ARTICLE INFO

Keywords: Psychoactive Substance abuse High school College University

ABSTRACT

Background: Substance uses were seen in 18–25 years old age groups who are more than 40% world population, from which Africa was the region with the highest proportion accounting 60% in 2016. This review aimed to assess the burden of substance abuse among students in Ethiopia.

Methods: A comprehensive search was conducted in PubMed/Medline; Science direct and African Online Journal without language and date restriction. The Heterogeneity among the included studies was checked with forest plot, χ2 test, I2 test, and the p-values. All cross-sectional studies reporting rate of prevalence of psychoactive substance among students were included and the rest were excluded.

Result: A total of 545 articles were identified from different databases and 42 articles were selected for evaluation. Twenty-nine Articles with 22,012 participants were included. The overall prevalence of psychoactive substance abuse was 32.28% (95% confidence interval (CI): 26.74 to 37.82).

Conclusion: The review revealed that one-third of the high school and higher education students used different psychoactive substances in Ethiopia.

Registration: This Systematic Review and Meta-Analysis was registered in Prospero international prospective register of systemic reviews (CRD42020146656) on April 28/2020.

1. Introduction

Psychoactive substance abuse is the consumption of substances or deliberate use of substances for the purpose other than its intended purpose without the supervision of a physician or medical practitioner [1].

According to the United Nations Office on Drugs and Crime (UNODC) report, the highest levels of drug uses were seen in 18–25 years old age groups who are more than 40% world population and from which Europe was the region with the lowest proportion of its population under 25 (27%) and Africa was the highest proportion accounting for sixty percent in 2016 [2].

Recent global statistics on Alcohol consumption, daily tobacco smoking, and Illicit drug use report revealed that the prevalence of alcohol consumption, Tobacco smoking, cannabis and opioid use among the adult population aged greater than 15 years were 18.4%, 15.2%, 3.8%, and 0.77% respectively. Alcohol consumption was the highest in the European region and the lowest was reported in North Africa and the Middle East [3].

There were approximately one billion Tobacco smokers globally where the highest smokers found in China (268.3 million) followed by India (104.2 million) and Indonesia (53.4 million). The North American region counts for the highest drug illicit substances including cannabis, opioid, and cocaine [3].

Historically, cannabis use and cultivation have been prevalent in Africa, Central Europe, South Asia, and China [3–8]. Global reports showed that cannabis is the most commonly used illicit drug where the prevalence is higher among Western Central Africa, North America, and Oceania [2,4,5]. According to a global estimate from different countries, 13.8 million students aged 15–16 years old used cannabis in the last 12 months in 2016 with the highest in European school students where Estonia and Poland accounting the highest prevalence [3,5].

A systemic review done in Sub-Saharan African countries showed that the prevalence of substance abuse varies with the types of substance within the region [8]. The pooled prevalence of substance abuse among adolescents in the Sub-Saharan region was 41.6% with the highest in Central Africa (55.5%) followed by East Africa (48.99%) and West Africa (38.3%) [8].

The pooled prevalence of alcohol consumption was very high in Sub-Saharan African region (32.77%), from which Southern Africa region accounted for the highest prevalence (40.82%) followed by East Africa (34.25%) whereas cannabis abuse among Adolescents was the highest in East Africa (28.9%) followed by Southern Africa (25.7%) and West Africa (0.70%) [8].

The overall prevalence of substance use among University students in Ethiopia ranged from 16.7% to 72.6% [1,8–26] whereas the overall prevalence of substance use varies from 24.6% to 47.9% among high school students [27–31]. The lifetime prevalence of Khat chewing, Alcohol consumption and cigarette smoking varies from 7% to 65%, 13%–28%, 4.8%–5.4% and 4.2–50%, 0.8 to 67 and 0.8 to 12 among college and University students respectively [1,9,11,13–16,19–23,26,31–35].

A systematic review conducted among University Students in Ethiopia on the burden of Khat chewing showed that the prevalence of Khat chewing among University students was 23.22% [36].

There were about 190 million substance users worldwide and from which 40 million were identified with severe illness and disorders each year. Substance abuse leads to decrease academic performance, increase risk of unprotected sex and sexually transmitted infections, increase unwanted pregnancy and abortion and also it is the major cause of psychiatric disorders like depression and suicide attempts [2–4,6,8,9,17,25,32,36–49]. The global burden of disease showed that substance abuse was responsible for more than 170,000 deaths in the year 2005–2015 alone, and from which opioid use disorders accounted for the majority of drug use related deaths in 2015 [4].

Studies since the 1990s showed that cannabis use before the age of 15 years predicts early school-leaving and this persists after adjustment for confounders [50]. Longitudinal studies have also shown that early initiation of heavy cannabis use is associated with lower income, lower college degree completion, and greater need for economic assistance, unemployment, and use of other drugs [5,47,48].

Currently, substance abuse is a neglected health problem in developing countries which affects the younger and productive age groups who are the gear pivots of development of a nation. A number of observational studies were conducted among students in Ethiopia in different regions of the country. However, the pooled prevalence and risk factors of psychoactive substance abuse among students in Ethiopia, particularly in high school students is uncertain and a topic of debate. Therefore; this systemic review aimed to investigate the national prevalence and reasons of substance abuse among Ethiopian students.

2. Methods

2.1. Protocol and registration

The systematic review and meta-analysis was conducted based on the Preferred Reporting Items for Systematic and meta-analysis (PRISMA) protocols [51], and the Meta-Analysis Of Observational Studies in Epidemiology (MOOSE) checklist [52]. This systematic review and meta-analysis was registered in Prospero’s international prospective register of systematic reviews (CRD42020146656) on April 28/2020.

2.2. Inclusion and exclusion criteria

2.2.1. Inclusion criteria

All cross-sectional studies reporting prevalence and risk factors of psychoactive substance abuse among high school, college and University students in Ethiopia without date and language restriction were included.

2.2.2. Exclusion criteria

Studies that didn’t report prevalence of psychoactive substances, studies on prevalence of substance among general population, street children and studies conducted abroad, systemic review, case reports and clinical reviews were excluded.

2.3. Outcomes of interest

2.3.1. Primary outcomes

The primary outcomes of interest were prevalence of Khat, Alcohol, smoking among students Secondary outcomes.

Prevalence of reasons of substance abuse among students was the secondary outcome.

2.4. Search strategy

The search strategy was intended to explore all available published and unpublished studies on psychoactive substance abuse among Ethiopian students without language and date restriction. A three steps search strategy was employed in this review on November 2020 and the search strategy was updated in June 16, 2021. An initial search on PubMed/Medline, Science direct and African Online Journal was carried out followed by an analysis of the text words contained in Title/Abstract and indexed terms. A second search was undertaken by combining free text words and indexed terms with Boolean operators. The third search was conducted with the reference lists of all identified reports and articles for additional studies. Finally, the additional and grey literature search was conducted on Google scholars. The search strategy was used as follows by modifying the Mesh terms and combing Boolean operators: student OR high School student OR college student OR university student OR compass student AND substance OR alcohol OR Khat OR Catha Edulis OR Chat OR mirra OR mairungi OR Cigarrate OR shisha OR psychoactive substance OR cocaine OR opioids OR marijuana AND addiction OR abuse OR burden OR Magnitude OR prevalence. The result of the search strategy was presented with the Prisma flow chart (Fig. 1).

2.5. Data extraction

The data from each study were extracted with two independent authors with a customized format. The disagreements between the two independent authors were resolved by the third Author. The extracted data included: Author names, country, date of publication, sample size, the prevalence of Khat chewing, alcohol consumption, cigarette smoking, prevalence of the commonest reason of psychoactive substance abuse, region where the study is conducted, study design and types of substance abuse. Finally, the data were then imported for analysis in R software version 3.6.1 and STATA 14.

2.6. Assessment of methodological quality

Articles identified for retrieval were assessed by two independent Authors for methodological quality prior to inclusion in the review using a standardized critical appraisal Tool adapted from the Joanna Briggs Institute (Supplemental Table 1). The disagreements between the Authors appraising the articles were resolved through discussion. Articles with average scores greater than fifty percent were included for data extraction. The quality of this systematic review was evaluated with the Assessment of Multiple Systematic Reviews 2 (AMSTAR2) checklist [53].

2.7. Data analysis

The pooled prevalence of substance abuse was determined with a random effect model as there was substantial heterogeneity. The Heterogeneity among the included studies was checked with forest plot, y2 test, I² test, and the p-values. Substantial heterogeneity among the included studies was investigated with subgroup analysis and meta-regression. Sensitivity analysis was done to evaluate the influential studies and further analysis was made after removing the outliers.

Publication bias was checked with a funnel plot and the objective
Records identified in PubMed/Medline (5), Science direct (406), African Online Journal (98)

Records after duplicates removed (n = 545)

Records screened (n = 42)

diagnostic test was conducted with Egger’s correlation, Begg’s regression tests.

3. Results

3.1. Selection of studies

A total of 545 articles were identified from different databases with an initial search. Forty-two articles were selected for evaluation after the successive screening. Twenty-nine Articles with 22,012 participants assessing the prevalence of psychoactive substance abuse as a primary outcome among students were included and the rest were excluded. The included studies were published from 2004 to 2019 with sample size ranged from 118 to 3268.

All of the included studies were cross-sectional studies and their methodological qualities were moderate to high. The majority of studies were from the Amhara regional state followed by Oromia and SNNPR. There was no study from Afar and Benshangul Gumuz regional states. The majority of included studies were conducted in Universities [17] followed by High Schools [8] and college [4]. Eighteen studies tried to assess the prevalence and associated factors of more than two substance uses, twelve studies assess only the prevalence and associated factors of Khat among students and one study assessed the prevalence of Cigarette smoking alone.

Three studies assessed the prevalence of cannabis and its varieties use including Hashish, Shisha, and Marijuana among students. One study reported the use of narcotics, benzodiazepines, hashish and benzene among university students.

The majority of studies reported different types of risk factors of

substance abuse among students including Family substance use, peer pressure, poor academic performance, dissatisfaction, and socio-demographic characteristics (Table 1).

### 3.3. Meta-Analysis

Twenty Nine studies assessing different types of substance abuse among high School, College, and University students were identified. The overall prevalence of psychoactive substance among students was 32.28% (95% confidence interval (CI): 26.74 to 37.82, 29 studies, 22,012 participants) (Fig. 2).

The Subgroup analysis revealed that the lifetime prevalence of more than two substance abuse was 39.34% (95% confidence interval (CI): 30.33 to 48.35, 16 studies, 9176 participants whereas the prevalence of Khat and cigarette smoking was 22.91% (95% confidence interval (CI): 18.65 to 27.17 and 29.53% (95% confidence interval (CI): 23.10 to 37.97) respectively (Fig. 3).

Besides, the Meta-Analysis revealed that the prevalence of psychoactive substance abuse was highest in Somalia region, 52.93% (95% confidence interval (CI): 40.10 to 65.97) followed by Harari 43.72% (95% confidence interval (CI): 38.10 to 50.35) (Supplemental Fig. 1).

The subgroup analysis showed that the highest prevalence of psychoactive substance abuse among students was in University and High School students, 37.18% (95% confidence interval (CI): 29.21 to 45.16, 17 studies, 13956 participants) and 28.35% (95% confidence interval (CI): 17.34 to 39.36, 9 studies, 6594 participants) respectively (Fig. 4).

The Meta-Analysis showed that the prevalence of reasons among students for chewing Khat were reading/concentration, enjoyment and peer pressure: 45.83% (95% confidence interval (CI): 40.02 to 51.65), 34.77% (95% confidence interval (CI): 19.36 to 50.17) and 27.51% (95% confidence interval (CI): 18.84 to 36.38) respectively (Fig. 5). Where as enjoyment was the main reason for Alcohol consumption followed by peer pressure. (supplemental Fig. 2).

### 3.4. Publication bias and sensitivity analysis

The funnel plot for evaluation of publication bias didn’t show asymmetric funnel plot. Besides, the rank correlation and Egger’s regression test didn’t show a significant difference for small study effect (p-value > 0.3051 and 0.090 respectively) (Fig. 6). Sensitivity analysis didn’t show influential studies on the summary effect (Supplemental Table 3).

### 4. Discussion

The overall pooled prevalence of psychoactive substance abuse in

**Fig. 3.** Forest plot for subgroup analysis of prevalence of substance abuse among students by types of substance: The midpoint of each line illustrates the prevalence; the horizontal line indicates the confidence interval, and the diamond shows the pooled prevalence.
This systematic review and Meta-analysis was 32% (95% confidence interval (CI): 27 to 38, 29 studies, 22,012 participants). The finding of this review is less compared to another meta-analysis conducted in Sub-Saharan region (41.6%), in Central Africa (55.5%), East Africa (48.99%) and West Africa (38.3%) [8]. The possible reason for the noted difference might be the access and availability of different psychoactive substances and the influence of cultural and religious norms of the society that condemns the use of psychoactive substances. Besides this, the difference in the total number of literature review plays a role in the prevalence difference.

Based on the number of substances consumed the lifetime prevalence of more than two substance abuse was 39% (95% confidence interval (CI), 30 to 48). This finding is in line with studies conducted among college and university students in Ethiopia [1,9-11,13-16,19-23,26,31-35].

The systemic review and meta-analysis revealed that the lifetime prevalence of Khat chewing was found to be 23% (95% confidence interval (CI) 19 to 27) which is in line another systematic review and meta-analysis conducted on the prevalence of Khat chewing among university students in Ethiopia, 23.22% [36].

In this systematic review and meta-analysis, the lifetime prevalence of cigarette smoking was found to be 30% (95% confidence interval (CI) 23 to 37). Although this meta-analysis and systematic review concern the epidemiological burden of psychoactive substance abuse among Ethiopian students, it is known that several influencing factors played a great role in the burden.

The analysis of overall lifetime prevalence of psychoactive substance abuse among the regions revealed that the highest pooled prevalence of psychoactive substance abuse was found in Somalia region 53% (95% confidence interval (CI): 49 to 57) followed by Harari 43% (95% confidence interval (CI): 20 to 69) and this discrepancy might be due to accessibility psychoactive substance, social norms of the locality, geographic location and religious perspectives which might be acceptable in taking certain psychoactive substances.

4.1. Comparison with other meta-analysis

This systematic review and Meta-Analysis is different from the
The previous Meta-Analysis conducted among University students in several ways. First of all, this systematic review was mainly intended to investigate the prevalence of psychoactive substances among high school students which is not addressed previously. The previous Meta-Analysis was conducted in a specific substance like Alcohol, Khat, and Cigarette smoking among University students only unlike this systematic review which investigates the overall and specific psychoactive substance abuse among students above high school. Secondly, no systematic review and Meta-Analysis is investigating on the prevalence of psychoactive substance among high school and college students who are the gear changers of community development.

4.2. Quality of evidence

The systematic review and meta-analysis included many studies with an adequate sample size. The methodological quality of included studies was moderate to high as evaluated with the Joanna Briggs Institute assessment tool for meta-analysis of observational studies. However, the quality of publication bias was assessed using funnel plots and the Egger test.

Fig. 5. Forest plot for subgroup analysis of prevalence of Khat chewing among students by reasons: The midpoint of each line illustrates the prevalence; the horizontal line indicates the confidence interval, and the diamond shows the pooled prevalence.

Fig. 6. Funnel plot to assess publication bias: The vertical line indicates the effect size whereas the diagonal line indicates the precision of individual studies with a 95% confidence interval.
substantial heterogeneity associated with differences in included studies by sample size, design, and location could affect the allover quality of evidence.

4.3. Limitation of the study

The review incorporated plenty of studies with a large number of participants but the majority of studies included in this review didn’t report data on risk factors to investigate the reasons for psychoactive substance use among students.

4.4. Implication for policy

Body of evidence revealed that the prevalence of psychoactive substances among students is very high. It is very shocking having the prevalence of psychoactive substances among high school students who are supposed to handover and sustain the countries development. Technological innovation, discovery, and societal development are not expected if the young productive populations are suffered from psychoactive substances. Therefore, different strategies are required as early as possible to prevent substance abuse among students. This could be achieved by awareness creation about the impacts of substance abuse, the anti-drug club at the school level, the inclusion of substance abuse and its impacts in the curriculum, regulations on substance production and advertisement.

4.5. Implication for further research

The meta-analysis revealed that the prevalence of psychoactive substances among students was very high and the main reasons for substance use were identified. However, the included studies were too heterogeneous, and cross-sectional studies also don’t show a temporal relationship between mortality and its determinants. Therefore, further observational and randomized controlled trials are in demand for a relationship between mortality and its determinants. Therefore, further observational and randomized controlled trials are in demand to investigate the reasons for psychoactive substance use among students.

5. Conclusion

The review revealed that one-third of the high school and higher education students in Ethiopia have reported using the different psychoactive substances among students by stratifying the possible independent predictors. However, the included studies were too heterogeneous, and cross-sectional studies also don’t show a temporal relationship between mortality and its determinants. Therefore, further observational and randomized controlled trials are in demand for a specific group of patients by stratifying the possible independent predictors.

Acknowledgments

The authors would like to acknowledge Dilla University for technical support and encouragement to carry out the project.

Appendix A. Supplementary data

Supplementary data to this article can be found online at https://doi.org/10.1016/j.amsu.2021.102790.

Ethical approval

Not applicable.

Sources of funding

No funding was received.

Author contribution

Semagn Mekonnen Abate conceived the idea and design of the project. Semagn Mekonnen Abate and Yigrem Ali Chekole, Solomon Yimer Minaye involved in data management, entry, analysis interpretation, and manuscript preparation. All authors read and approved the final manuscript.

Consent

Consent was not applicable as it was systematic review and meta-analysis.

Registration of research studies

This review was registered in Prospero international prospective register of systematic reviews (CRD42020146656).
