup>+</sup> T lymphocytes were purified from PBMCs by immunomagnetic depletion with the...
naive CD4+ T Cell Isolation Kit II and memory CD4+ T Cell Isolation Kit (Miltenyi Biotec), respectively. Naive CD4+ T cells (CD3+CD4+CD56-CD16-CD11c-) typically had a purity of over 95%, as evidenced by flow cytometry. For some experiments, peripheral blood CD4+ T cells were isolated with the CD4+ T Cell Isolation Kit II (Miltenyi Biotec), followed by staining with APC-CD45RO+, FITC-CD45RA+, PE-Cy5-CD4+, and PE-labeled lineage mixture antibodies against CD8α, CD14, CD16, CD19, CD56, CD11c, γδ-TCR, CD11c, CD25, and BDCA-2, and sorted into two fractions of CD4+CD45RO-CD45RA+ and CD4+CD45RA-CD45RO+ with cell purity over 99%, on a FACSAria (BD Biosciences).

Stimulation of monocyte-derived DCs
Monocyte-derived DCs were seeded at a final concentration of 10⁶ cells per ml in RPMI culture medium in flat-bottomed 24-well plates (Falcon). Spores or hyphae of each opportunistic fungus or yeast cells of each strain of Histoplasma were counted, and added to DC cultures at a final concentration of 10⁶ cells per ml (1:1 E:T ratio). In order to normalize for the amount of spores and hyphae that were co-cultured with DCs and minimize the effects of the increased fungal biomass of hyphae, we used early germinating hyphae (fig 2) instead of mature, branching hyphae. In pilot experiments, increasing the amount of dormant spores to 1:10 or 1:20 didn’t have a significant effect on the type and amount of pro-inflammatory cytokines produced by DCs. Stimulation of DCs was also induced in flat-bottomed 24-well plates by adding purified b-glucan (curdlan; 100 μg/ml), or LPS (100 ng/ml). For receptor blocking experiments DCs were pre incubated with blocking antibodies for dectin-1, or the corresponding isotype control antibody for 1 h before treatment with fungi or other stimuli.

T cell stimulation
Naive and memory CD4+ T cell subsets were cultured in flat-bottomed 96-well plates (Falcon) in Yssel’s medium supplemented with 2 mM l-glutamine (GIBCO-Invitrogen), 1 mM sodium pyruvate (GIBCO-Invitrogen), 10 mM HEPES (GIBCO-Invitrogen), 100 U/ml penicillin, 100 μg/ml streptomycin (GIBCO-Invitrogen), and 10% FCS (v/v; GIBCO-Invitrogen), at a density of 5x10⁵ cells per well, and stimulated with plate-bound anti-CD3 (10 μg/ml) and soluble anti-CD28 (1 μg/ml) in the presence of supernatants from unstimulated or variably stimulated monocyte-derived DCs. For some experiments with naive CD4+ T cells, anti-IFN-γ and anti-IL-4 were added to the cultures at a concentration of 10 μg/ml. After 5–6 days cells were collected and washed extensively and their viability was determined by trypan blue exclusion. Cells (1x10⁵ cells/ml) were restimulated with PMA (50 ng/ml; Sigma) and Ionomycin (500 ng/ml; Sigma) for 6 h (for flow cytometry intracellular staining) or in the presence of anti-CD3 and anti-CD28 for 24 h (for ELISA).

Analysis of cytokine production
Supernatants of stimulated DCs or T cells were collected after overnight culture. Cytokine levels in the supernatants were determined by using ELISA kits for human IL-1β, IL-6, IL-12, IL-17, IFN-γ (R&D systems), and IL-23 ELISA (eBioscience) according to the manufacturer’s instructions. Cells producing IFN-γ and IL-17 were analyzed by intracellular cytokine staining after the addition of GolgiStop (10 μg/ml; BD Biosciences) during the final 4 h of incubation. Cells were made permeable with Cytofix/Cytoperm reagents (BD Biosciences). Cells were stained with FITC-anti-IFN-γ (4S.B3; BD Pharmingen) and PE-anti-IL-17 (eBio 64DEC17; eBioscience) and washed and then were analyzed by flow cytometry (FACS Calibur; BD Biosciences).

Confocal imaging studies
Live spores or hyphae of opportunistic fungi and yeast cells of Histoplasma were fixed with 4% paraformaldehyde, pelleted in propylene tubes, washed twice with PBS, blocked for 30 min in PBS plus 1% goat serum, incubated for 1 h with a mouse monoclonal antibody to linear-(1,3)-b-glucan (Biosupplies; 1 μg/ml), washed twice in PBS plus 1% goat serum and stained by a secondary Alexa Fluor 488 goat anti-mouse Ab (Molecular probes). Images of PFA-fixed fungal cells were acquired using a Leica SP2 RS laser-scanning confocal microscope with an oil-immersion objective (Leica ×63/1.4 numerical aperture) using identical gain settings at room temperature. The Alexa Fluor 488 goat anti-mouse Ab used as fluorochrome was excited with an Argon Laser. Images were collected using LCS V2.61 software (Leica Microsystems, GmbH) and processed with Adobe Photoshop CS2.

Statistics
A standard two-tailed t-test or a t-test with Welch’s correction was applied for statistical analysis by using the GraphPad Prism software. P values of 0.05 or less were considered significant.

Supporting Information

Figure S1 TH-17 polarizing cytokines are preferentially induced by fungal hyphae in human DCs. IL-1β (A) IL-6 (B) and TNF-a produced by human monocyte-derived DCs (1x10⁶ cells per ml) following overnight stimulation with purified b-glucan (curdlan, 100 μg/ml), resting (spores) or invasive (hyphae) stages of growth of each opportunistic fungus (Aspergillus and Rhizopus) at a 1:1 ratio. Data are expressed as mean ± SEM values for DCs derived from three different donors. *, P<0.001; paired Student’s t test. Found at: doi:10.1371/journal.pone.0012955.s001 (1.08 MB TIF)

Figure S2 Dectin-1 inhibitor laminarin has no effect on DC activation by TLR ligands. IL-23 production by human monocyte-derived DCs pre incubated for 1 h with increasing concentrations of the dectin-1 inhibitor laminarin (0, 0.01, 0.1, and 1 mg/ml) and subsequently stimulated with LPS (100 ng/ml). Data shown are representative of 2 independent experiments. Found at: doi:10.1371/journal.pone.0012955.s002 (3.21 MB TIF)

Figure S3 TH-17 polarizing cytokines are preferentially induced by fungal hyphae in human DCs. IL-1β (A), IL-6 (B), and IL-12 (C) production by DCs stimulated with hyphae of Aspergillus (white bars) or Rhizopus (black bars), or b-glucan (scattered bars) or LPS (gray bars) with (+) or without (−) pre incubation for 1 h with an anti-decit-1 blocking antibody (10 μg/ml). Data are expressed as mean ± SEM values for DCs derived from three different donors. *, P<0.001; **, P<0.05 paired Student’s t test. Found at: doi:10.1371/journal.pone.0012955.s003 (4.87 MB TIF)

Figure S4 Aspergillus hyphae drive the expansion of IL-17 producing memory CD4+ T cells. Flow cytometry to determine the percentage of cells producing IL-17 and IFN-γ among memory CD4+ T cells primed for 5 d in plates coated with anti-CD3 and anti-CD28, in the presence of supernatants of unstimulated DCs, or supernatants of DCs stimulated with either Aspergillus spores, or hyphae (above plots), and re-stimulated for 5 h with PMA and Ionomycin. Data are expressed as mean ± SEM values for DCs derived from five different donors. Found at: doi:10.1371/journal.pone.0012955.s004 (4.54 MB TIF)

Figure S5 Polymyxin B has no effect in IL-6 production by DCs activated with b-glucan or fungal hyphae. IL-6 production by DCs stimulated with hyphae of Aspergillus (white bars) or b-glucan (black bars scattered bars) or LPS (gray bars) with or without pre incubation for 10 min with increasing concentrations of polymyx-
in B (PMX-B; 0, 10, 100 μg/ml). Data shown are representative of 2 independent experiments.
