ABSTRACT

The activity concentration and Annual Effective doses of \(^{40}K, ^{226}Ra, \) and \(^{232}Th\) in some edible mushroom species (Cantharelluscibarius, Agaricuscampestris, Termitomycesrobustus) found in three Local Government Areas of Benue state-Nigeria were determined using Gamma Spectrometry; the 1460KeV gamma-radiation of \(^{40}K\) was used to determine the concentration of \(^{40}K\), gamma transition energy of 1764.5KeV \(^{214}Bi\) was used to determine the concentration of \(^{226}R\), while the gamma transition energy of 2614KeV \(^{208}TI\) was used to determine the concentration of \(^{232}Th\). The activity concentration due to \(^{226}Ra\), \(^{232}Th\) and \(^{40}K\) in the samples ranged from 10.06 ± 1.6 - 14.19 ± 3.01Bqkg\(^{-1}\); 10.88 ± 2.65 to 15.38 ± 4.30Bqkg\(^{-1}\) and 202.31 ± 1.4 to 318.44 ± 3.20Bqkg\(^{-1}\) respectively; the highest activity due to \(^{226}Ra\) was found in Termitomycesrobustus grown in Gboko; that due to \(^{232}Th\) was recorded in Agaricuscampestris grown in Buruku L.G.A., while the highest activity concentration due to \(^{40}K\) was recorded in Termitomycesrobustus found in Buruku. Generally, \(^{40}K\) recorded the highest activity concentration in each mushroom species examined. Annual Effective Dose from these species sampled ranges from 0.0006952 mSv y\(^{-1}\) (in Makurdi- Termitomycesrobustus species) - 0.0008467 mSv y\(^{-1}\) (in Buruku Termitomycesrobustus species). The average effective dose value of 0.00788 ± 0.000186 mSv y\(^{-1}\) obtained in this work is below the maximum permissible level established by ICRP (1996). Thus, these mushrooms species will not pose any apparent risk to human health.

Keywords: Gamma Spectrometry, Radionuclide, Mushroom, Activity Concentration, Annual effective dose

1.0 INTRODUCTION

Plants are one of the sources for elements and radionuclides for a human. Measuring the radioactivity concentration of an environment, food products from plants such as mushroom is of importance in determining the radiation levels to which consumers of such food is exposed to directly or indirectly. Mushrooms are a special group of fungi which are saprophyticnature. They lack chlorophyll and consequently cannot use solar energy in manufacturing their food. Their mode of nutrition is by producing a wide range of enzymes that can break down complex substances after which they can absorb the soluble substances so formed\(^1\). Consumption of edible mushroom lead to improved nutritional intake of humans, because mushroom contains vitamins such as thiamine riboflavin, ascorbic acid, ergosterine, niacin, vitamins C, B\(_1\), B\(_5\) and vitamin D,
fat, iron, phosphorus which produce a range of metabolites of intense interest to the nutraceutical, pharmaceutical (e.g. antitumor) and food (e.g. flavor compound) industries.

Most species of mushroom if not all, contain biologically active polysaccharides, these include edible/medicinal species like *Pleurotus Ostreatus*; poisonous species such as *Amanita Phalloides* and *Hallucinogenic* species like *Psilocye Mexicana*. According to the traditional beliefs among native people, consumption of *Pleurotus* species of mushrooms was believed to prevent high blood pressure, impact long life and vigour while also acting as an aphrodisiac, hypertensive, immunomodulatory and antitumor activities of polysaccharide-protein complex (PSPC) because of its high content of retene (C_{18}H_{18}).

Giving attention to the studies of radionuclides in mushroom has drawn the attention of many scholars over the ages, for instance, Kuwahara et al., (2005) and Bazala et al., (2008) found out that different species of mushroom have the capacity to retain high concentrations of radionuclides and metals from the soil. Some radionuclides easily accumulated by mushroom according to these authors are 40K, 137Cs, 226Ra and 228Ra. De Castro et al., (2012) in their study on “artificial (137Cs) and natural radioactivity (40K, 226Ra, 228Ra)” determined in 17 mushroom sampled from 3 commercial edible mushroom species in São Paulo, Brazil adducting the techniques developed by Figueira et al., (2007) as quoted by Silva et al., (2016). De Castro et al., (2012) concluded that the gamma spectrometry methodology allowed the determination of 137Cs, 40K, 226Ra and 228Ra levels present on edible mushroom samples with better precision and accuracy.

Activity concentration of mushrooms is affected by several factors such as species, contamination of soil, time of the disaster and the soil horizon from which species takes nutrients and moisture.

The rural communities in Benue State consume a lot of natural and locally grown mushrooms, and as a result of the wide spreads of radioactive isotopes, quantitative determination of radionuclides in these mushrooms is of scientific interest to determine the gamma radioactivity levels in selected edible mushroom species consumed in three selected location within the State in Nigeria. Hence, to estimate the activity concentration (Bq/kg) of radionuclides; the annual effective dose (µSv/y) from ingesting the mushroom samples; also to determine whether the concentration activity of the radionuclides in these mushrooms pose any threat to human health.
2.0 Materials and Methods

For this work, three (3) different species of edible mushrooms which includes: *Cantharelluscibarius*, *Agaricuscampestris*, *Termitomycesrobustus* were obtained from three selected Local Government Areas: Gboko (7.3368\(^\circ\)N, 9.0018\(^\circ\)E), Makurdi (7.7322\(^\circ\)N, 8.5391\(^\circ\)E) and Buruku (7.4178\(^\circ\)N, 9.2231\(^\circ\)E) all within Benue State Nigeria; these samples were labeled according to sampling sites. Major materials used include Lyophilizer, Domestic blender, spring balance, Thallium – doped sodium iodide (NaI (Tl)) scintillation detector, Multi-channel Analyzer.

These Samples were washed, lyophilised using the lyophilizer at the Chemistry Department, Fountain University, Osogbo, Osun State, Nigeria for 12hrs for dehydration. A mechanical blender was used to pulverise the dried samples into powder. Nine samples were prepared. Twenty (20g) of each dried mushrooms were packaged in polyethene beakers, sealed and allowed to stand for at least 28 days to establish radioactive equilibrium.

2.1 Determination of Activity Concentration and Effective Annual Dose

Gamma spectrometry measurements were carried out at the Radioactivity Measurement Laboratory, Department of Pure and Applied Physics, Ladoke Akintola University of Technology Ogbomoso, Oyo State Nigeria, using a calibrated NaI (TI) and a well-shielded detector coupled to a computer resident quantum MCA2100R Multichannel analyser for 36,000s. The detector efficiency was at 98.67%. To determine the concentration of \(^{40}\)K in the sample, 1460KeV gamma-radiation of \(^{40}\)K calibration was calibrated. The gamma transition energy of 1764.5KeV \(^{214}\)Bi was established to determine the concentration of \(^{226}\)Ra; gamma transition energy of 2614KeV \(^{208}\)Th was used to determine the concentration of \(^{232}\)Th. The efficiency calibration of the detector was done using a reference standard mixed source traceable to Analytical Quality Control Service (AQCS, USA).

The activity concentration, \(A\) (Bq/kg) of the radionuclides were computed and obtained using the equation;

\[
A(\text{BqKg}^{-1}) = \frac{C_s}{\epsilon P Y M_s}
\]
Where, $C_s$ = Count rate under each photo peak due to each radionuclide, $P_y$ = Absolute transition probability of the specific gamma field, $\xi$ = Detector efficiency for the specific $\gamma$-ray energy, $M_s$ = Mass of the sample (dry mass).

The samples collected from Gboko, Makurdi and Buruku were coded as SG, SM, and SB respectively.

To assess the radiological health risk associated with the consumption of the mushrooms in the researched areas, the average annual committed effective dose ($E_{ave}$) was estimated using the equation

$$E_{ave} = C_r \times DCF_{ing} \times A_s$$

Where, $DCF_{ing}$ is the dose convection factor for ingestion, for each radionuclide (i.e., $4.5 \times 10^{-5}$mSv Bq$^{-1}$, $2.3 \times 10^{-4}$mSv Bq$^{-1}$ and $6.2 \times 10^{-6}$mSv Bq$^{-1}$ for $^{226}$Ra, $^{232}$Th and $^{40}$K respectively) for an adult$^{16,17}$, $C_r$ = consumption rate from intake of naturally occurring radioactive materials in mushrooms and $A_s$ is the activity concentration in the sample.

### 3.0 Results and Discussions

The activity concentration of $^{40}$K varied from 202.31 ± 1.4 to 318.44 ± 3.2Bq kg$^{-1}$with an average value of 235.76 ± 27.32Bq kg$^{-1}$. The activity concentration of $^{226}$Ra in the mushroom collected ranged from 10.06 ± 1.6 to 14.19 ± 3.01Bq kg$^{-1}$ with an average value of 12.58 ± 3.58 Bq kg$^{-1}$ as indicated in table 1. The highest activity concentration of $^{226}$Ra was recorded for *Termitomycesrobustus* found in Gboko local government (SG3) while *Agaricuscampestris* found in Buruku local government (SB8) had the lowest activity concentration of $^{226}$Ra. For the activity concentration of $^{232}$Th, it varied from 10.88 ± 2.65 to 15.38 ± 4.3 Bq kg$^{-1}$ with an average value of 12.61±3.0 Bq kg$^{-1}$in the mushrooms. The highest and lowest activity concentration was recorded for *Agaricuscampestris* found in Buruku local government (SB8), and *Agaricuscampestris* found in Gboko local government (SG2) respectively. $^{40}$K recorded the highest activity concentration in all the mushrooms compared to the activity concentration of $^{226}$Ra and $^{232}$Th observed.

### Table 1: Activity concentrations of $^{40}$K, $^{226}$Ra and $^{232}$Th in the mushroom species collected.

| Samples Codes | Sample name          | Location (L.G.A.) | Activity Concentrations ($^{40}$K, $^{226}$Ra, $^{232}$Th) | Annual Committed Effective Dose for 1kg y$^{-1}$ (mSv y$^{-1}$) |

| SM$_5$        | Agaricuscampestris   | Makurdi           | 223.16 ± 15.77 13.50 ± 6.38 12.54 ± 3.64                 | 0.008048                                                   |
| SM$_6$        | Termitomycesrobustus | Makurdi           | 212.16 ± 70.01 10.25 ± 3.99 12.03 ± 5.16                 | 0.006952                                                   |
Cantharellus cibarius Buruku 282.36 $\pm$ 1.10 13.92 $\pm$ 3.0 12.06 $\pm$ 1.40 0.008422

Agaricus campestris Buruku 202.31 $\pm$ 1.40 10.06 $\pm$ 1.6 15.38 $\pm$ 4.30 0.007609

Termitomyces robustus Buruku 318.44 $\pm$ 3.20 12.14 $\pm$ 2.2 13.45 $\pm$ 1.20 0.008467

Termitomyces robustus found in Buruku (SB3) had the highest activity concentration of $^{40}$K, next to it was Cantharellus cibarius, and the lowest was recorded in Agaricus campestris (SB8). In Gboko, Agaricus campestris has the highest records of $^{40}$K concentration with a value of 228.10 ± 45.75 Bq/kg while Termitomyces robustus has the lowest activity concentration of $^{40}$K with a value of 204.16 ± 64.01 Bq/kg.

Termitomyces robustus and Agaricus campestris have highest and lowest activity concentrations of $^{226}$Ra with values of 14.19 ± 3.01 Bq/kg and 12.25 ± 3.59 Bq/kg respectively. Agaricus campestris and Termitomyces robustus were discovered to have the lowest and highest $^{232}$Th concentration in Gboko 10.88 ± 2.65 Bq/kg and 13.83 ± 2.08 Bq/kg respectively.

Figure 2: Activity Concentration (Bq/kg) of Mushroom species from Gboko

The result obtained for Makurdi presented in figure 2., indicate lowest values of $^{40}$K, $^{226}$Ra and $^{232}$Th found in Termitomyces robustus, accorded values of 212.16 ± 70.01 Bq/kg, 10.25 ± 3.99 Bq/kg and 12.03 ± 5.16 Bq/kg respectively. As shown in figure 2 also, the highest value of $^{40}$K was found in Cantharellus cibarius, while Agaricus campestris has the highest values of $^{238}$Ra and $^{232}$Th with values of 235.6 ± 3.1Bq/kg, 13.50 ± 6.38 Bq/kg and 12.54 ± 3.64 Bq kg$^{-1}$ respectively.
In Buruku Local Government Area, figure 4 shows that *Termitomyces robustus*, recorded the highest $^{40}$K concentration of 318.44 ± 3.2 Bq kg$^{-1}$ while *Agaricus campestris* shows the lowest activity concentration for $^{40}$K and $^{226}$Ra with a value of 202.31 ± 1.40 Bq kg$^{-1}$ and 10.06 ± 1.60 respectively.

*Cantharellus cibarius* and *Agaricus campestris* are found to have the lowest and highest $^{232}$Th concentration for Buruku with values of 12.06 ± 1.4 Bq kg$^{-1}$ and 15.38 ± 4.3 Bq kg$^{-1}$ respectively.

The activity concentration of $^{40}$K is usually high compared to $^{238}$Ra and $^{232}$Th, and forms an integral part of all organic constituents. The high activity concentration of $^{40}$K recorded for *Termitomyces robustus* among all the samples could aid in its therapeutic purposes for the treatment of High Blood Pressure as patients with High Blood Pressures have low concentration of Potassium in their blood stream.

The mean activity concentration of the radionuclide in the various mushroom samples is shown in Table 2.

**Table 2: Mean values of activity concentrations (Bq Kg$^{-1}$) of species**

| Sample species            | K-40         | Ra-226       | Th-232       |
|---------------------------|--------------|--------------|--------------|
| *Cantharellus cibarius*   | 244.46±15.23 | 13.61±3.82   | 11.79±2.65   |
| *Agaricus campestris*     | 217.88±20.97 | 11.93±3.86   | 12.93±3.53   |
| *Termitomyces robustus*   | **244.92±45.74** | 12.19±3.06   | 13.10±2.81   |

**Discussions**

The calculated average annual committed effective dose to any individual due to the ingestion of natural radionuclides for these mushrooms species researched is far below the average radiation dose of 1 mSv/y (ICRP 1996) and 0.3 mSv/y (UNSCEAR 2000). The threshold consumption rate being the limiting value of AACED become greater than 1mSv for any of these species sampled; as indicated in Table 3, the lower the AACED, the greater the threshold value for the mushroom. This provides a baseline data indicating that an adult with consumption rate below the threshold values would be exposed to insignificant radiological health risk while those whose consumption rate is higher are prone to significant radiological health risk.
Comparing these results with other published data, in Ekiti State Nigeria, *Termitomyces robustus* being a species considered in this study presents an average activity concentration of 339.05 ± 87.76 of $^{40}$K, 15.78 ± 4.98 of $^{226}$Ra and 14.31 ± 6.01 of $^{232}$Th. Data from other countries indicates that the average activity concentration values obtained for $^{238}$U ($^{226}$Ra), $^{232}$Th and $^{40}$K in this study are less than the published work as shown by De Castro, (2012) in *Agaricus species* obtained 1215 ±5 of $^{40}$K, 18 ± 3 for $^{226}$Ra and 38.1 ± 1.2 for $^{228}$Ra.

These variations in the activity concentrations of this research work with those from other countries may be as result of differences in the geological location of the fungi and the radiochemical composition of the soils in which these mushrooms are grown or cultivated since the levels of activity concentration of natural radionuclides are not normalized across the globe and the species' ability to efficiently absorb certain natural radionuclide more than others and nature of soil.

### Table 3: Average annual committed effective dose and threshold consumption rate associated with each sample

### 4.0 CONCLUSION

The natural radionuclide contents of three (3) mushroom species from three (3) different locations in Benue State Nigeria have been analysed by means of Gamma Spectrometry with NaI (TI) detector. The results obtained from this work indicated that $^{40}$K recorded the highest activity concentration in all the mushrooms compared to the activity concentration of $^{226}$Ra and $^{232}$Th observed. The activity concentration of $^{40}$K varied from 202.31 ± 1.4 to 318.44 ± 3.2 Bq/kg with an average value of 235.76 ± 27.32 Bq/kg. The average annual committed effective dose were found to be lower than the average world value of 0.3 mSv/y as recommended by UNSCEAR (2000) and 1 mSv/y as recommended by ICRP (1996)18.

The threshold consumption rate for each mushroom; annual committed effective doses were found to be below the maximum permissible levels established by national legislations ICRP and UNSCEAR.
Thus these mushroom species can normally be consumed by the populace without any apparent risks to their health.
