Tangent of K-theory

Benjamin Hennion*

April 18, 2019

Abstract

We show that the relative algebraic K-theory functor fully determines the absolute cyclic homology over any field $k$ of characteristic 0. More precisely, we prove that the tangent of K-theory, in terms of (abelian) deformation problems over $k$, is cyclic homology. As a consequence, any structure on K-theory is inherited by cyclic homology.

We also show that the Loday-Quillen-Tsygan generalized trace comes as the tangent morphism of the canonical map $BGL_k \to K$ mapping a vector bundle to its class in K-theory.

The proof builds on results of Goodwillie, using Wodzicki’s excision for cyclic homology and formal deformation theory à la Lurie-Pridham.

Introduction

Computing the tangent of algebraic K-theory has been the content of many articles. The first attempt known to the author is due to Spencer Bloch [Blo] in 1973. It was then followed by a celebrated article of Goodwillie [Goo] in 1986.

*IMO - Université d’Orsay, Paris 11 - benjamin.hennion@u-psud.fr
Considering the following example, we can easily forge an intuition on the matter. Let $A$ be a smooth commutative $\mathbb{Q}$-algebra and $G$ be the algebraic group $G = [\text{GL}_x, \text{GL}_x]$. The group $G(A)$ admits a universal central extension

$$1 \longrightarrow K_2(A) \longrightarrow G(A)^+ \longrightarrow G(A) \longrightarrow 1$$

by the second $K$-theory group of $A$. The group $G(A)^+$ is the Steinberg group of $A$. Looking now at the tangent Lie algebra $\mathfrak{g}$ of $G$, its current Lie algebra $\mathfrak{g}(A) := \mathfrak{g} \otimes_{\mathbb{Q}} A$ also admits a universal central extension, this time by the first cyclic homology group

$$0 \longrightarrow HC_1^Q(A) \longrightarrow \mathfrak{g}(A)^+ \longrightarrow \mathfrak{g}(A) \longrightarrow 0.$$

The obvious parallel between those two central extensions leads to the idea that the (suitably considered) tangent of $K$-theory should be cyclic homology.

In both the aforementioned articles of Bloch and Goodwillie, the tangent is considered in a rather naive sense: as if $K$-theory was an algebraic group. Bloch defines the tangent of $K$-theory at $0$ in $K(A)$ (for $A$ a smooth commutative algebra over $\mathbb{Q}$) as the fiber of the augmentation

$$K(A[\varepsilon]) \to K(A),$$

where $\varepsilon$ squares to $0$. Goodwillie then extends and completes the computation by showing that relative (rational) $K$-theory is isomorphic to relative cyclic homology, in the more general setting where $A$ is a simplicial associative $\mathbb{Q}$-algebra. He shows that for any nilpotent extension $A'$ of $A$, the homotopy fiber of $K(A') \otimes \mathbb{Q} \to K(A) \otimes \mathbb{Q}$ and of $HC_1^Q(A') \to HC_1^Q(A)$ are quasi-isomorphic.

One can then show using Goodwillie's result that stable rational $K$-theory should be cyclic homology.

In this article, we give another definition of the tangent of $K$-theory using deformation theory, over any field $k$ containing $\mathbb{Q}$. We then show that this tangent equivalent to the absolute cyclic homology. Before explaining exactly how this tangent is defined, let us state the main result precisely. Even though our theorem holds for any field $k$, we will in this introduction restrict for simplicity to the connective case\(^1\) (or equivalently to the case of simplicial algebras). With our definition of tangent, for any unital simplicial $k$-algebra $A$, we have

$$\mathcal{T}_{K(A),0} \simeq HC_{-1}^k(A)$$

where the right-hand-side denotes the (shifted) $k$-linear (absolute) cyclic homology of $A$. Of course, for this to hold for any field $k$, the left-hand side has to depend on $k$. This dependence occurs by only considering relative $K$-theory of nilpotent extensions $A'$ of $A$ of the form $A' = A \otimes_k B \to A$, where $B$ is a (dg-)Artinian commutative $k$-algebra with residue field $k$. The defines a functor

$$K(A_\lambda) : \text{dgArt}_k \to \text{Sp}_{\geq 0}$$

$$B \mapsto \text{hofib}(K(A \otimes_k B) \to K(A))$$

from the category of dg-Artinian commutative $k$-algebra with residue field $k$ to the category of connective spectra. The category of such functors $\text{dgArt}_k \to \text{Sp}_{\geq 0}$ admits a full subcategory of formal deformation problems – ie of functors satisfying a Schlessinger condition (see Definition 2.1.1). The datum of such a functor is now equivalent to the datum of a complex of $k$-vector spaces. The induced fully faithful functor $\text{dgMod}_k \to \text{Fct}(\text{dgArt}_k, \text{Sp}_{\geq 0})$ admits a left adjoint – denoted $\ell Ab$ – that forces the Schlessinger conditions.

We define the tangent of $K$-theory (of $A$) as

$$\mathcal{T}_{K(A),0} := \ell Ab(K(A_\lambda))$$

and our main theorem now reads

---

\(^1\)For the unbounded case, we essentially replace in what follows $A \otimes_k B$ with its connective cover $(A \otimes_k B)^{<0}$. 

2
**Theorem 1** (see Corollary 3.1.3). Let $A$ be any (H-)unital dg-algebra over $k$, with char$(k) = 0$. There is a natural equivalence

$$ H^{-\bullet}(T_{K(A),0}) \simeq HC_{-1}^k(A). $$

As a consequence, the K-theory functor fully determines the cyclic homology functors over all fields of characteristic 0. Moreover, it gives its full meaning to the use of “Abelian K-theory” as a name of cyclic homology.

The above equivalence is furthermore compatible with the $\lambda$-operations on each side, and any other structure K-theory may have would be immediately transported onto cyclic homology.

Using our theorem, we then prove (assuming $A$ is connective) that the canonical natural transformation $BGL_\infty \to K$ induces a morphism $gl_x(A) \to HC^k_{-1}(A)$ of homotopical Lie algebras (i.e. a $L_x$-morphism). Such a morphism corresponds to a morphism of complexes

$$ CE^k(A_{gl_x}) \to HC^k_{-1}(A) $$

from the Chevalley-Eilenberg homological complex to cyclic homology. We will show that this morphism identifies with the Loday-Quillen-Tsygan generalized trace.

**Structure of the proof**

The proof of Theorem 1 goes as follows. First, we show in subsection 2.3 that the tangent $T_{K(A),0}$ only depends on the (relative) rational K-theory functor $K \wedge Q$. Using the work of Goodwillie [Goo], we know the relative rational K-theory functor is equivalent (through the Chern character), with the relative rational cyclic homology functor: $K \wedge Q \simeq HC_{-1}^k$. We get

$$ T_{K(A),0} := \ell^Q(\tilde{K}(A)) \simeq \ell^Q(HC_{-1}^Q(A)) $$

where $HC_{-1}^Q(A)$: $dgArt_k \to dgMod^Q_{0}$ maps an Artinian dg-algebra $B$ over $k$ to the connective Q-dg-module $hofib(HC_{-1}^Q(A \otimes_k B) \to HC_{-1}^Q(A))$, and where $\ell^Q$ is the left adjoint of the fully faithful functor $dgMod_k \to Fct(dgArt_k, dgMod^Q_{0})$ mapping $V$ to $B \mapsto (V \otimes_k Aug(B))_{\leq 0}$.

Since cyclic homology is well defined for non-unital algebras, we also have a functor $HC_{-1}^Q(\tilde{A}_A)$ mapping an Artinian $B$ to the (shifted) cyclic homology of the augmentation ideal $A \otimes_k Aug(B)$.

We then argue that the functor $\ell^Q$ is (non-unital) symmetric monoidal (once restricted to a full subcategory, see Proposition 2.3.9). Since $\ell^Q(A \otimes_k Aug(-)) = A$, this implies the equivalence $\ell^Q HC_{-1}^Q(\tilde{A}_A) \simeq HC_{-1}^k(A)$.

We will then prove (see Theorem 3.1.1) that the induced morphism

$$ \ell^Q HC_{-1}^Q(\tilde{A}_A) \simeq \ell^Q HC_{-1}^k(A) $$

is a quasi-isomorphism. We use here the assumption that $A$ is unital (or at least H-unital). This excision statement is close to Wodzicki’s excision theorem for cyclic homology [Wod]. The structure of our proof relies on a paper by Guccione and Guccione [GG], where the authors give an alternative proof of Wodzicki’s theorem. Nonetheless, our Theorem 3.1.1 is strictly speaking not a consequence of Wodzicki’s theorem, and the proof is somewhat more subtle.

Composing those quasi-isomorphisms, we find the announced theorem

$$ T_{K(A),0} := \ell^Q(\tilde{K}(A)) \simeq \ell^Q(HC_{-1}^Q(A)) \simeq \ell^Q(HC_{-1}^Q(\tilde{A}_A)) \simeq HC_{-1}^k(A). $$

**Possible generalizations**

In this article, we work (mostly for simplicity) over a field $k$ of characteristic 0. The results will also hold over any commutative $Q$-algebra, or, more generally, over any eventually coconnective simplicial $Q$-algebra.\[^2\]

\[^2\]so that the theory of formal moduli problems would still work flawlessly.
A more interesting generalization would be to (try to) work over the sphere spectrum. Since we only need in what follows 'abelian' formal moduli problems, it is not so clear that the characteristic 0 is necessary. There would, however, be significant difficulties to be overcome, starting with a Wodzicki’s excision theorem for topological cyclic homology.

Acknowledgements
The question answered in this text naturally appeared while working on [FHk] with G. Faonte and M. Kapranov. A discussion with G. Ginot and M. Zeinalian raised the problem dealt with in our last section. I thank them for the many discussions we had, that led to this question. I also thank D. Calaque, P-G. Plamondon and M. Robalo for many useful discussion on the content of this article.

Notations
From now on, we fix the following notations

- Let $k$ be a field of characteristic 0.
- Let $\text{dgMod}_k$ denote the category of (cohomologically graded) complexes of $k$-vector spaces. Let $\text{dgMod}^{\leq 0}_k$ be its full subcategory of connective objects (ie $V^n = 0$ for $n > 0$). Let $\text{dgMod}_k$ and $\text{dgMod}^{\leq 0}_k$ denote the $\infty$-categories obtained from the above by inverting the quasi-isomorphisms.
- Let $\text{dgAlg}^{\text{nu}}_k$ be the category of (possibly non-unital) associative algebras in $\text{dgMod}_k$ (with its usual graded tensor product). Denote by $\text{dgAlg}^{\text{nu},\leq 0}_k$ its full subcategory of connected objects. Denote by $\text{dgAlg}^{\text{nu},\leq 0}_k \subset \text{dgAlg}^{\text{nu}}_k$ the associated $\infty$-categories.
- For $A \in \text{dgAlg}^{\text{nu},\leq 0}_k$, we denote by $\text{dgBiMod}^{\text{nu},\leq 0}_A$ the category of connective $A$-complexes with a left and a right action of $A$. Denote by $\text{dgBiMod}^{\text{nu},\leq 0}_A$ its associated $\infty$-category.
- Let $\text{cdga}^{\leq 0}_k$ denote the category of connective commutative dg-algebras over $k$. We denote by $\text{cdga}^{\leq 0}_k$ its $\infty$-category.
- Let $\text{sSets}$ be the $\infty$-category of spaces, $\text{Sp}_{\geq 0}$ the $\infty$-category of connective spectra, and $\Sigma^\infty : \text{sSets} \to \text{Sp}_{\geq 0} : \Omega^\infty$ the adjunction between the infinite suspension and loop space functors.

1 Relative cyclic homology and K-theory
In this first section, we will introduce cyclic homology, K-theory and the relative Chern character between them. Most of the content has already appeared in the literature. The only original fragment is the extension of some of the statements and proofs to simplicial or dg-algebras (most notably Wodzicki’s excision Theorem 1.2.2, or the relative Volodin construction).

1.1 Hochschild and cyclic homologies
A) Definitions Fix an associative dg-algebra $A \in \text{dgAlg}^{\text{nu}}_k$. Assuming (for a moment) that $A$ is unital, its Hochschild homology is

$$\text{HH}^k(A) = A \otimes_{A \otimes_k A^*} A.$$
It comes with a natural action of the circle, and we define its cyclic homology $\mathcal{H}_c^k(A)$ to be the (homotopy) coinvariants $\mathcal{H}_c^k(A)_{hS^1}$ under this action. To define those homologies for a non-unital algebra $A$, we first formally add a unit to $A$ and form $A^+ \cong A \oplus k$. We then define $F(A) = \text{hocolim}(k \to F(A^+))$ for $F$ being either $\mathcal{H}_c^k$ or $\mathcal{H}_c^k$. Those definitions turn out to agree with the former ones when $A$ was already unital.

Unfortunately, we will need later down the road a construction of $\mathcal{H}_c^k(A)$ for $A$ non-unital that does not rely on the one for unital algebra. We will therefore work with the following explicit models.

We fix $A \in \text{dgAlg}_{k}^{nu}$ a (non necessarily unital) associative algebra in complexes over $k$. We also fix $M$ an $A$-bimodule. Throughout this section, the tensor product $\otimes$ will always refer to the tensor product over $k$.

**Definition 1.1.1.** We call the (augmented) Bar complex of $A$ with coefficient in $M$ and denote by $\mathcal{B}_c^k(A,M)$ the $\oplus$-total complex of the bicomplex

$$
\cdots \to M \otimes A_{\otimes 2} \rightarrow M \otimes A \rightarrow M \rightarrow 0
$$

with $M$ in degree 0 and with differential $-b': M \otimes A_{\otimes n} \to M \otimes A_{\otimes n-1}$ given on homogeneous elements by

$$
b'(a_0 \otimes \cdots \otimes a_n) = \sum_{i=0}^{n-1} (-1)^{\epsilon_i} a_0 \otimes \cdots \otimes a_i a_{i+1} \otimes \cdots \otimes a_n
$$

where $\epsilon_i = i + \sum_{j<i} |a_j|$ (where $|a|$ standing for the degree of the homogeneous element $a$). One easily checks that $b'$ squares to 0 and commutes with the internal differentials of $A$ and $M$.

We denote by $\mathcal{B}_c^k(A)$ the complex $\mathcal{B}_c^k(A,M)$.

Assuming $A$ is unital and the right action of $A$ on $M$ is unital, we can build a nullhomotopy of $\mathcal{B}_c^k(A,M) \approx 0$. This contractibility does not hold for general non-unital algebras and modules.

**Definition 1.1.2** (Wodzicki). The dg-algebra $A$ as above is called H-unital if $\mathcal{B}_c^k(A) \approx 0$. The $A$-bimodule $M$ is called H-unitary over $A$ if $\mathcal{B}_c^k(A,M) \approx 0$.

**Remark 1.1.3.** In the above definitions, we only used the right action of $A$ on $M$. In the original article of Wodzicki, such a module $M$ would be called right H-unitary. A similar notion exists for left modules.

**Remark 1.1.4.** If $A$ is H-unital, then its right module $M \otimes A$ if H-unitary, for any $M$. Indeed, we then have $\mathcal{B}_c^k(A,M \otimes A) \approx M \otimes \mathcal{B}_c^k(A) \approx 0$.

**Definition 1.1.5.** We denote by $\mathcal{H}_c^k(A,M)$ the $\oplus$-total space of the bicomplex

$$
\cdots \to M \otimes A_{\otimes 2} \rightarrow b \to M \otimes A \rightarrow b \to 0
$$

with $M$ in degree 0 and with differential $b: M \otimes A_{\otimes n} \to M \otimes A_{\otimes n-1}$ given on homogeneous elements by

$$
b(a_0 \otimes \cdots \otimes a_n) = \sum_{i=0}^{n-1} (-1)^{\epsilon_i} a_0 \otimes \cdots \otimes a_i a_{i+1} \otimes \cdots \otimes a_n + (-1)^{(|a_n|+1)\epsilon} a_n a_0 \otimes \cdots \otimes a_{n-1}
$$

$$
= b'(a_0 \otimes \cdots \otimes a_n) + (-1)^{(|a_n|+1)\epsilon} a_n a_0 \otimes \cdots \otimes a_{n-1}.
$$

Here also, the differential squares to 0 and is compatible with the internal differentials of $A$ and $M$.

We denote by $\mathcal{H}_c^k(A)$ the complex $\mathcal{H}_c^k(A,M)$. 

5
If $A$ is (H-)unital, the complex $\mathcal{H}^k(A)$ is the usual Hochschild complex, that computes the Hochschild homology of $A$. For general $A$’s, we need to compensate for the lack of contractibility of the Bar-complex with some extra-terms.

Let $t, N: A^\otimes n+1 \rightarrow A^\otimes n+1$ by the morphisms given on homogeneous elements by the formulae

$$t(a_0 \otimes \cdots \otimes a_n) = (-1)^{(|a_0|+1)\cdot n}a_n \otimes a_0 \otimes \cdots \otimes a_{n-1} \quad \text{and} \quad N = \sum_{i=0}^n t^i.$$  

One easily checks that they define morphisms of complexes $1-t: B^k(A) \rightarrow \mathcal{H}^k(A)$ and $N: \mathcal{H}^k(A) \rightarrow B^k(A)$. Moreover we have $N(1-t) = 0$ and $(1-t)N = 0$. We can therefore define Hochschild and cyclic homology as follows.

**Definition 1.1.6.** We define the Hochschild homology $\text{HH}_k^k(A)$ and the cyclic homology $\text{HC}_k^k(A)$ of $A$ as the $\otimes$-total complexes of the following bicomplexes

$$\text{HH}_k^k(A): \quad \cdots \rightarrow 0 \rightarrow 0 \rightarrow B^k(A) \rightarrow 1-t \mathcal{H}^k(A) \rightarrow 0 \rightarrow \cdots$$

$$\text{HC}_k^k(A): \quad \cdots \rightarrow N B^k(A) \rightarrow 1-t \mathcal{H}^k(A) \rightarrow N B^k(A) \rightarrow 1-t \mathcal{H}^k(A) \rightarrow 0 \rightarrow \cdots$$

where in both cases, the rightmost $\mathcal{H}^k(A)$ is in degree 0. The Connes exact sequence is the obvious fiber and cofiber sequence

$$\text{HH}_k^k(A) \rightarrow \text{HC}_k^k(A) \rightarrow \text{HC}_k^k(A)[2]$$

induced by the above definitions.

**Remark 1.1.7.** The Hochschild homology of $A$ is the homotopy cofiber of $1-t: B^k(A) \rightarrow \mathcal{H}^k(A)$. In particular, we have a fiber (and cofiber) sequence

$$B^k(A) \rightarrow \mathcal{H}^k(A) \rightarrow \text{HH}_k^k(A).$$

If $A$ is H-unital, then we have $\mathcal{H}_k^k(A) \simeq \text{HH}_k^k(A)$. Moreover, under this assumption, using the reduced Bar complex as a resolution of $A$ as a $A \otimes A^n$-dg-module, we easily show:

$$\text{HH}_k^k(A) \simeq A \otimes_{A \otimes A^n} A.$$

**Remark 1.1.8.** The normalization $N$ can be seen as a map $N: \text{HH}_k^k(A) \rightarrow \text{HH}_k^k(A)[-1]$, which in turn is an action of (the $k$-valued homology of) the circle $S^1$ on $\text{HH}_k^k(A)$. Choosing a suitable resolution of $k$ as an $H_*(S^1) := H_*(S^1, k)$-module, we find

$$\text{HC}_k^k(A) = \text{HH}_k^k(A)_{hS^1} = \text{HH}_k^k(A) \otimes_{H_*(S^1)} k.$$  

**B) Relation to Chevalley-Eilenberg homology** Cyclic homology is sometimes referred to as abelian K-theory for the following reason: it is related to (the homology of) the Lie algebra $\mathfrak{gl}_x(A)$ of finite matrices the same way K-theory is related to (the homology of) the group $\text{GL}_x(A)$.

More specifically, for $A$ a dg-algebra, the generalized trace map is a morphism

$$\text{Tr}: \text{CE}_*^{k}(\mathfrak{gl}_x(A)) \rightarrow \text{HC}_*^k(A)[1]$$

used by Loday-Quillen [LQ] and Tsygan [Tsy] to prove (independently) the following statement for $A$ a discrete algebra, and by Burghelea [Bur] for general dg-algebras.
Theorem 1.1.9 (Loday-Quillen, Tsygan, Burghelea). When A is unital, the morphism $\text{Tr}$ induces an equivalence of Hopf algebras

$$\text{CE}_{\kappa}^k(gl_z(A)) \cong \text{Sym}_k(HC^k_A(1)),$$

where the product on the left-hand-side is given by the direct sum of matrices.

1.2 Filtrations, relative homologies and Wodzicki’s excision theorem

Definition 1.2.1. Let $f : A \to B$ be a map of (possibly non-unital) connective dg-algebras. The relative Hochschild (resp. cyclic) homology of A over B is the homotopy fiber

$$\bar{\text{HH}}^k(f) := \text{hofib}(\text{HH}^k(A) \to \text{HH}^k(B)) \quad (\text{resp. } \bar{\text{HC}}^k(f) := \text{hofib}(\text{HC}^k(A) \to \text{HC}^k(B))).$$

If I denotes the homotopy fiber of f endowed with its induced (non-unital) algebra structure, we have canonical morphisms

$$\eta_{\text{HH}} : \bar{\text{HH}}^k(I) \to \bar{\text{HH}}^k(f) \quad \text{and} \quad \eta_{\text{HC}} : \bar{\text{HC}}^k(I) \to \bar{\text{HC}}^k(f).$$

Theorem 1.2.2 (Wodzicki [Wod]). Let $I \to A \to B$ be an extension of (possibly non-unital) connective dg-algebras. If I is H-unital, then the induced sequences

$$\text{HH}^k(I) \longrightarrow \text{HH}^k(A) \longrightarrow \text{HH}^k(B)$$

$$\text{HC}^k(I) \longrightarrow \text{HC}^k(A) \longrightarrow \text{HC}^k(B)$$

are fiber and cofiber sequences. In other words, the canonical morphisms $\eta_{\text{HH}}$ and $\eta_{\text{HC}}$ are equivalences.

Strictly speaking, Wodzicki only proves the above theorem in the case where A, B and I are concentrated in degree 0. If his proof should be generalizable to connective dg-algebras, some computations seem to become tedious. Fortunately, Guccione and Guccione published in [GG] another proof of this result, that is very easily generalizable to connective dg-algebras.

We will actually not need Theorem 1.2.2 in what follows. We will, however, need to reproduce some steps of its proof in a more complicated situation. In this subsection, we will give a short proof of Theorem 1.2.2, where we have isolated the statements to be used later. The proof follows closely the work of [GG].

We fix $f : A \to B$ a degree-wise surjective morphism in $\text{dgAlg}_{k, un}^{m, n, \leq 0}$. We denote by I the kernel of f. Let $M \in \text{dgBiMod}_{A, k}^{m, n, \leq 0}$. We introduce a filtration on both $\mathcal{B}^k_A(I, M)$ and from $\mathcal{H}^k_A(I, M)$. Those filtrations were originally found in [GG].

A) A filtration from $\mathcal{B}^k_A(I, M)$ to $\mathcal{B}^k_A(A, M)$ and from $\mathcal{H}^k_A(I, M)$ to $\mathcal{H}^k_A(A, M)$

We introduce a filtration on both $\mathcal{B}^k_A(A, M)$ and $\mathcal{H}^k_A(A, M)$. Those filtrations were originally found in [GG].

Fix $n \in \mathbb{N}$. Let $p \in \mathbb{N}$. We set

$$M^p_n = \begin{cases} M \otimes A^p & \text{if } p \leq n \\ M \otimes A^{\leq n} \otimes I^{p-n} & \text{if } p > n. \end{cases}$$

We denote by $\mathcal{F}_A^p(f, M)$ (resp. $\mathcal{F}_A^p(f, M)$) the subcomplex of $\mathcal{B}^k_A(A, M)$ (resp. $\mathcal{H}^k_A(A, M)$) given as the total complex of the bicomplex

$$\begin{array}{ccccccc} \cdots & M^0_n & \xrightarrow{b'} & M^0_{n-1} & \xrightarrow{b'} & \cdots & M^0_1 & \xrightarrow{b'} & M^0_0 \rightarrow 0 \\ (\text{resp. } \mathcal{F}_A^p(f, M)) : & \cdots & M^p_n & \xrightarrow{b} & M^p_{n-1} & \xrightarrow{b} & \cdots & M^p_1 & \xrightarrow{b} & M^p_0 \rightarrow 0. \end{array}$$

For simplicity, we restrict ourselves to the connective case. The general case – unneeded for our purposes – would work similarly.
Remark 1.1.4.

Lemma 1.2.6. For any $F$ of set $W$ we define $I$ the complex $W = \text{ker} F$. We have $\text{B}_n(I) \simeq \text{colim}_n F(B)$. (resp. $H_n(I)$ is $H$-unitary as an $H$-module.)

Corollary 1.2.4. In particular, we have

$$ 0 \simeq \text{B}_n(I, M) \simeq \text{B}_n(A, M) \text{ and } \text{H}_n(I, M) \simeq \text{H}_n(A, M). $$

Corollary 1.2.5. Let $N$ be a connective left $B$-dg-module. If $I$ is $H$-unital then

$$ \text{H}_n(A, N \otimes I) \simeq \text{H}_n(I, N \otimes I) = \text{B}_n(I, N \otimes I) \simeq 0. $$

Proof. The first equivalence is an application of the above corollary. The equality follows from the trivial observation that the left action if $I$ on $N$ is trivial. The last equivalence is implied by fact that $I$ is $H$-unital, together with Remark 1.1.4.

B) A filtration from $\text{B}_n^k(A, B)$ to $\text{B}_n^k(B)$ and from $\text{H}_n^k(A, B)$ to $\text{H}_n^k(B)$ For $n, p \in \mathbb{N}$, we set

$$ N_p^n := \begin{cases} B^n \otimes B^{n+1} & \text{if } p \leq n \\ B^n \otimes A^{n+1} \otimes B^{-p} & \text{else.} \end{cases} $$

We define $Q_p^n(f)$ (resp. $Q_p^n(f)$) as the quotient of $B^k(A, B)$ (resp. of $\text{H}_n^k(A, B)$) given by

$$ Q_p^n(f): \cdots \to N_p^n \to N_{p-1}^n \to \cdots \to N_1^n \to N_0^n \to 0 $$

(resp. $Q_p^n(f): \cdots \to N_p^n \to N_{p-1}^n \to \cdots \to N_1^n \to N_0^n \to 0.$)

We have $Q_0^n(f) \simeq B_k^k(A, B)$ and $Q_0^n(f) \simeq H_k^k(A, B)$, as well as

$$ \text{colim}_n Q_p^n(f) \simeq B_k^k(B) \text{ and } \text{colim}_n Q_p^k(f) \simeq H_k^k(B). $$

Lemma 1.2.6. For any $n \in \mathbb{N}$, we have:

$$ \ker Q_p^n(f) \to Q_p^{n+1}(f) \simeq B_k^k(A, B^{n+1} \otimes I)[n + 1] $$

$$ \ker Q_p^n(f) \to Q_p^{n+1}(f) \simeq H_k^k(A, B^{n+1} \otimes I)[n + 1]. $$
Lemma 1.2.6

Theorem 1.2.2

and

Corollary 1.2.5

Corollary 1.2.4

, we deduce that

that the filtration from

The conclusion follows.

The other terms, for \( 0 \leq j \leq n \), are cancelled because of the vanishing of the composite \( I \to A \to B \).

Theorem 1.2.2

Proof. We have \( K^n_p := \ker(N^n_p \to N^{n+1}_p) \approx 0 \) if \( p \leq n \) and \( K^n_p \cong B^\otimes p \to A^\otimes p \to A \) else. The differential \( b' \) induces the differential \( K^n_{p+1} \to K^n_p \) given on a homogeneous tensor

by the formula

\[
\pm b_0 \otimes \cdots \otimes b_n \otimes i_{n+1} \otimes a_{n+2} \otimes \cdots \otimes a_{p+1} + \sum_{j=n+2}^p \pm b_0 \otimes \cdots \otimes b_n \otimes i_{n+1} \otimes a_{n+2} \otimes \cdots \otimes a_j \otimes \cdots \otimes a_{p+1}.
\]

Corollary 1.2.7. If \( I \) is \( H \)-unital, then

\[
B_k(I, B) \cong B_k(B) \quad \text{and} \quad H_k(A, B) \cong H_k(B).
\]

Proof. It follows from Lemma 1.2.6 and Corollary 1.2.5 that the filtration from \( H_k(A, B) \) to \( H_k(B) \) we just introduced is quasi-constant. The case of \( B_k \) is similar.

C) The proof of Theorem 1.2.2. We start with an extension \( I \to A \to B \) of connective dg-algebras. Up to suitable replacements, we can assume that \( f: A \to B \) is a degreewise surjective, and that \( I \) is its kernel. Consider the commutative diagram

\[
\begin{array}{ccc}
H_k(I) & \xrightarrow{\alpha} & H_k(A, I) \\
\downarrow & & \downarrow\beta \\
H_k(A) & \xrightarrow{\beta} & H_k(A, B) \\
\downarrow & & \downarrow \\
H_k(B)
\end{array}
\]

The functor \( H_k(A, -) \) preserves fiber sequences, and therefore the horizontal sequence is a fiber sequence. From Corollary 1.2.4 and Corollary 1.2.7, we deduce that \( \alpha \) and \( \beta \) are quasi-isomorphisms. In particular the diagonal sequence is a fiber sequence. Similarly, we show that the sequence

\[
B_k(I) \to B_k(A) \to B_k(B)
\]

is a fiber sequence. The result then follows from the definitions of \( \text{HH}_k \) and \( \text{HC}_k \).

D) Invariance under quasi-isomorphisms Let us record for future use that all the constructions of the previous paragraphs are well-behaved with respect to quasi-isomorphisms.

Lemma 1.2.8. The following statements hold.

(i) Let \( A \to A' \) be a quasi-isomorphism in \( \text{dgAlg}_k^{\geq 0} \) and let \( M_1 \to M_2 \) be a quasi-isomorphism of connective \( A' \)-bimodules. The induced morphisms

\[
B_k(A, M_1) \to B_k(A', M_1) \to B_k(A', M_2)
\]

and

\[
H_k(A, M_1) \to H_k(A', M_1) \to H_k(A', M_2)
\]

are quasi-isomorphisms. In particular, we have quasi-isomorphisms \( B_k(A) \to B_k(A', A') \) and \( H_k(A) \to H_k(A, A') \to H_k(A') \) as well as \( \text{HH}_k(A) \to \text{HH}_k(A', A') \) and \( \text{HC}_k(A) \to \text{HC}_k(A', A') \).

(ii) Let \( f: A \to B \) and \( g: A' \to B' \) be two fibrations in \( \text{dgAlg}_k^{\geq 0} \) and let \( A \to A' \) and \( B \to B' \) be two quasi-isomorphisms commuting with \( f \) and \( g \). Denote by \( I \) and \( I' \) the kernels of \( f \) and \( g \), respectively (so that the induced morphism \( I \to I' \) is a quasi-isomorphism too). Then
Remark 1.3.10. Goodwillie’s definition of relative $K$-theory and cyclic homology in \cite{Goo} differs from ours by a shift of 1.

The main result of \cite{Goo} states that the Chern character induces an equivalence $\tilde{\chi}: K \wedge Q \to \overline{HC}^k[1]$. In what follows, we will give a handy construction of the relative Chern character

$$\tilde{\chi}: K \wedge Q \to \overline{HC}^k[1].$$

This construction of $\tilde{\chi}$ a priori differs from the one given by Goodwillie, but they have been proven to coincide by Cortiñas and Weibel in \cite{CW} (see Remark 1.3.10 below).

In order to construct our relative Chern character, we will need some explicit model for relative $K$-theory of connective dg-algebras over $k$ (containing $Q$). For convenience, we will work with the equivalent model of simplicial $k$-algebras. We denote by $sAlg_k$ the category of simplicial (unital) algebras over $k$, endowed with its standard model structure.

1.3 Relative cyclic homology and $K$-theory

In this subsection, we recall the fundamental notions of $K$-theory and of the equivariant Chern character, at least in the relative setting.

We consider the (connective) $K$-theory functor as an $\infty$-functor $dgAlg_{\text{conn}}^k \to Sp_{\geq 0}$. Let $\text{dgAlg}_k^{\geq 0, \Delta^1_{\text{nil}}}$ denote the $\infty$-category of morphisms $A \to B$ that are surjective with nilpotent kernel at the level of $H^0$.

**Definition 1.3.1.** The relative $K$-theory functor is the $\infty$-functor

$$\bar{K}: \text{dgAlg}_{k}^{\geq 0, \Delta^1_{\text{nil}}} \to Sp_{\geq 0}$$

given on a morphism $f: A \to B$ by the homotopy fiber $\bar{K}(f) = \text{hofib}(K(A) \to K(B))$.

Since the map $H_0A \to H_0B$ is surjective with nilpotent kernel, the map $K_1(A) \to K_1(B)$ is also surjective while the map $K_0(A) \to K_0(B)$ is an isomorphism. In particular, the spectrum $\bar{K}(f)$ is connected.

**Definition 1.3.2.** The relative cyclic homology functor is the $\infty$-functor

$$\bar{HC}^k: \text{dgAlg}_{k}^{\geq 0, \Delta^1_{\text{nil}}} \to \text{dgMod}_{k}^\geq$$

given on $f: A \to B$ by $\bar{HC}^k_{\text{conn}}(f) := \text{hofib}(HC^k(A) \to HC^k(B))$.

**Remark 1.3.3.** Goodwillie’s definition of relative $K$-theory and cyclic homology in \cite{Goo} differs from ours by a shift of 1.

The main result of \cite{Goo} states that the Chern character induces an equivalence $\tilde{\chi}: K \wedge Q \to \overline{HC}^k[1]$. In what follows, we will give a handy construction of the relative Chern character

$$\tilde{\chi}: K \wedge Q \to \overline{HC}^k[1].$$

This construction of $\tilde{\chi}$ a priori differs from the one given by Goodwillie, but they have been proven to coincide by Cortiñas and Weibel in \cite{CW} (see Remark 1.3.10 below).
A) Matrix groups and K-theory  We start by recalling notions from [Wal] (see also [Goo]). For $A \in \mathrm{sAlg}_K$, we denote by $M_n(A)$ the simplicial set obtained by taking $n \times n$-matrices levelwise. Finally, we define the group of invertible matrices as the pullback

$$
\begin{array}{ccc}
\mathrm{GL}_n(A) & \longrightarrow & M_n(A) \\
\downarrow & & \downarrow \\
\mathrm{GL}_n(\pi_0 A) & \longrightarrow & M_n(\pi_0 A).
\end{array}
$$

We have $\pi_0(\mathrm{GL}_n(A)) \simeq \mathrm{GL}_n(\pi_0 A)$ and $\pi_i(\mathrm{GL}_n(A)) \simeq M_n(\pi_i A)$ for $i \geq 1$. In particular, this construction preserves homotopy equivalences. The simplicial set $\mathrm{GL}_n(A)$ is a group-like simplicial monoid and we denote by $\mathrm{BGL}_n(A)$ its classifying space. Finally, we denote by $\mathrm{BGL}(A)$ the increasing union $\bigcup_n \mathrm{BGL}_n(A)$.

Applying Quillen’s plus construction to $\mathrm{BGL}(A)$ yields to a model for K-theory, so that there is an equivalence

$$
K_0 \times \mathrm{BGL}(-) \overset{+}{\simeq} \Omega^\infty K.
$$

Based on this equivalence, we will build in the next paragraph a model for relative K-theory using relative Volodin spaces.

B) Relative Volodin construction  The Volodin model for the K-theory of rings first appeared in [Vol] in the absolute case. The relative version seems to originate from an unpublished work of Ogle and Weibel. It can also be found in [Lod]. We will need a version of that construction for simplicial algebras over $k$.

We fix a fibration $f : A \to B$ in $\mathrm{sAlg}_K$ such that the induced morphism $\pi_0(A) \to \pi_0(B)$ is surjective. In particular, the morphism $f$ is levelwise surjective. We denote by $I$ its kernel and we assume that $\pi_0 I$ is nilpotent in $\pi_0 A$.

**Definition 1.3.4.** Let $n \geq 1$ and let $\sigma$ be a partial order on the set $\{1, \ldots, n\}$. We denote by $T_\sigma^n(A, I)$ the subsimplicial set of $M_n(A)$ given in dimension $p$ by the subset of $M_n(A_p)$ consisting of matrices of the form $1 + (a_{ij})$ with $a_{ij} \in I_p$ if $i$ is not lower than $j$ for the order $\sigma$.

As a simplicial set, $T_\sigma^n(A, I)$ is isomorphic to a simplicial set of the form $A^\alpha \times I^\beta$ with $\alpha$ and $\beta$ are integers depending on $\sigma$, such that $\alpha + \beta = n^2$. In particular, this construction is homotopy invariant. Moreover, the map $T_\sigma^n(A, I) \to M_n(A)$ factors through $\mathrm{GL}_n(A)$. Actually, $T_\sigma^n(A, I)$ is a simplicial subgroup of the simplicial monoid $\mathrm{GL}_n(A)$.

**Definition 1.3.5.** We define the relative Volodin space $X(A, I)$ as the union

$$
X(A, I) := \bigcup_{n, \sigma} BT_\sigma^n(A, I) \subset \mathrm{BGL}(A).
$$

The group $\pi_1(X(A, I))$ contains as a maximal perfect subgroup the group $E(\pi_0(A))$ and we apply the plus construction to this pair.

**Proposition 1.3.6.** The inclusion $X(A, I) \to \mathrm{BGL}(A)$ induces a fiber sequence

$$
X(A, I)^+ \to \mathrm{BGL}(A)^+ \to \mathrm{BGL}(B)^+.
$$

In particular, we have a (functorial) equivalence

$$
X(A, I)^+ \simeq \Omega^\infty \tilde{K}(f).
$$
Proof. This is a classical argument, that can be found in [Lod, §11.3] for rings. We simply extend it to simplicial algebras. We start by drawing the following commutative diagram

\[
\begin{array}{ccc}
(a) & (b) & (c) \\
(1) & X(A,0) & X(A,I) & \Omega^g K(f) \\
& & \downarrow & \downarrow \\
(2) & X(A,0) & \text{BGL}(A) & \text{BGL}(A)^+ \\
& & \downarrow & \downarrow \\
(3) & 0 & \text{BGL}(B)^+ & \text{BGL}(B)^+. \\
\end{array}
\]

The space \(X(A,0)\) is acyclic (see [Sus] for the discrete case, the simplicial case being deduced by colimits). It follows (by the properties of the plus construction), that the raw (2) is a fibration sequence. Obviously, so are the raw (3) and the columns (a) and (c). It now suffices to show that column (b) is a fibration sequence. Consider the commutative diagram

\[
\begin{array}{ccc}
& & \\
X(A,I) & \rightarrow & \text{BGL}(A) & \rightarrow \text{BGL}(B)^+ \\
& \downarrow \tau & \downarrow p & \downarrow \\
X(B,0) & \rightarrow & \text{BGL}(B) & \rightarrow \text{BGL}(B)^+. \\
\end{array}
\]

The square \((\tau)\) is homotopy Cartesian. Indeed, the morphism \(p\) is induced by a pointwise surjective morphism of grouplike simplicial monoids (recall that we assumed \(\pi_0(I)\) to be nilpotent). It is therefore a fibration. We can now see that the diagram is cartesian on the nose by looking at its simplices. The bottom raw is a fibration sequence. It follows that the top raw (which coincides with column (b)) is also a fibration sequence.

As a consequence, raw (1) induces a fibration sequence in homology. Since \(X(A,0)\) is acyclic, the homologies of \(X(A,I)\) and of \(\Omega^g K(f)\) are isomorphic. It follows that \(X(A,I)^+\) and \(\Omega^g K(f)\) are homotopy equivalent.

C) Malcev’s theory

In order to construct our relative Chern character \(\text{ch}: \tilde{K} \wedge Q \rightarrow \tilde{HC}^Q_1[1]\), it is now enough to relate the homology of the relative Volodin spaces \(X(A,I)\) with cyclic homology. This step uses Malcev’s theory, that relates homology of nilpotent uniquely divisible groups (such as \(T^n_\sigma(A,I)\) for \(A\) discrete) with the homology of an associated nilpotent Lie algebra. The original reference is [Mal].

For simplicity, we will only work with Lie algebras of matrices. We assume for now that \(A\) is a discrete unital \(Q\)-algebra. Let \(n \subset \text{gl}_n(A)\) be a nilpotent sub-Lie algebra (for some \(n\)). Denote by \(N\) the subgroup \(N := \text{exp}(n) \subset \text{GL}_n(A)\). We have the following proposition (for a proof, we refer to [SW, Theorem 5.11]).

**Proposition 1.3.7** (Malcev, Suslin-Wodzicki). *There is a functorial quasi-isomorphism*

\[
\mathbb{Q}[BN] := C_\bullet(BN,Q) \rightarrow CE^Q_\bullet(n)
\]

*where \(BN\) denotes the classifying space of \(N\). Moreover, this quasi-isomorphism is compatible with the standard filtrations on those complexes.*

The construction of this quasi-isomorphism is based on two statements. First, the completion of the algebras \(U(n)\) and \(\mathbb{Q}[N]\) along their augmentation ideals are isomorphic and, second, the standard resolutions of \(\mathbb{Q}\) as a trivial module on those algebras are compatible. It follows that this quasi-isomorphism is actually compatible with the standard filtrations on both sides.
Fix $I \subset A$ a nilpotent ideal. For $n \in \mathbb{N}$ and $\sigma$ a partial order on $\{1, \ldots, n\}$, we denote by $t^*_n(A, I) \subset \mathfrak{gl}_n(A)$ the nilpotent Lie algebra of matrices $(a_{ij})$ such that $a_{ij} \in I$ if $i$ is not smaller than $j$ for the partial order $\sigma$. We have then by definition $T^*_n(A, I) = \exp(t^*_n(A, I))$ and therefore a quasi-isomorphism $\tau: \mathbb{Q}[BT^*_n(A, I)] \to CE^Q_\cdot(t^*_n(A, I))$ functorial in $A$ and $I$. Return now to the general case where $f: A \to B$ is a levelwise surjective morphism between unital simplicial $\mathbb{Q}$-algebras and $I$ is its kernel. Both functors $\mathbb{Q}[BT^*_n(-, -)]$ and $CE^Q_\cdot(t^*_n(-, -))$ preserve geometric realizations and we therefore get a (functorial) quasi-isomorphism
\[
\tau: \mathbb{Q}[BT^*_n(A, I)] \to CE^Q_\cdot(t^*_n(A, I))
\]
by applying $\tau$ levelwise.

**D) The relative Chern character** Using the natural inclusion $t^*_n(A, I) \to \mathfrak{gl}_n(A)$ and the generalized trace map, we get a morphism
\[
CE^Q_\cdot(t^*_n(A, I)) \to CE^Q_\cdot(\mathfrak{gl}_n(A)) \to \mathbb{H}C^Q_\cdot(f)[1]
\]
whose image lies in the subcomplex $\mathbb{H}C^Q_\cdot(f)[1]$. We find
\[
\mathbb{Q}[BT^*_n(A, I)] \xrightarrow{\sim} CE^Q_\cdot(t^*_n(A, I)) \xrightarrow{\tau} \mathbb{H}C^Q_\cdot(f)[1].
\]
Taking the colimit on $n$ and $\sigma$, we find a morphism
\[
\overline{\text{ch}}^Q: \mathbb{Q}[X(A, I)] \to \mathbb{H}C^Q_\cdot(f)[1].
\]

**Definition 1.3.8.** The relative Chern character is the (functorial) $\mathbb{Q}$-linear morphism
\[
\text{ch}: \mathbb{K}(f) \wedge \mathbb{Q} \to \mathbb{Q}[\Omega^{\infty} \mathbb{K}(f)] \simeq \mathbb{Q}[X(A, I)] \to \mathbb{H}C^Q_\cdot(f)[1].
\]

**Theorem 1.3.9 (Goodwillie [Goo]).** The morphism $\overline{\text{ch}}$ is a quasi-isomorphism.

**Remark 1.3.10.** As already noted above, the relative Chern character we just defined is not the one Goodwillie uses in [Goo]. Indeed, our relative Chern character does not a priori comes from an absolute Chern character. However, the two Chern characters have been proven homotopic by Cortiñas and Weibel in [CW], at least when evaluated on discrete algebras. If $f: A \to B$ is a surjective morphism of simplicial algebras, we can reduce to the discrete case. Indeed, writing $f$ as a geometric realization of discrete functors $f_n: A_n \to B_n$ and setting $I_n = \ker(f_n)$, we find $\mathbb{Q}[X(A, I)] \simeq \colim [n] \mathbb{Q}[X(A_n, I_n)]$ as well as $\mathbb{H}C^Q_\cdot(f) \simeq \colim [n] \mathbb{H}C^Q_\cdot(f_n)$. The relative Chern characters evaluated on $I \subset A \to B$ are then (both) determined by their value on discrete algebras, and therefore coincide using Cortiñas and Weibel’s result.

## 2 Formal deformation problems

Infinitesimal deformations of algebraic objects can be encoded by a tangential structure on the moduli space classifying those objects. In [Pri] and [DAG-X], Pridham and Lurie established an equivalence between so-called formal moduli problems and differential graded Lie algebras. This section starts by recalling Pridham and Lurie’s works. We then establish some basic facts about abelian or linear formal moduli problems.

### 2.1 Formal moduli problems and dg-Lie algebras

**Definition 2.1.1.** Let $\text{dgArt}_k \subset \text{cdga}_{k}^{\leq 0}/k$ denote the full subcategory of augmented connective $k$-cdga’s spanned by Artinian\(^5\) ones. Let $\mathcal{C}$ be an $\infty$-category with finite limits.

We say that a functor $F: \text{dgArt}_k \to \mathcal{C}$ satisfies the Schlessinger condition (S) if

---

\(^5\)Recall that $A$ is called Artinian if its cohomology is finite dimensional over $k$, and if $H^0(A)$ is a local ring with residue field $k$.  

13
The object $F(k)$ is final in $C$.

For any map $A \to B \in \mathbf{dgArt}_k$ that is surjective on $H^0$, the induced morphism $F(k \times_B A) \to F(k) \times_{F(B)} F(A)$ is an equivalence.

**Definition 2.1.2.** A pre-FMP (pre-formal moduli problem) is a functor $\mathbf{dgArt}_k \to \mathbf{sSets}$. We denote by $\mathbf{PFMP}_k$ their category. A FMP (formal moduli problem) is a pre-FMP $F$ satisfying the Schlessinger condition (S). We denote by $\mathbf{FMP}_k$ the category of formal moduli problems, and by $i : \mathbf{FMP}_k \to \mathbf{PFMP}_k$ the inclusion functor.

The category $\mathbf{PFMP}_k$ is presentable, and the full subcategory $\mathbf{FMP}_k$ is strongly reflexive. In particular, the inclusion $i : \mathbf{FMP}_k \to \mathbf{PFMP}_k$ admits a left adjoint.

**Definition 2.1.3.** We denote by $L : \mathbf{PFMP}_k \to \mathbf{FMP}_k$ the left adjoint to the inclusion $i$. We call it the formalization functor.

**Definition 2.1.4.** A shifted dg-Lie algebra over $k$ is a complex $V$ together with a dg-Lie algebra structure on $V[-1]$. We denote by $\mathbf{dgLie}^{\Omega}_k$ the category of shifted dg-Lie algebras.

**Remark 2.1.5.** The notation $\Omega$ is here to remind us the shift in the Lie structure. Note that shifting a complex $V$ by $-1$ amounts to computing its (pointed) loop space $\Omega V \simeq V[-1]$.

**Theorem 2.1.6** (Pridham, Lurie). The shifted tangent complex $T F[-1]$ of a formal moduli problem admits a Lie structure. Moreover, the functor $F \mapsto TF$ induces an equivalence $\mathbf{FMP}_k \simeq \mathbf{dgLie}^{\Omega}_k$.

**Definition 2.1.7.** We denote by $\ell$ the composite functor $\ell := T \circ L : \mathbf{PFMP}_k \to \mathbf{dgLie}^{\Omega}_k$, and by $e : \mathbf{dgLie}^{\Omega}_k \to \mathbf{FMP}_k$ the inverse functor $T^{-1}$.

Let us recall briefly how the equivalence in Theorem 2.1.6 is constructed. Consider the Chevalley-Eilenberg cohomological functor $\text{CE}^{\bullet}_k : \mathbf{dgLie}^{\Omega}_k \to \mathbf{cdga}_k$.

It admits a left adjoint, denoted by $\mathcal{D}_k$, so that for any $L$ and $B$, we have

$$\text{Map}_{\mathbf{dgLie}_k}(L, \mathcal{D}_k(B)) \simeq \text{Map}_{\mathbf{cdga}_k}(B, \text{CE}^{\bullet}_k(L)).$$

The equivalence $e : \mathbf{dgLie}^{\Omega}_k \simeq \mathbf{FMP}_k$ is then given on $V \in \mathbf{dgLie}^{\Omega}_k$ by the formula

$$e(V)(B) := \text{Map}_{\mathbf{dgLie}_k}(\mathcal{D}_k(B), V[-1]).$$

Proving this construction indeed defines an equivalence is based on the following key lemma

**Lemma 2.1.8** (see [DAG-X, 2.3.5]). For any $B \in \mathbf{dgArt}_k$, the adjunction morphism $B \to \text{CE}^{\bullet}_k(\mathcal{D}_k(B))$ is an equivalence.

In what follows, we will need slightly more general versions of formal moduli problems, namely formal moduli problems with values in an $\infty$-category such as complexes of vectors spaces or connective spectra.

**Definition 2.1.9.** Let $C$ be an $\infty$-category with all finite limits. A $C$-valued pre-FMP is a functor $\mathbf{dgArt}_k \to C$. A $C$-valued formal moduli problem (or FMP) is a $C$-valued pre-FMP satisfying the Schlessinger condition (S).

We denote by $\mathbf{PFMP}^C_k$ the category of $C$-valued pre-FMPs, by $\mathbf{FMP}^C_k$ the category of $C$-valued FMPs. We also denote by $i^C : \mathbf{FMP}^C_k \to \mathbf{PFMP}^C_k$ the inclusion functor.
**Lemma 2.1.10.** If $\mathcal{C}$ is a presentable $\infty$-category, then $\text{PFMP}_k^\mathcal{C}$ and $\text{FMP}_k^\mathcal{C}$ are presentable categories, and $i_\mathcal{C}$ admits a left adjoint.

**Definition 2.1.11.** In the above situation, we will denote by $L^\mathcal{C}$ the left adjoint to $i_\mathcal{C}$.

**Proof** (of Lemma 2.1.10). The presentability of $\text{PFMP}_k^\mathcal{C}$ is [HTT, 5.5.3.6]. Remains to prove that $\text{FMP}_k^\mathcal{C}$ is a strongly reflexive category (see [HTT, p.482]). Fix a cartesian square $(\sigma)$ in $\text{dgArt}_k$

\[
\begin{array}{ccc}
C & \longrightarrow & A \\
\downarrow & & \downarrow f \\
k & \longrightarrow & B
\end{array}
\]

where $f$ is surjective on $H^0$. We denote by $D_{\langle \sigma \rangle} \subset \text{PFMP}_k^\mathcal{C}$ the full subcategory spanned by functors $F$ mapping $(\sigma)$ to a pullback square. Since $\text{FMP}_k^\mathcal{C} = \bigcap_{\langle \sigma \rangle} D_{\langle \sigma \rangle}$ and because of [HTT, 5.5.4.18], it suffices to prove that $D_{\langle \sigma \rangle}$ is strongly reflexive in $\text{PFMP}_k^\mathcal{C}$.

Restriction along $\langle \sigma \rangle$ defines a functor $\sigma^*: \text{PFMP}_k^\mathcal{C} \to \text{Fct}(K, \mathcal{C})$ where $K = \Delta^1 \times \Delta^1$ is the square. The functor $\sigma^*$ admits a left adjoint $\sigma$ (namely the left Kan extension functor, see [HTT, 4.3.3.7]). A functor $F$ belongs to $D_{\langle \sigma \rangle}$ if and only if $\sigma^*(F)$ is a pullback square. By [HTT, 5.5.4.19], the full subcategory $\text{Fct}(K, \mathcal{C})$ spanned by pullback squares is strongly reflexive. It thus follows from [HTT, 5.5.4.17] that $D_{\langle \sigma \rangle}$ is strongly reflexive in $\text{PFMP}_k^\mathcal{C}$. \qed

We conclude this section by recording a functoriality statement, whose proof is straightforward and left to the reader.

**Lemma 2.1.12.** Let $f : \mathcal{C} \xrightarrow{\simeq} \mathcal{D} : g$ be an adjunction between presentable $\infty$-categories.

(i) Composing with $g$ induces a functor $g_* : \text{PFMP}_k^\mathcal{C} \to \text{PFMP}_k^\mathcal{D}$ that maps formal moduli problems to formal moduli problems.

(ii) The induced functor $g_* : \text{FMP}_k^\mathcal{D} \to \text{FMP}_k^\mathcal{C}$ admits a left adjoint $f_!$ given by the composition $f_! = L^\mathcal{D} \circ f_* \circ i_\mathcal{C}$, where $f_* : \text{PFMP}_k^\mathcal{C} \to \text{PFMP}_k^\mathcal{D}$ is the functor given by composing with $f$.

(iii) We have $f_! \circ L^\mathcal{C} \simeq L^\mathcal{D} \circ f_*$.  

### 2.2 Abelian moduli problems

The moduli problem of concern in this article is constructed from the (connective) $K$-theory functor. In particular, its values are endowed with an abelian group structure, or equivalently are connective spectra. We shall therefore establish a couple of basic properties of those abelian formal moduli problems.

#### A) Abelian formal moduli problems

Let us denote by $\text{FMP}_k^{\text{Ab}}$ (resp. $\text{PFMP}_k^{\text{Ab}}$) the category of abelian group objects (ie grouplike $E_\infty$-monoids) in (pre-)formal moduli problems. We call their objects abelian (pre-)formal moduli problems.

Forgetting the abelian group structure and the free abelian group functor form an adjunction

$$\Gamma^{\text{Ab}} : \text{FMP}_k \rightleftarrows \text{FMP}_k^{\text{Ab}} : G_{\text{Ab}}.$$  

We also have a similar adjunction

$$\Sigma_{\mathcal{C}} : \text{PFMP}_k \rightleftarrows \text{PFMP}_k^{\text{Ab}} : \Omega^\mathcal{C}.$$  

Note that the categories $\text{PFMP}_k^{\text{Ab}}$ and $\text{FMP}_k^{\text{Ab}}$ identify with $\text{PFMP}_k^\mathcal{C}$ (resp. $\text{FMP}_k^\mathcal{C}$) for $\mathcal{C} = \text{Sp}_{\geq 0}$ the category of connective spectra (see [HA, Rmk. 5.2.6.26]). In particular, the above adjunction is given by applying pointwise the functors $\Sigma_{\mathcal{C}} : \text{sSets} \rightleftarrows \text{Sp}_{\geq 0} : \Omega^\mathcal{C}$. Finally, we denote by $i_{\text{Ab}} : \text{FMP}_k^{\text{Ab}} \to \text{PFMP}_k^{\text{Ab}}$ the inclusion functor, and by $L^{\text{Ab}}$ its left adjoint.
\textbf{Remark 2.2.1.} We have a Beck-Chevalley natural transformation \( L \circ \Omega^X \to G_{AB} \circ I^{Ab} \). It is in general not an equivalence. In particular, an abelian pre-FMPs, such as the K-theory functor, will have two different associated formal moduli problems, and two different tangent Lie algebras (one of which will automatically be abelian, see below).

\textbf{B) Abelian dg-Lie algebras} It follows from Theorem 2.1.6 that the category \( \text{FMP}^{Ab}_k \) is equivalent to the category \( \text{dgLie}^{\Omega,Ab}_k \) of abelian group objects in \( \text{dgLie}^\Omega_k \). We shall call objects of \( \text{dgLie}^{\Omega,Ab}_k \) abelian dgLie algebras.

Although the following statement is well known to the community, we could not locate a proof in the literature. We therefore provide one.

\textbf{Proposition 2.2.2. The forgetful functor}

\[ \text{dgLie}^{\Omega,Ab}_k \to \text{dgMod}_k \]

is an equivalence. In particular \( \text{FMP}^{Ab}_k \cong \text{dgLie}^{\Omega,Ab}_k \cong \text{dgMod}_k \).

\textbf{Definition 2.2.3.} We denote by \( T^{Ab} : \text{FMP}^{Ab}_k \to \text{dgMod}_k \) the equivalence of the above proposition. We denote by \( e_{Ab} : \text{dgMod}_k \to \text{FMP}^{Ab}_k \) its inverse.

\textbf{Proof} (of the proposition). For any pointed category, we denote by \( \Omega \) its pointed loop space endofunctor. Denote by \( \text{FMP}^{P\times n}_k \) the category of FMP in \((n - 1)\)-connective spaces. In particular, we have \( \text{FMP}^{P\times n}_k = \text{FMP}_k \). The inclusion of \((n - 1)\)-connective spaces into all spaces induces a fully faithful functor \( \text{FMP}^{P\times n}_k \to \text{PFMP}_k \). We denote by \( u_n \) the composite

\[ u_n : \text{FMP}^{P\times n}_k \to \text{PFMP}_k \xrightarrow{L} \text{FMP}_k. \]

\textbf{Lemma 2.2.4.} The functor \( u_n \) is an equivalence.

\textbf{Proof.} For any \( \infty \)-category \( C \) with finite products, denote by \( \text{Mon}_{E_n}^{op}(C) \) the \( \infty \)-category of group-like \( E_n \)-monoids in \( C \) (see [HA0, Def. 5.2.6.6]). By [HA0, Thm. 5.2.6.10], the \( n \)-th loop space defines a (pointwise) equivalence \( \Omega^n : \text{FMP}^{P\times n}_k \to \text{Mon}_{E_n}^{op}(\text{FMP}_k) \).

It follows from [BKP, Prop. 2.15] that taking the \( n \)-th loop space also defines an equivalence \( \text{FMP}_k \to \text{Mon}_{E_n}^{op}(\text{FMP}_k) \). The inverse first applies pointwise the \( n \)-fold delooping \( B^n \), and then applies \( L \) to the obtained functor. The composition

\[ \text{FMP}^{P\times n}_k \xrightarrow{\Omega^n} \text{Mon}_{E_n}^{op}(\text{FMP}_k) \xrightarrow{L \circ B^n} \text{FMP}_k \]

is then homotopic to \( u_n \), and is an equivalence. \( \square \)

We continue our proof of Proposition 2.2.2. The forgetful functor \( f : \text{dgLie}^\Omega_k \to \text{dgMod}_k \) commutes with limits (and thus with \( \Omega \)). We get a commutative diagram, where the leftmost column is obtained by taking the limit of the rows

\[
\begin{array}{ccccccccc}
C_1 := \lim_{\rightarrow \infty} \text{FMP}^{P\times n}_k & \xrightarrow{=} & \cdots & \xrightarrow{=} & \text{FMP}^{P\times 2}_k & \xrightarrow{=} & \text{FMP}^{P\times 1}_k & \xrightarrow{=} & \text{FMP}^{P\times 0}_k \\
\cong_{\infty} & \cdots & \cong_{u_2} & \cong_{u_1} & \cong_{u_0} & \cong & \cong & \cong & \cong \\
C_2 := \lim_{\rightarrow \infty} \text{FMP}_k & \xrightarrow{=} & \cdots & \xrightarrow{=} & \text{FMP}_k & \xrightarrow{=} & \text{FMP}_k & \xrightarrow{=} & \text{FMP}_k \\
\cong_{\infty} & \cdots & \cong_{T} & \cong_{T} & \cong & \cong & \cong & \cong & \cong \\
C_3 := \lim_{\rightarrow \infty} \text{dgLie}^\Omega_k & \xrightarrow{=} & \cdots & \xrightarrow{=} & \text{dgLie}^\Omega_k & \xrightarrow{=} & \text{dgLie}^\Omega_k & \xrightarrow{=} & \text{dgLie}^\Omega_k \\
\xrightarrow{f} & \cdots & \xrightarrow{f} & \cdots & \xrightarrow{f} & \cdots & \xrightarrow{f} & \cdots & \xrightarrow{f} \\
C_4 := \lim_{\rightarrow \infty} \text{dgMod}_k & \xrightarrow{=} & \cdots & \xrightarrow{=} & \text{dgMod}_k & \xrightarrow{=} & \text{dgMod}_k & \xrightarrow{=} & \text{dgMod}_k.
\end{array}
\]

Since the category \( \text{dgMod}_k \) is stable, the projection on the rightmost component is an equivalence \( C_4 \cong \text{dgMod}_k \). The category \( C_1 \) identifies with the category of formal moduli problems in the
limit category $\lim(\cdots \to sSets_{\geq 1} \to sSets_{\geq 0}) \cong \mathbf{Sp}_{\geq 0}$. By \cite[Rmk. 5.2.6.26]{HA}, $\mathcal{C}_1$ is equivalent to $\text{FMP}_k^{\text{Ab}}$, and therefore $\mathcal{C}_1 \cong \text{dgLie}_{k}^{\Omega, \text{Ab}}$. Moreover, the equivalence $\mathbb{T}_x$ is homotopic to the equivalence $\text{FMP}_k^{\text{Ab}} \cong \text{dgLie}_{k}^{\Omega, \text{Ab}}$ induced directly from $\mathbb{T}_x^\prime$. By construction, the functor $\text{FMP}_k^{\text{Ab}}$ identifies with the functors forgetting the abelian group structure, while the functor $f_x : \text{dgLie}_{k}^{\Omega, \text{Ab}} \cong \mathcal{C}_1 \cong \text{dgMod}_k$ is the forgetful functor.

Remains to prove that $f_x$ is an equivalence. Since $f$ is conservative, so is $f_x$. The functor $f_x$ is the limit of functors with left adjoints, and therefore it admits a left adjoint $g_x$. Denote by $g$ the left adjoint of $f$. Up to a shift, the functor $g$ identifies with the free Lie algebra functor:

$$g(V) \cong \text{FreeLie}(V[-1])[1].$$

For a fixed $V \in \text{dgMod}_k \cong \mathcal{C}_4$, the adjunction unit $V \to f_x \circ g_x(V)$ identifies with the canonical map

$$\phi_V : V \to \colim_n \Omega^n(g(V[n])).$$

The full subcategory of $\text{dgMod}_k$ spanned by $V$’s such that $\phi_V$ is an equivalence is stable under filtered colimits. We may thus assume $V$ to be perfect, concentrated in (cohomological) degrees lower than some integer $m$. Fix $i \in \mathbb{Z}$. For $n > m + i$, the cohomology group $H^i(\Omega^n(g(V[n])))$ is independent of $n$ and isomorphic to $H^i(V)$. In particular, the map $\phi_V$ is a quasi-isomorphism. \(\square\)

**Definition 2.2.5.** We denote by $\text{CE}_k^\Omega : \text{dgLie}_{k}^{\Omega, \text{Ab}} \to \text{dgMod}_k$ the functor mapping a shifted dg-Lie algebra $L$ to the Chevalley-Eilenberg complex of its shift $\text{CE}_k(L[-1])$.

We denote by $\text{CE}_k^\Omega : \text{dgLie}_{k}^{\Omega, \text{Ab}} \to \text{dgMod}_k$ the functor mapping a shifted dg-Lie algebra $L$ to the Chevalley-Eilenberg complex of its shift $\text{CE}_k(L[-1])$.

**Definition 2.2.6.** We denote by $\theta : \text{dgMod}_k \cong \text{dgLie}_{k}^{\Omega, \text{Ab}} \to \text{dgLie}_{k}^{\Omega}$ the functor forgetting the abelian group structure.

**Lemma 2.2.7.** The functor $\theta : \text{dgMod}_k \to \text{dgLie}_{k}^{\Omega}$ identifies with the functor mapping a complex to itself with the trivial bracket. As a consequence, $\text{CE}_k^\Omega$ is left adjoint to $\theta$.

**Proof.** Denote by $h(V)$ the (shifted) dg-Lie algebra with trivial bracket built on $V \in \text{dgMod}_k$. Since $g$ is given as a free (shifted) dg-Lie algebra, there is a canonical morphism $g(V) \to h(V)$ given by collapsing the free brackets. By construction, the functor $\theta$ is given by the formula

$$\theta(V) \cong \colim_n \Omega^{n-1}(g(V[n-1])) \in \text{dgLie}_{k}^{\Omega}.$$ 

In particular, we find a functorial morphism in $\text{dgLie}_{k}^{\Omega}$

$$\theta(V) \cong \colim_n \Omega^{n-1}(g(V[n-1])) \to \colim_n \Omega^{n-1}(h(V[n-1])) \cong h(V).$$

We have already seen in the proof of Proposition 2.2.2 that the image by $f$ of this morphism is an equivalence. The first result follows by conservativity of $f$.

For the second statement, we simply observe that $\text{CE}_k^\Omega$ is the left derived functor of the abelianization functor $L \mapsto L[1]$, which is left adjoint to $h$. \(\square\)

**C** Description of the equivalence $\text{FMP}_k^{\text{Ab}} \cong \text{dgMod}_k$. We will give a more explicit description of the equivalence of Proposition 2.2.2. The definition implies that $\mathbb{T}_x^\prime : \text{FMP}_k^{\text{Ab}} \cong \text{dgMod}_k$ simply computes the tangent complex (at the only $k$-point). Let us also describe its inverse $e_{\text{Ab}}$. 

17
Lemma 2.2.8. Let $B \in \mathrm{dgArt}_k$ and $X = \text{Map}(B, -) \in \text{FMP}_k$. We have
\[ TF^0(X) \simeq \text{Aug}(B)^\vee, \]
where $\text{Aug}$ computes the augmentation ideal of a given Artinian, and $(-)^\vee$ computes the $k$-linear dual.

Proof. Since $B$ is Artinian, we deduce from Lemma 2.1.8 that $B$ is canonically equivalent to the Chevalley-Eilenberg cohomology of it (shifted) tangent Lie algebra $TX$. It follows that the tangent Lie algebra of $F^0 X$ is the dg-module $CE_*^q(TX) \simeq \text{Aug}(B)^\vee$.

Proposition 2.2.9. The functor $e_A$ is equivalent to the functor mapping $V \in \text{dgMod}_k$ to the abelian formal moduli problem
\[ B \mapsto \left( \text{Aug}(B) \otimes_k V \right)^{\leq 0}, \]
where $\text{Aug}$ computes the augmentation ideal of a given Artinian cdga and $(-)^{\leq 0}$ truncates the given complex (and considers it as a connective spectrum through the Dold-Kan equivalence).

Proof. The equivalence $\text{dgLie}_k^Q \simeq \text{FMP}_k$ is constructed by identifying $\text{dgArt}_k$ with a full subcategory of $\text{dgLie}_k^Q$ of so-called good (shifted) dg-Lie algebras, that generates $\text{dgLie}_k^Q$ in a certain way. This identification is given by the Chevalley-Eilenberg functor $CE_*^q$. In particular, given $V \in \text{dgMod}_k$, and $B \in \text{dgArt}_k$, we have
\[ e_A(V)(B) \simeq \text{Map}_{\text{FMP}_k^A} \left( F^0(\text{Map}(B, -)), e_A(V) \right) \]
\[ \simeq \text{Map}_{\text{dgMod}_k} \left( \text{Aug}(B)^\vee, V \right) \simeq \left( \text{Aug}(B) \otimes_k V \right)^{\leq 0}. \]

D) Diagrammatic summary. It follows from Proposition 2.2.2 that an abelian formal moduli problem is determined by its tangent complex (without any additional structure).

We denote by $\ell^A$ the composite functor $\ell^A := T^A \circ L^A$. We get the commutative diagrams of right adjoints and of left adjoints
\[
\begin{array}{cccc}
\text{dgLie}_k^Q & \xrightarrow{T} & \text{FMP}_k^A & \xrightarrow{i} & \text{PFMP}_k^A \\
\downarrow \sigma & & \downarrow G_A & & \downarrow \Omega^c \\
\text{dgMod}_k & \xrightarrow{e_A} & \text{PFMP}_k^A & \xrightarrow{i_A} & \text{PFMP}_k^A
\end{array}
\]

2.3 $\mathbb{Q}$-linear moduli problems

A) Definitions

Definition 2.3.1. A $\mathbb{Q}$-linear (pre-)FMP is a (pre-)FMP with values in $C = \text{dgMod}_k^{\Sigma 0}$. We shorten the notations by setting
\[ \text{FMP}_k^Q := \text{FMP}_k^C, \quad \text{PFMP}_k^Q := \text{PFMP}_k^C, \quad i_Q := i_C \quad \text{and} \quad L^Q := L^C. \]

We denote by $j_Q$ the forgetful functor $\text{PFMP}_k^Q \rightarrow \text{PFMP}_k$ and by $e_Q$ the functor $\text{dgMod}_k \rightarrow \text{FMP}_k^Q$ given by the formula
\[ e_Q(V) : B \mapsto \left( \text{Aug}(B) \otimes_k V \right)^{\leq 0} \in \text{dgMod}_k^{\Sigma 0}. \]

Recall that $e_A$ denotes the inverse of the equivalence $T : \text{FMP}_k^A \rightarrow \text{dgMod}_k$.
Proposition 2.3.2. The following assertions hold.

(a) The functor \( j_Q : \text{PFMP}_k^Q \to \text{PFMP}^{Ab}_k \) preserves formal moduli problems and is fully faithful.

(b) The functor \( e_{Ab} \) factors as

\[
e_{Ab} \simeq j_Q \circ e_Q : \text{dgMod}_k \xrightarrow{e_Q} \text{FMP}_k^Q \xrightarrow{j_Q} \text{FMP}^{Ab}_k.
\]

(c) The functors \( e_Q : \text{dgMod}_k \to \text{FMP}_k^Q \) and \( j_Q : \text{FMP}_k^Q \to \text{FMP}^{Ab}_k \) are equivalences.

As a consequence, we have the following factorization of the adjunction \( L^{Ab} \dashv i_{Ab} : \)

\[
\text{dgMod}_k \simeq \text{FMP}^{Ab}_k \xrightarrow{L^{Ab}} \text{FMP}_k^Q \simeq \text{FMP}^{Ab}_k.
\]

Proof. The functor \( j_Q \) is given by composing with the limit preserving functor \( \text{dgMod}_k^{\leq 0} \to \text{Sp}_{p>0} \).

In particular, it preserves the Schlessinger condition (S). Recall that \( Q \) is idempotent in spectra: \( Q \wedge Q \simeq Q \). It follows that \( j_Q \) is fully faithful. This proves assertion (a).

Proposition 2.2.9 implies assertion (b). All is left is assertion (c), which follows from assertion (a) and assertion (b). \( \square \)

Definition 2.3.3. We denote by \( T^Q : \text{dgMod}_k \to \text{FMP}_k^Q \) the inverse of \( e_Q \). We denote by \( \ell^Q \) the composite \( T^Q \circ L^Q \).

Remark 2.3.4. Since \( k \) is both initial and final in \( \text{dgArt}_k \), any \( F \in \text{PFMP}_k^Q \) (resp. in \( \text{PFMP}^{Ab}_k \)) splits as \( F \simeq \bar{F} \oplus F(k) \), where \( \bar{F} \) is pointed (ie satisfies the Schlessinger condition (S1)) and \( F(k) \) is the constant functor. Since the inclusion \( i_Q \) (resp. \( i_{Ab} \)) factors through the category of pointed functors, its left adjoint \( L^Q \) (resp. \( L^{Ab} \)) can be decomposed into two functors. The first associates \( \bar{F} \) to \( F \), while the second forces Schlessinger condition (S2). In particular, we have

\[
L^Q(F) \simeq L^Q(\bar{F}) \quad \text{and} \quad \ell^Q(F) \simeq \ell^Q(\bar{F}) \quad \text{resp.} \quad L^{Ab}(F) \simeq L^{Ab}(\bar{F}) \quad \text{and} \quad \ell^{Ab}(F) \simeq \ell^{Ab}(\bar{F}).
\]

B) Generators In this paragraph, we will identify families of generators of the category \( \text{PFMP}_k^Q \).

Definition 2.3.5. For \( B \in \text{dgArt}_k \), we denote by \( S^Q(B) \in \text{PFMP}_k^Q \) (resp. \( S^Q(B) \)) the functor

\[
S^Q(B) := C_*\left( \text{Map}_{\text{dgArt}_k}(B, -), Q \right) \quad \text{(resp.} \quad S^Q(B) := \overline{C_*}\left( \text{Map}_{\text{dgArt}_k}(B, -), Q \right) \),
\]

where \( C_*(-, Q) \) (resp. \( \overline{C_*}(-, Q) \)) computes the (reduced) rational homology of a given simplicial set.

Lemma 2.3.6. The category \( \text{PFMP}_k^Q \) is generated under colimits by functors of the form \( S^Q(B) \).

The full subcategory of \( \text{PFMP}_k^Q \) spanned by pointed functors (ie satisfying the Schlessinger condition (S1)) is generated under colimits by functors of the form \( S^Q(B) \).

Proof. Note that \( \text{PFMP}_k^Q \) is equivalent to the \( \infty \)-category of \( Q \)-linear objects in \( \text{PFMP}^{Ab}_k \). As a category of presheaves, \( \text{PFMP}_k \) is generated under colimits by the representable functors \( \text{Map}_{\text{dgArt}_k}(B, -) \) (for \( B \in \text{dgArt}_k \)). It follows that \( \text{PFMP}_k^Q \) is generated under colimits by the free \( Q \)-linear presheaves generated by those \( \text{Map}_{\text{dgArt}_k}(B, -) \), ie by the \( S^Q(B) \)'s. The second statement follows. \( \square \)

We now compute explicitly the formal moduli problem associated to such a generator.
Lemma 2.3.7. Let $B \in \text{dgArt}_k$. There are functorial equivalences $\ell^Q(S^0(B)) \simeq \ell^Q(S^0(B)) \simeq \text{Aug}(B)^\vee$, where $(-)^\vee$ computes the $k$-linear dual and Aug the augmentation.

Proof. From Remark 2.3.4, we have $\ell^Q(S^0(B)) \simeq \ell^Q(S^0(B))$. The result then follows from Lemma 2.2.8 in conjunction with the factorization from Proposition 2.3.2. □

C) Monoidality We will now consider monoidal structures on the adjunction

$$\ell^Q: \text{PFMP}_k^Q \rightleftarrows \text{FMP}_k^Q \simeq \text{dgMod}_k: e_Q.$$  

We first observe that both sides admit a natural tensor structure: $\otimes_k$ on the RHS, and the pointwise application of $\otimes_Q$ on the LHS.

Lemma 2.3.8. The functor $e_Q$ is non-unitaly lax symmetric monoidal.

Proof. We consider the constant moduli problem functor $\text{dgMod}_k \rightarrow \text{PFMP}_k^Q$ mapping $V$ to the constant functor $V$. It is right adjoint to the symmetric monoidal functor $F \mapsto F(k) \otimes_k k$ and therefore inherits a lax monoidal structure.

Let $I$ be the functor $I: \text{dgArt}_k \rightarrow \text{dgMod}_k^Q$ mapping an Artinian $B$ to its augmentation ideal $\text{Aug}(B)$. It is by construction an ideal in the commutative algebra object $I: B \mapsto B$ and therefore inherits a non-unital commutative algebra structure.

In particular, the functor $e_Q: V \mapsto V \otimes_k I$ is non-unitaly lax symmetric monoidal. □

As a direct consequence of this lemma, we get that the functor $\ell^Q$ is non-unitaly colax symmetric monoidal.

Proposition 2.3.9. The functor $\ell^Q$ is non-unitaly symmetric monoidal once restricted to the full subcategory of pointed functors.

Proof. We are to prove that for any pair $F, G \in \text{PFMP}_k^Q$ of pointed functors (ie $F(k) \simeq G(k) \simeq 0$), the natural morphism

$$\gamma_{F,G}: \ell^Q(F \otimes G) \rightarrow \ell^Q(F) \otimes \ell^Q(G)$$

is an equivalence. Fixing $F$, we denote by $D_F \subset \text{PFMP}_k^Q$ the full subcategory spanned by the $G$'s such that $\gamma_{F,G}$ is an equivalence. Since the tensor products $\otimes_k$ and $\otimes_Q$ preserve colimits in each variable, and since $\ell^Q$ preserves colimits, the category $D_F$ is stable under colimits. Using Lemma 2.3.6, we can therefore reduce the question to the case where $G$ (and by symmetry, also $F$) is of the form $S^0(B)$. Let $B_1$ and $B_2$ be Artinian cdgas over $k$, and assume that $F = S^0(B_1)$ and $G = S^0(B_2)$.

The reduced Künneth formula provides a (functorial) equivalence

$$S^0(B_1 \otimes_k B_2) \simeq \mathcal{C}_* \left( \text{Map}_{\text{dgArt}_k}(B_1, -) \times \text{Map}_{\text{dgArt}_k}(B_2, -), \mathbb{Q} \right) \simeq S^0(B_1) \otimes^Q S^0(B_2) \oplus S^0(B_1) \otimes S^0(B_2).$$

Applying $\ell^Q$ on that equivalence, we find using Lemma 2.3.7

$$\text{Aug}(B_1 \otimes_k B_2)^\vee \simeq \ell^Q(S^0(B_1) \otimes^Q S^0(B_2)) \oplus \text{Aug}(B_1)^\vee \oplus \text{Aug}(B_2)^\vee.$$  

Since $B_1$ and $B_2$ are perfect as $k$-dg-modules, the LHS identifies with

$$\text{Aug}(B_1)^\vee \oplus \text{Aug}(B_2)^\vee \oplus \text{Aug}(B_1)^\vee \oplus \text{Aug}(B_2)^\vee.$$  

The map $\gamma_{S^0(B_1), S^0(B_2)}$ is thus a retract of the equivalence $\ell^Q(S^0(B_1 \otimes_k B_2)) \simeq \text{Aug}(B_1 \otimes_k B_2)^\vee$ and is therefore itself an equivalence. □
Lemma 2.3.10. Let $C \in \cdga_{\mathbb{Q}}$, let $V \in \dgMod_{\mathbb{Q}}$ and let $F: \dgArt_{\mathbb{k}} \to \dgMod_{\mathbb{Q}}$ be a pre-FMP. Tensoring pointwise by $V$ defines a new pre-FMP $F \otimes_{\mathbb{C}} V$. The canonical morphism

$$
\ell^Q \left( F \otimes_{\mathbb{C}} V \right) \to (\ell^Q F) \otimes_{\mathbb{C}} V
$$

is an equivalence in $\dgMod_{\mathbb{k}}$.

Proof. Since the involved functors preserves all colimits, we can reduce to the generating case $V = C$, which is trivial.

Corollary 2.3.11. Let $F, G \in \PFMP_{\mathbb{Q}}$. If $F$ is pointed (ie $F(\mathbb{k}) \simeq 0$) and if $\ell^Q (F) \simeq 0$, then $\ell^Q (F \otimes_{\mathbb{Q}} G) \simeq 0$.

Proof. We split $G$ into the direct sum $\tilde{G} \oplus G(\mathbb{k})$ where $\tilde{G}$ is pointed and $G(\mathbb{k})$ is a constant functor. We can therefore assume that $G$ is either pointed or constant. The first case follows from Proposition 2.3.9, while the second case follows from Lemma 2.3.10 (for $C = \mathbb{Q}$).

3 Excision

In this section, we fix $\mathcal{A}$ an algebra object in $\PFMP_{\mathbb{Q}}$. We also denote by $\tilde{\mathcal{A}}$ the associated pointed functor

$$
\tilde{\mathcal{A}}: B \mapsto \text{hofib}(\mathcal{A}(B) \to \mathcal{A}(\mathbb{k})).
$$

Note that $\tilde{\mathcal{A}}$ inherits a non-unital algebra structure. Finally, we denote by $A$ the (non-unital) algebra $\ell^Q (\mathcal{A}) \simeq \ell^Q (\tilde{\mathcal{A}})$ in $\DGMod_{\mathbb{k}}$.

3.1 Main theorem

Theorem 3.1.1. Consider the canonical morphisms

$$
\begin{align*}
\HH^Q_*(\tilde{\mathcal{A}}) &\xrightarrow{\alpha_{\text{HH}}} \HH^Q_*(A) \\
\HC^Q_*(\tilde{\mathcal{A}}) &\xrightarrow{\alpha_{\text{HC}}} \HC^Q_*(A)
\end{align*}
$$

The following holds:

(a) The morphisms $\beta_{\text{HH}} \circ \ell^Q (\alpha_{\text{HH}})$ and $\beta_{\text{HC}} \circ \ell^Q (\alpha_{\text{HC}})$ are equivalences.

(b) If $\mathcal{A}$ is $H$-unital, then the morphisms $\ell^Q (\alpha_{\text{HH}})$ and $\ell^Q (\alpha_{\text{HC}})$ are equivalences (and therefore so are $\beta_{\text{HH}}$ and $\beta_{\text{HC}}$).

Remark 3.1.2. A direct consequence of assertion (b) is that the tangent to Hochschild or cyclic homology of a given functor $\mathcal{A}$ does not depend on $\mathcal{A}(\mathbb{k})$. This is an excision statement similar to Theorem 1.2.2.

Corollary 3.1.3. Let $C \in \dgAlg_{\mathbb{k}}^{un}$ be $H$-unital. Denote by $\mathcal{A}_C$ the functor $B \mapsto (C \otimes_{\mathbb{k}} B)^{e0}$. There is a functorial equivalence

$$
\ell^{Ab}(K(\mathcal{A}_C)) \simeq \HC^k_*(C)[1].
$$

Proof. We have $\tilde{\mathcal{A}}_C = e^Q_0(C)$ and therefore $\ell^Q (\mathcal{A}_C) \simeq \ell^Q (\tilde{\mathcal{A}}_C) \simeq C$. We find

$$
\ell^{Ab}(K(\mathcal{A}_C)) \simeq \ell^{Ab}(\tilde{K}(\mathcal{A}_C))
$$

by Remark 2.3.4

$$
\simeq \ell^Q (\tilde{K}(\mathcal{A}_C) \wedge Q)
$$

by Proposition 2.3.2

$$
\simeq \ell^Q (\HC^Q_*(\mathcal{A}_C))[1]
$$

by Theorem 1.3.9

$$
\simeq \ell^Q (\HC^Q_*(\mathcal{A}_C))[1]
$$

by Remark 2.3.4

$$
\simeq \HC^k_*(C)[1]
$$

by Theorem 3.1.1.
Remark 3.1.4. The equivalence of Corollary 3.1.3 is defined through the relative Chern character. We know from [Cat] and [CHW] that the Chern character is compatible with the \( \lambda \)-operations on both sides. It follows that the equivalence of Corollary 3.1.3 is also compatible with the \( \lambda \)-operations.

Lemma 3.1.5. Let \( M \in \mathbf{PFMP}^Q_k \) be an \( \mathcal{A} \)-bimodule. Assume that \( M(k) \approx 0 \). We set \( M := \ell^Q(M) \) as an \( \mathcal{A} \)-bimodule. The canonical morphisms

\[
\beta \alpha_B : \ell^Q(B^Q_*(\mathcal{A}, M)) \to B^k_*(\mathcal{A}, M)
\]

\[
\beta \alpha_H : \ell^Q(H^Q_*(\mathcal{A}, M)) \to H^k_*(\mathcal{A}, M)
\]

are equivalences.

Proof. The augmented Bar complex \( B^Q_*(\mathcal{A}, M) \) identifies as the homotopy cofiber of the augmentation \( B_Q(\mathcal{A}, M) \to M \), where \( B_Q(-, -) \) denotes the reduced Bar complex. The latter is obtained as a homotopy colimit of the semi-simplicial Bar construction. Since \( \ell^Q \) preserves colimits, we find using Proposition 2.3.9

\[
\ell^Q(B_Q(\mathcal{A}, M)) \approx \ell^Q\left(\lim_{\Delta} M \otimes A^\otimes n_{\Delta} \right) \approx \lim_{\Delta} M \otimes A^\otimes n_{\Delta} \approx B_k(\mathcal{A}, M).
\]

Taking the homotopy cofiber of the augmentation on both sides, we find the first claimed equivalence. Similarly, the functor \( H^Q_*(\mathcal{A}, M) \) is again the homotopy colimit of a standard semi-simplicial diagram. \( \square \)

Proof (of Theorem 3.1.1 (a)). The functor \( HH^Q_* \) is the homotopy cofiber of the natural transformation \( 1 - t : B^Q_n \to H^Q_\bullet \). In particular, the morphism \( \beta_H \circ \ell^Q(\alpha_H) \) is an equivalence because of Lemma 3.1.5 (for \( M = \mathcal{A} \)) and the fact that \( \ell^Q \) preserves cofiber sequences. In the case of \( HC \), we use Remark 1.1.8 and Lemma 2.3.10:

\[
\ell^Q\left(HC^Q_*(\mathcal{A})\right) \approx \ell^Q\left(HH^Q_*(\mathcal{A}) \otimes Q_{[c]}\right) \approx \ell^Q\left(HH^Q_*(\mathcal{A}) \otimes Q_{[c]} \right) \approx HH^k_*(\mathcal{A}) \otimes Q_{[c]} \approx HC^k_*(\mathcal{A}),
\]

where \( Q_{[c]} := H_*(S^1, Q) \in \mathbf{cdga}_Q^{\otimes 0} \). \( \square \)

3.2 Proof of assertion (b)

The proof of assertion (b) in Theorem 3.1.1 is more evolved and relies on the ideas behind Wodzicki’s Theorem 1.2.2. We first reduce the study of Hochschild and cyclic homology to that of the complexes \( H \) and \( B \) from subsection 1.1. We will use the following terminology:

Definition 3.2.1. A morphism \( f : F \to G \in \mathbf{PFMP}^Q_k \) is an \( \ell^Q \)-equivalence if \( \ell^Q(f) \) is an equivalence.

Denote by \( \alpha_H \) and \( \alpha_B \) the canonical morphisms

\[
\begin{align*}
H^Q_*(\mathcal{A}) & \xrightarrow{\alpha_H} H^Q_*(\mathcal{A}), \\
B^Q_*(\mathcal{A}) & \xrightarrow{\alpha_B} B^Q_*(\mathcal{A}).
\end{align*}
\]

As in the previous section, we can easily reduce the proof of Theorem 3.1.1, assertion (b) to proving that both \( \alpha_H \) and \( \beta_H \) are \( \ell^Q \)-equivalences.

Lemma 3.2.2. If both \( \alpha_H \) and \( \alpha_B \) are \( \ell^Q \)-equivalences, then so are \( \alpha_{HH} \) and \( \alpha_{HC} \).
We will now focus on $\alpha_H$ and $\alpha_B$ using techniques from subsection 1.2.

**Proposition 3.2.3.** The canonical morphisms

$$\alpha_B: B^q_\alpha(\mathcal{A}) \to B^q(A) \quad \text{and} \quad \alpha_H: H^q_\alpha(\mathcal{A}) \to H^q(A)$$

are $\ell^q$-equivalences.

**Lemma 3.2.4.** Let $M \in \text{PFMP}^q_M$ be an $A$-bimodule. Assume that $\mathcal{M}(k) \simeq 0$ and that $M := \ell^q(M)$ is $H$-unital as an $A = \ell^q(\mathcal{A})$-bimodule, then

$$\gamma_H: H^q_\alpha(\mathcal{A}, M) \to H^q_\alpha(A, M) \quad \text{and} \quad \gamma_B: B^q_\alpha(\mathcal{A}, M) \to B^q(A, M)$$

are $\ell^q$-equivalences.

**Proof.** We focus on $\gamma_H$, the case of $\gamma_B$ being identical. Denote by $f$ the canonical natural transformation $\mathcal{A} \to \mathcal{A}(k)$ (where on the RHS is the constant functor). We get $\mathcal{A} \simeq \text{hofib}(f)$. Recall from subsection 1.2 paragraph A) the filtration

$$H^q_\alpha(\mathcal{A}, M) \simeq F^q_{H^q_\alpha}(f, M) \to \cdots \to F^q_{H^q_\alpha}(f, M) \to \cdots \to \colim_n F^q_{H^q_\alpha}(f, M) \simeq H^q_\alpha(\mathcal{A}, M).$$

Applying $\ell^q$, we find

$$\ell^q(H^q_\alpha(\mathcal{A}, M)) \simeq \ell^q(F^q_{H^q_\alpha}(f, M)) \to \cdots \to \ell^q(F^q_{H^q_\alpha}(f, M)) \to \cdots \to \colim_n \ell^q(F^q_{H^q_\alpha}(f, M)).$$

Since $\ell^q$ is a left adjoint and thus preserves colimits, we have

$$\colim_n \ell^q(F^q_{H^q_\alpha}(f, M)) \simeq \ell^q(\colim_n F^q_{H^q_\alpha}(f, M)) \simeq \ell^q(H^q_\alpha(\mathcal{A}, M)).$$

It therefore suffices to prove that for any $n \geq 0$, the morphism $F^q_{H^q_\alpha}(f, M) \to F^{q+1}_{H^q_\alpha}(f, M)$ is an $\ell^q$-equivalence. Denote by $F^n$ the complex $\ell^q(F^q_{H^q_\alpha}(f, M))$. Since $\text{dgMod}_k$, the codomain of $\ell^q$, is a stable $\infty$-category, it is enough to check that

$$F^{n+1}/F^n \simeq \ell^q(F^{n+1}_{H^q_\alpha}(f, M)/F^n_{H^q_\alpha}(f, M))$$

is contractible. Using Lemma 1.2.3, we get

$$F^{n+1}_{H^q_\alpha}(f, M)/F^n_{H^q_\alpha}(f, M) \simeq \mathcal{A}^\otimes \otimes \mathcal{A}(k) \otimes B^q_\alpha(\mathcal{A}, M)[n + 1].$$

From Lemma 3.1.5, we have $\ell^q(B^q_\alpha(\mathcal{A}, M)) \simeq B^q(\mathcal{A}, M) \simeq 0$ (using the assumption that $M$ is $H$-unital over $A$). Since the functor $B^q_\alpha(\mathcal{A}, M)$ is pointed, we get that $F^{n+1}/F^n \simeq 0$ using Corollary 2.3.11. We conclude that $\gamma_H$ is an $\ell^q$-equivalence. \hfill $\square$

**Lemma 3.2.5.** If $A$ is $H$-unital, the four canonical morphisms

$$H^q_\alpha(A, A(k)) \xrightarrow{\Delta A} H^q_\alpha(A(k), A(k)) \to 0$$

$$B^q_\alpha(A, A(k)) \xrightarrow{\Delta A} B^q_\alpha(A(k), A(k)) \to 0$$

are $\ell^q$-equivalences.
Proof. The functors $\mathcal{H}_G^k(\mathcal{A}(k), \mathcal{A}(k))$ and $\mathcal{B}_G^k(\mathcal{A}(k), \mathcal{A}(k))$ are constant. Their image by $\ell^G$ thus vanish, by Remark 2.3.4. It follows that their projections to 0 are $\ell^G$-equivalences. We now focus on the maps $\delta_H$ and $\delta_S$. Let $f: \mathcal{A} \to \mathcal{A}(k)$ be the augmentation. Recall from subsection 1.2 on paragraph B) the filtrations by quotients:

\[
\mathcal{B}_G^k(\mathcal{A}(k), \mathcal{A}(k)) \cong \mathcal{H}_G^k(\mathcal{A}(k), \mathcal{A}(k)) \cong \mathcal{B}_G^k(\mathcal{A}(k), \mathcal{A}(k)).
\]

Since $\ell^G$ preserves colimits, it suffices to prove that the transition morphisms $Q^n \to Q^{n+1}$ are $\ell^G$-equivalences. Denote by $\mathcal{M}(n)$ the $\mathcal{A}$-bimodule $\mathcal{A}(k)^{\otimes n+1} \otimes \mathcal{A}$ and by $\mathcal{M}(n)$ its image by $\ell^G$. We get from Lemma 1.2.6 two fiber and cofiber sequences

\[
\mathcal{B}_G^k(\mathcal{A}, \mathcal{M}(n))[n+1] \longrightarrow Q^n_{B_G}(f) \longrightarrow Q^{n+1}_{B_G}(f) \longrightarrow \colim_n Q^n_{B_G}(f) \cong \mathcal{H}_G^k(\mathcal{A}(k), \mathcal{A}(k)).
\]

Their image by $\ell^G$ are still cofiber sequences, and it is now enough to prove that both $\mathcal{B}_G^k(\mathcal{A}, \mathcal{M}(n))$ and $\mathcal{H}_G^k(\mathcal{A}, \mathcal{M}(n))$ are cancelled by $\ell^G$. We first observe that $\mathcal{M}(n)$ is pointed: $\mathcal{M}(n)(k) \simeq 0$. Moreover, we have by Lemma 2.3.10

\[
\mathcal{M}(n) = \ell^G(\mathcal{M}(n)) \cong \mathcal{A}(k)^{\otimes n+1} \otimes \mathcal{Q}(\mathcal{A}) = \mathcal{A}(k)^{\otimes n+1} \otimes \mathcal{A}.
\]

Remark 1.1.4 implies that $\mathcal{M}(n)$ is coacyclic over $\mathcal{A}$. Using Lemma 3.2.4, we are reduced to the study of $\mathcal{B}_G^k(\mathcal{A}, \mathcal{M}(n))$ and $\mathcal{H}_G^k(\mathcal{A}, \mathcal{M}(n))$. By Lemma 3.1.5, we get

\[
\ell^G(\mathcal{B}_G^k(\mathcal{A}, \mathcal{M}(n))) \cong \mathcal{B}_G^k(\mathcal{A}, \mathcal{M}(n)) \cong 0
\]

and, since the left action of $A$ on $\mathcal{M}(n)$ is trivial:

\[
\ell^G(\mathcal{H}_G^k(\mathcal{A}, \mathcal{M}(n))) \cong \mathcal{H}_G^k(\mathcal{A}, \mathcal{M}(n)) \cong \mathcal{B}_G^k(\mathcal{A}, \mathcal{M}(n)) \cong 0.
\]

\[\square\]

Proof (of Proposition 3.2.3). We first observe that $\alpha_B$ and $\alpha_H$ factor as

\[
\mathcal{B}_G^k(\mathcal{A}) \xrightarrow{\gamma_B} \mathcal{B}_G^k(\mathcal{A}, \mathcal{A}) \xrightarrow{\eta_B} \mathcal{B}_G^k(\mathcal{A})
\]

\[
\mathcal{H}_G^k(\mathcal{A}) \xrightarrow{\gamma_H} \mathcal{H}_G^k(\mathcal{A}, \mathcal{A}) \xrightarrow{\eta_H} \mathcal{H}_G^k(\mathcal{A}).
\]

Since $A$ is H-unital and $\mathcal{A}$ is pointed, Lemma 3.2.4 implies that $\gamma_B$ and $\gamma_H$ are $\ell^G$-equivalences. The homotopy cofibers of $\eta_B$ and $\eta_H$ are respectively $\mathcal{B}_G^k(\mathcal{A}, \mathcal{A}(k))$ and $\mathcal{H}_G^k(\mathcal{A}, \mathcal{A}(k))$. They are cancelled by $\ell^G$ because of Lemma 3.2.5. It follows that $\eta_B$ and $\eta_H$ are $\ell^G$ equivalences, and so are $\alpha_B$ and $\alpha_H$.

This concludes the proof of Proposition 3.2.3 and therefore the proof of Theorem 3.1.1. \[\square\]

4 Application: the generalized trace map

Let $A$ be a connective dg-algebra. Recall from subsection 1.1, paragraph B), that the generalized trace map is a (functorial) morphism

\[
\text{Tr}: \text{CE}_X^k(\text{gl}_X(A)) \to \text{HC}_X^k(A)[1].
\]

A morphism $\text{CE}_X^k(\text{gl}_X(A)) \to \text{HC}_X^k(A)[1]$ such as $\text{Tr}$ amounts to an $\mathcal{L}_X$-morphism $\text{gl}_X(A) \to \text{HC}_X^k(A)$, where the RHS is considered with its abelian $\mathcal{L}_X$-structure. It corresponds to a map $\text{Tr}: \text{gl}_X(A) \to \text{HC}_X^k(A)$ in the $\infty$-category $\text{dgLie}_k$, or equivalently to a map

\[
\text{gl}_X(A)[1] \to \mathcal{H}(\text{HC}_X^k(A)[1])
\]

24
in the $\infty$-category $\text{dgLie}_{k}^{\Omega}$ of shifted dg-Lie algebras. Recall that $\theta: \text{dgMod}_{k} \to \text{dgLie}_{k}^{\Omega}$ maps a $k$-dg-module to the abelian shifted dg-Lie algebra built on that module.

In this section, we will prove that the generalized trace $\text{Tr}$ is tangent (in the sense of formal moduli problems) to the canonical morphism of functors $BGL \to K$ mapping a vector bundle to its class in $K$-theory. We will see that $BGL \to K$ induces a tangent morphism $T: \text{gl}_{n}(A) \to \theta(\text{HC}_{k}^{\ast}(A))$ of dg-Lie algebras over $k$ and that $T$ is homotopic to the generalized trace $\text{Tr}_n$. See Theorem 4.2.1 below for a precise statement.

4.1 The tangent of $BGL$

Let $A_{A}: \text{dgArt}_{k} \to \text{dgAlg}_{k}^{\leq 0}$ denote the functor $B \mapsto A \otimes_{k} B$. Denote by $\overline{A}_{A}$ its augmentation ideal $\overline{A}(B) := A \otimes_{k} \text{Aug}(B)$.

**Definition 4.1.1.** Let $n \in \mathbb{N}$ and let $A: \text{dgArt}_{k} \to \text{dgAlg}_{k}^{\leq 0}$ be any functor. We denote by $BGL_{n}(A)$ the functor $\text{dgArt}_{k} \to \text{sSets}$ mapping $B \in \text{dgArt}_{k}$ to

$$BGL_{n}(A)(B) := \text{hofib}(BGL_{n}(A(B)) \to BGL_{n}(A(k))).$$

**Remark 4.1.2.** The canonical morphism $\text{colim}_{n \in \mathbb{N}} BGL_{n}(A) \to BGL_{\infty}(A)$ is an equivalence.

**Remark 4.1.3.** We assume $A = A_{A}$. Denote by $\text{exp}(\text{gl}_{n}(\overline{A}_{A}))(B)$ the (nilpotent) subgroup of $\text{GL}_{n}(A_{A}(B))$ of matrices of the form $1 + M$, where $M$ is a matrix with coefficients in $\overline{A}_{A}(B) \approx A \otimes_{k} \text{Aug}(B)$. We can then identify the homotopy fiber $BGL_{n}(A_{A})$ with

$$BGL_{n}(A_{A}) \approx \text{GL}_{n}(A_{A}(k))/\text{GL}_{n}(A_{A}) = B \text{exp}(\text{gl}_{n}(\overline{A}_{A})).$$

For later use, we will work in a slightly bigger generality. Let $R$ be a (possibly non-unital) discrete $k$-algebra. We denote by $\mathfrak{g}_{R}$ the functor

$$\mathfrak{g}_{R}: \text{dgAlg}_{k}^{\leq 0,\text{un}} \to \text{dgLie}_{k}^{\leq 0}$$

mapping a connective dg-algebra $C$ to the Lie algebra underlying the associative algebra $C \otimes_{k} R$. Examples include the case where $R$ is the algebra of $n \times n$-matrices with coefficients in $k$, where we find $\mathfrak{g}_{R} = \text{gl}_{n}$. Obviously, the construction $R \mapsto \mathfrak{g}_{R}$ is functorial.

For an algebra $R$, we also denote by $B\text{G}_{R}(A_{A}) \in \text{PFMP}_{k}$ the functor

$$B\text{G}_{R}(A_{A}): B \mapsto B \text{exp}(\mathfrak{g}_{R}(\overline{A}_{A}(B))) = B \text{exp}\left(\mathfrak{g}_{R}(A \otimes_{k} \text{Aug}(B))\right).$$

**Lemma 4.1.4.** There is a functorial (in $R$) equivalence

$$\ell(B\text{G}_{R}(A_{A})) \simeq \mathfrak{g}_{R}(A)[1] \in \text{dgLie}_{k}^{\Omega}.$$ 

**Proof.** Denote by $R^{+}$ the unital $k$-algebra obtained by formally adding a unit to $R$. Consider the functor $F: \text{dgArt}_{k} \to \text{sSets}$ mapping $B$ to the maximal $\infty$-groupoid in

$$\text{Perf}_{R^{+} \otimes_{k} A \otimes_{k} B^{+}}.$$

Deformations of the perfect module $R \otimes_{k} A$ are then controlled by the functor $\text{Def}(R \otimes_{k} A): B \mapsto F(B) \otimes_{F(k)} (R \otimes A)$. It follows from [DAG-X, Cor. 5.2.15 and Thm. 3.3.1] that the deformations of $R \otimes_{k} A$ are controlled by the dg-Lie algebra $\mathfrak{g}_{R}(A) = \text{End}(R \otimes_{k} A)$. Moreover, we have a natural transformation $B\text{G}_{R}(A_{A}) \to \text{Def}(R \otimes_{k} A)$ which induces an equivalence on the loop groups. It is therefore an $\ell$-equivalence and the result follows.

**Corollary 4.1.5.** For any $n \in \mathbb{N} \cup \{\infty\}$, the (shifted) tangent Lie algebra of $BGL_{n}(A_{A})$ is $\text{gl}_{n}(A)[1]$. 

25
4.2 The generalized trace

Let \( A : \text{dgArt}_k \to \text{dgAlg}_\leq \) be any functor. It comes with a canonical natural transformation \( \text{BGL}_x(A) \to \Omega^2 K(A) \) mapping a vector bundle to its class. We can now state the main result of this section:

**Theorem 4.2.1.** Let \( A \) be a connective unital dg-algebra over \( k \), and let \( A^\bullet : \text{dgArt}_k \to \text{dgAlg}_\leq \) be the functor \( B \mapsto B \otimes_k A \). The natural transformation \( \text{BGL}_x(A) \to \Omega^2 K(A) \) induces, by taking the tangent, a morphism

\[
T : \mathfrak{gl}_x(A)[1] \to \ell(\text{BGL}_x(A)) \to \theta \ell^{Ab}(\text{K}(A)) \simeq \theta \ell^0(\text{HC}_k^\ast(A)[1])
\]

in \( \text{dgLie}_k \). The morphisms \( T \) and \( \ell \) are homotopic.

**Proof.** Recall that the equivalence \( \ell^{Ab}(\text{K}(A)) \simeq \text{HC}_k^\ast(A)[1] \) is built through the relative Chern character \( \text{K}(A) \to j_\ast \text{HC}_k^\ast(A)[1] \). In particular, the morphism \( T \) is induced by the natural transformation

\[
\text{ch}_{\text{GL}} : \text{BGL}_x(A) \to \Omega^2 K(A) \to \nu \text{HC}_k^\ast(A)[1]
\]

where \( \nu \simeq \Omega^2 \circ j_\ast : \text{PFMP}_k^\text{GL} \to \text{PFMP}_k^\text{GL} \) is the forgetful functor. Denote by \( \text{Q}[-] \) the left adjoint to \( \nu \) (so that it computes pointwise the rational homology of the given simplicial set). The natural transformation \( \text{ch}_{\text{GL}} \) then factors as

\[
\tilde{\text{ch}}_{\text{GL}} : \text{BGL}_x(A) \to \nu X(\text{A}, A) \to \nu \text{HC}_k^\ast(A)[1].
\]

Recalling the construction of \( \tilde{\text{ch}}^Q \) and using Malcev’s theory for \( \mathfrak{gl}_x(A) \), we get the commutative diagram

\[
\begin{array}{ccc}
\text{BGL}_x(A) & \to & \nu X(\text{A}, A) \\
\downarrow_{\approx} & & \downarrow_{\approx} \\
\nu \text{CE}^Q(\mathfrak{gl}_x(A)) & \to & \nu \text{HC}_k^\ast(A)[1] \\
\end{array}
\]

By functoriality of the generalized trace map, we find that the composite map \( \ell \circ \text{tr} \) is homotopic to

\[
\nu \text{CE}^Q(\mathfrak{gl}_x(A)) \to \text{HC}_k^\ast(A)[1] \to \text{HC}_k^\ast(A)[1].
\]

All in all, we get that the natural transformation \( \tilde{\text{ch}}_{\text{GL}} \) is homotopic to the composite

\[
\text{BGL}_x(A) \to \nu \text{CE}^Q(\mathfrak{gl}_x(A)) \to \text{HC}_k^\ast(A)[1].
\]

Passing to the tangent morphism and using the Beck-Chevalley natural transformation, we find

\[
T : \mathfrak{gl}_x(A)[1] \to \nu \ell \text{CE}^Q(\mathfrak{gl}_x(A)) \to \theta \ell^2 \text{CE}^Q(\mathfrak{gl}_x(A)) \to \theta \ell^2 \text{HC}_k^\ast(A)[1] \to \ell^2 \text{HC}_k^\ast(A)[1] \simeq \text{HC}_k^\ast(A)[1].
\]

**Lemma 4.2.2.** Let \( R \) be a (possibly non-unital) \( k \)-algebra and \( A \) be a (possibly non-unital) connective dg-algebra over \( k \). The natural morphism

\[
\ell \text{CE}^Q(\mathfrak{g}_R(\tilde{A})) \to \text{CE}^k_R(\mathfrak{g}_R(A))
\]

induced by the lax monoidal structure on \( \ell^0 \) is an equivalence.

**Remark 4.2.3.** We have \( \mathfrak{g}_R(A \otimes_k -) \simeq (R \otimes_k A) \otimes_k - \). Up to replacing \( A \) with \( R \otimes_k A \), we can assume that \( R = k \). Note that \( \mathfrak{g}_k = \mathfrak{gl}_1 \) computes the underlying dg-Lie algebra of a given dg-algebra.
Proposition 2.3.9

We fix a discrete algebra and write $A$. By adjunction, it suffices to identify the corresponding morphism $\xi_A: \text{CE}_k^k(A) \to \text{CE}_k^k(A)$ obtained by adding a unit. It actually suffices to understand the morphism

This construction is functorial in $A \in \text{dgAlg}_{k}^{\leq 0, \nu}$ and moreover and the functor $A \mapsto \text{CE}_k^k(A)$ preserves geometric realizations. Since every connective dg-algebra can be obtained as the geometric realization of a diagram of discrete algebras, the natural transformation $\xi$ is determined by its values on discrete algebras.

We fix $A$ a discrete algebra and write $L$ for its underlying Lie algebra. Consider the Lie algebra $L^2 = L \oplus L$ underlying the algebra $A^2$. The diagonal morphism $A \to A^2$ therefore leads (by functoriality) to a commutative diagram

The vertical morphisms identify with the coproduct of $\text{CE}_k^k(L)$ through the isomorphism

Hence, it follows that $\xi_A$ is a morphism of coalgebras. Moreover, the fact that Malcev’s quasi-isomorphism (see Proposition 1.3.7) is compatible with the standard filtrations implies that so is $\xi_A$. As a
consequence, the natural transformation $\xi$ lifts to a self natural transformation $\zeta: F \Rightarrow F$ of the functor $F: \text{Alg}_k \to \text{Lie}_k$ mapping an algebra to its underlying Lie algebra.

By forgetting down to the category of small sets, we obtain a self natural transformation (still denoted $\zeta$) of the forgetful functor $G: \text{Alg}_k \to \text{Sets}$. The functor $G$ is representable by the non-unital algebra $k[t]^{\geq 1}$ of polynomials $P$ over $k$ such that $P(0) = 0$. By the Yoneda lemma, the natural transformation $\zeta$ is determined by $P \in k[t]^{\geq 1}$. The fact that $\zeta$ is $k$-linear implies that $P$ is of degree 1, and the fact that it preserves the Lie brackets implies that $P = at$ with $a^2 = a$. In particular, the natural transformation $\zeta$ (and therefore also $\xi$) is either the identity or the 0 transformation. Since $\xi$ is the image by $\xi^3$ of the Malcev equivalence $Q[\mathcal{BG}_k(A_-)] \simeq \text{CE}_q^G(g_k(A_-))$, it certainly cannot vanish. □

This concludes the proof of Theorem 4.2.1.
