One of the key ingredients of physics beyond the standard model is widely believed to be a symmetry between the fermions and the bosons known as supersymmetry. The reason for this is that the milder divergence structure of field theories with this symmetry may explain why the electroweak scale (or the Higgs mass) is stable under radiative corrections. Two other reasons adding to this belief are: (i) a way to understand the origin of the electroweak symmetry breaking as a consequence of radiative corrections and (ii) the particle content of the minimal supersymmetric model that leads in a natural way to the unification of the three gauge couplings of the standard model at a high scale. This last observation suggests that at scales close to the Planck scale, all matter and all forces may unify into a single matter and a single force leading to a supersymmetric grand unified theory. It is the purpose of these lectures to provide a pedagogical discussion of the various kinds of supersymmetric unified theories beyond the minimal supersymmetric standard model (MSSM) including SUSY GUTs and present a brief overview of their implications. Questions such as proton decay, R-parity violation, doublet triplet splitting etc. are discussed. Exhaustive discussion of SU(5) and SO(10) models and less detailed ones for other GUT models such as those based on E_6, SU(5) × SU(5), flipped SU(5) and SU(6) are presented.

Epilogue

1 Introduction

One of the fundamental new symmetries of nature that has been the subject of intense discussion in particle physics of the past decade is the symmetry between bosons and fermions, known as supersymmetry. This symmetry was introduced in the early 1970’s by Golfand, Likhtman, Akulov, Volkov, Wess and Zumino. In addition to the obvious fact that it provides the hope of an unified understanding of the two known forms of matter, the bosons and fermions, it has also provided a mechanism to solve two conceptual problems of the standard model, viz. the possible origin of the weak scale as well as its stability under quantum corrections. The recent developments in strings, which embody supersymmetry in an essential way also promise the fulfilment of the eternal dream of all physicists to find an ultimate theory of everything. It would thus appear that a large body of contemporary particle physicists have accepted that the theory of particles and forces must incorporate supersymmetry. This has important implications for the nature of new physics beyond the standard model which is a major focus of most research in particle physics
at the moment. Ultimate test of these ideas will of course come from the experi-
mental discovery of the superpartners of the standard model particles with
masses under a TeV and the standard model Higgs boson with mass less than
about 150 GeV.

Since supersymmetry transforms a boson to a fermion and vice versa, an
irreducible representation of supersymmetry will contain in it both fermions
and bosons. Therefore in a supersymmetric theory, all known particles are
accompanied by a superpartner which is a fermion if the known particle is a
boson and vice versa. For instance, the electron (e) supermultiplet will contain
its superpartner $\tilde{e}$, (called the selectron) which has spin zero. We will adopt
the notation that the superpartner of a particle will be denoted by the same
symbol as the particle with a ‘tilde’ as above. Furthermore, while supersym-
metry does not commute with the Lorentz transformations, it commutes with
all internal symmetries; as a result, all non-Lorentzian quantum numbers for
both the fermion and boson in the same supermultiplet are the same. As in the
case of all symmetries realized in the Wigner-Weyl mode, in the limit of exact
supersymmetry, all particles in the same supermultiplet will have the same
mass. Since this is contrary to what is observed in nature, supersymmetry has
to be a broken symmetry. An interesting feature of supersymmetric theories is
that the supersymmetry breaking terms are fixed by the requirement that the
mild divergence structure of the theory remains unaffected. One then has a
complete guide book for writing the local field theories with broken sup-
ersymmetry. We will not discuss the detailed introductory aspects of supersymmetry
that are needed to write the Lagrangian for these models and instead refer to
books and review articles on the subject\[1,2,3,4\]. Let us however give the bare
outlines of how one goes about writing the action for such models.

1.1 Brief introduction to the supersymmetric field theories

In order to write down the action for a supersymmetric field theory, let us start
by considering generic chiral fields denoted by $\Phi(x, \theta)$ with component fields
given by $(\phi, \psi)$ and gauge fields denoted by $V(x, \theta, \bar{\theta})$ with component gauge
and gaugino fields given by $(A^\mu, \lambda)$. The action in the superfield notation is

$$S = \int d^4x \int d^2\theta d^2\bar{\theta} \Phi^\dagger eV \Phi + \int d^4x \int d^2\theta (W(\Phi) + W_\lambda(V)W_\lambda(V)) + h.c.$$

In the above equation, the first term gives the gauge invariant kinetic energy
term for the matter fields $\Phi$; $W(\Phi)$ is a holomorphic function of $\Phi$ and is
called the superpotential; it leads to the Higgs potential of the usual gauge
field theories. Secondly, $W_\lambda(V) \equiv D^2DV$ where $D \equiv \partial_\theta - i\sigma_\theta \partial_x$, and the term
involving $W_\lambda (V)$ leads to the gauge invariant kinetic energy term for the gauge fields as well as for the gaugino fields. In terms of the component fields the lagrangian can be written as

$$L = L_g + L_{\text{matter}} + L_V - V(\phi)$$  \hspace{1cm} (2)

where

$$L_g = -\frac{1}{4} F^{\mu \nu} F_{\mu \nu} + \frac{1}{2} \bar{\lambda} \gamma^\mu i D_\mu \lambda$$

$$L_{\text{matter}} = |D_\mu \phi|^2 + \bar{\psi} \gamma^\mu i D_\mu \psi$$

$$L_V = \sqrt{2} g \bar{\lambda} \psi \phi^\dagger + \psi_a \bar{\psi}_b W_{ab}$$

$$V(\phi) = |W_a|^2 + \frac{1}{2} D_\alpha D^\alpha$$  \hspace{1cm} (3)

where $D_\alpha$ stands for the covariant derivative with respect to the gauge group and $D_\alpha$ stands for the so-called $D$-term and is given by $D_\alpha = g \phi^\dagger T_\alpha \phi$ ($g$ is the gauge coupling constant and $T_\alpha$ are the generators of the gauge group). $W_a$ and $W_{ab}$ are the first and second derivative of the superpotential $W$ with respect to the superfield with respect to the field $\Phi_a$, where the index $a$ stands for different matter fields in the model.

A very important property of supersymmetric field theories is their ultraviolet behavior which have the extremely important consequence that in the exact supersymmetric limit, the parameters of the superpotential $W(\Phi)$ do not receive any (finite or infinite) correction from Feynman diagrams involving the loops. In other words, if the value of a superpotential parameter is fixed at the classical level, it remains unchanged to all orders in perturbation theory. This is known as the non-renormalization theorem.

This observation was realized as the key to solving the Higgs mass problem of the standard model as follows: the radiative corrections to the Higgs mass in the standard model are quadratically divergent and admit the Planck scale as a natural cutoff if there is no new physics up to that level. Since the Higgs mass is directly proportional to the mass of the $W$-boson, the loop corrections would push the $W$-boson mass to the Planck scale destabilizing the standard model. On the other hand in the supersymmetric version of the standard model (to be called MSSM), in the limit of exact supersymmetry, there are no radiative corrections to any mass parameter and therefore to the Higgs boson mass which can therefore be set once and for all at the tree level. Thus if the world could be supersymmetric at all energy scales, the weak scale stability problem would be easily solved. However, since supersymmetry must be a broken symmetry, one has to ensure that the terms in the Hamiltonian that
break supersymmetry do not spoil the non-renormalization theorem in a way that infinities creep into the self mass corrections to the Higgs boson. This is precisely what happens if effective supersymmetry breaking terms are “soft” which means that they are of the following type:

1. $m_a^2 \phi^\dagger_a \phi_a$, where $\phi$ is the bosonic component of the chiral superfield $\Phi_a$;

2. $m \int d^2 \theta \theta^2 \left( AW^{(3)}(\Phi) + BW^{(2)}(\Phi) \right)$, where $W^{(3)}(\Phi)$ and $W^{(2)}(\Phi)$ are the second and third order polynomials in the superpotential.

3. $\frac{1}{2} m_\lambda \lambda \tilde{C}^{-1} \lambda$, where $\lambda$ is the gaugino field.

It can be shown that the soft breaking terms only introduce finite loop corrections to the parameters of the superpotential. Since all the soft breaking terms require couplings with positive mass dimension, the loop corrections to the Higgs mass will depend on these masses and we must keep them less than a TeV so that the weak scale remains stabilized. This has the interesting implication that superpartners of the known particles are accessible to the ongoing and proposed collider experiments. For a recent survey of the experimental situation, see Ref. 6, 7, 8.

The mass dimensions associated with the soft breaking terms depend on the particular way in which supersymmetry is broken. It is usually assumed that supersymmetry is broken in a sector that involves fields which do not have any quantum numbers under the standard model group. This is called the hidden sector. The supersymmetry breaking is then transmitted to the visible sector either via the gravitational interactions or via the gauge interactions of the standard model or via anomalous U(1) D-terms. In sec. 1.4, we discuss these different ways to break supersymmetry and their implications.

1.2 The minimal supersymmetric standard model (MSSM)

Let us now apply the discussions of the previous section to construct the supersymmetric extension of the standard model so that the goal of stabilizing the Higgs mass is indeed realized in practice. The superfields and their representation content are given in Table I.

First note that an important difference between the standard model and its supersymmetric version apart from the presence of the superpartners is the presence of a second Higgs doublet. This is required both to give masses to quarks and leptons as well as to make the model anomaly free. The gauge interaction part of the model is easily written down following the rules laid out in the previous section. In the weak eigenstate basis, weak interaction Lagrangian for the quarks and leptons is exactly the same as in the standard
Table 1: The particle content of the supersymmetric standard model. For matter and Higgs fields, we have shown the left-chiral fields only. The right-chiral fields will have a conjugate representation under the gauge group.

| Superfield                  | gauge transformation |
|-----------------------------|----------------------|
| Quarks $Q$                  | $(3, 2, \frac{1}{3})$|
| Antiquarks $u^c$            | $(3^*, 1, -\frac{4}{3})$ |
| Antiquarks $d^c$            | $(3^*, 1, \frac{2}{3})$ |
| Leptons $L$                 | $(1, 2, -1)$          |
| Antileptons $e^c$           | $(1, 1, +2)$          |
| Higgs Boson $H_u$           | $(1, 2, +1)$          |
| Higgs Boson $H_d$           | $(1, 2, -1)$          |
| Color Gauge Fields $G_a$    | $(8, 1, 0)$           |
| Weak Gauge Fields $W^\pm$, $Z$, $\gamma$ | $(1, 3 + 1, 0)$ |

As far as the weak interactions of the squarks and the sleptons are concerned, the generation mixing angles are very different from those in the corresponding fermion sector due to supersymmetry breaking. This has the phenomenological implication that the gaugino-fermion-sfermion interaction changes generation leading to potentially large flavor changing neutral current effects such as $K^0-\bar{K}^0$ mixing, $\mu \rightarrow e\gamma$ decay etc unless the sfermion masses of different generations are chosen to be very close in mass.

Let us now proceed to a discussion of the superpotential of the model. It consists of two parts:

\[ W = W_1 + W_2, \]

where

\[ W_1 = h_{ij}^L e_i^c L_j^c H_d + h_{ij}^d Q_i^c d_j^c H_d + h_{ij}^u Q_i^c u_j^c H_u + \mu H_u H_d \]

\[ W_2 = \lambda_{ijk} L_i L_j e_k^c + \lambda'_{ijk} L_i Q_j d_k^c + \lambda''_{ijk} u_i^c d_j^c d_k^c \]

$i, j, k$ being generation indices. We first note that the terms in $W_1$ conserve baryon and lepton number whereas those in $W_2$ do not. The latter are known as the $R$-parity breaking terms where $R$-parity is defined as

\[ R = (-1)^{3(B-L)+2S}, \]
where $B$ and $L$ are the baryon and lepton numbers and $S$ is the spin of the particle. It is interesting to note that the $R$-parity symmetry defined above assigns even $R$-parity to known particles of the standard model and odd $R$-parity to their superpartners. This has the important experimental implication that for theories that conserve $R$-parity, the superpartners of the particles of the standard model must always be produced in pairs and the lightest superpartner must be a stable particle. This is generally called the LSP. If the LSP turns out to be neutral, it can be thought of as the dark matter particle of the universe.

We now assume that some kind of supersymmetry breaking mechanism introduces splitting for the squarks and sleptons from the quarks and the leptons. Usually, supersymmetry breaking can be expected to introduce trilinear scalar interactions among the sfermions as follows:

$$L^{SB} = m_{3/2} [A_{e,ab} \tilde{e}^c_a \tilde{L}_b H_d + A_{d,ab} \tilde{Q}_a H_d \tilde{d}^c_b + A_{u,ab} \tilde{Q}_a H_u \tilde{u}^c_b] + B \mu m_{3/2} H_u H_d + \Sigma_{i=\text{scalars}} \mu_i^2 \phi_i^\dagger \phi_i + \Sigma_a \frac{1}{2} M_a \lambda^T C^{-1} \lambda_a$$

(8)

There will also be the corresponding terms involving the $R$-parity breaking, which we omit here for simplicity.

As already announced this model solves the Higgs mass problem in the sense that if its tree level value is chosen to be of the order of the electroweak scale, any radiative correction to it will only induce terms of order $\sim \frac{g^2 v^2}{16\pi^2} M^2_{SUSY}$. By choosing the supersymmetry breaking scale in the TeV range, we can guarantee that to all orders in perturbation theory the Higgs mass remains stable.

Constraints of supersymmetry breaking provide one prediction that can distinguish it from the nonsupersymmetric models—i.e. the mass of the lightest Higgs boson. It can be shown that the lightest higgs boson mass-square is going to be of order $\sim g^2 v^2_{u/k}$ (Ref. 7). In fact denoting the vev’s of the two Higgs doublets as $<H^0_u>=v_u$ and $<H^0_d>=v_d$, one can write:

$$m_h^2 \simeq \frac{g^2 + g'^2}{4} (v_d^2 - v_u^2)$$

(9)

Defining $v_u/v_d = tan\beta$, we can rewrite the above light Higgs mass formula as $m_h^2 = M^2_Z cos2\beta$ which implies that the tree level mass of the lightest Higgs boson is less than the $Z$ mass. Once radiative corrections are taken into account, $m_h$ increases above the $M_Z$. However, it is now well established that in a large class of supersymmetric models (which do not differ too much from the MSSM), the Higgs mass is less than 150 GeV or so.
Another very interesting property of the MSSM is that electroweak symmetry breaking can be induced by radiative corrections. As we will see below, in all the schemes for generating soft supersymmetry breaking terms via a hidden sector, one generally gets positive (mass)\(^2\)'s for all scalar fields at the scale of SUSY breaking as well as equal mass-squares. In order to study the theory at the weak scale, one must extrapolate all these parameters using the renormalization group equations. The degree of extrapolation will of course depend on the strength of the gauge and the Yukawa couplings of the various fields. In particular, the \(m^2_{H_u}\) will have a strong extrapolation proportional to \(h_t^2 \frac{\pi^2}{16\pi^2} \) since \(H_u\) couples to the top quark. Since \(h_t \simeq 1\), this can make \(m^2_{H_u}(M_Z) < 0\), leading to spontaneous breakdown of the electroweak symmetry. An approximate solution of the renormalization group equations gives

\[
m^2_{H_u}(M_Z) = m^2_{H_u}(\Lambda_{SUSY}) - \frac{3h_t^2 m_{\tilde{t}}^2}{16\pi^2} \ln \frac{\Lambda^2_{SUSY}}{M_Z^2} \tag{10}
\]

This is a very attractive feature of supersymmetric theories.

1.3 Why go beyond the MSSM?

Even though the MSSM solves two outstanding problems of the standard model, i.e. the stabilization of the Higgs mass and the breaking of the electroweak symmetry, it brings in a lot of undesirable consequences. They are:

(a) Presence of arbitrary baryon and lepton number violating couplings i.e. the \(\lambda, \lambda'\) and \(\lambda''\) couplings described above. In fact a combination of \(\lambda'\) and \(\lambda''\) couplings lead to proton decay. Present lower limits on the proton lifetime then imply that \(\lambda\lambda'' \leq 10^{-25}\) for squark masses of order of a TeV. Recall that a very attractive feature of the standard model is the automatic conservation of baryon and lepton number. The presence of R-parity breaking terms also makes it impossible to use the LSP as the Cold Dark Matter of the universe since it is not stable and will therefore decay away in the very early moments of the universe. We will see that as we proceed to discuss the various grand unified theories, keeping the R-parity violating terms under control it will provide a major constraint on model building.

(b) The different mixing matrices in the quark and squark sector leads to arbitrary amount of flavor violation manifesting in such phenomena as \(K_L - K_S\) mass difference etc. Using present experimental information and the fact that the standard model more or less accounts for the observed magnitude of these processes implies that there must be strong constraints on the mass splittings among squarks. Detailed calculations indicate that one must have
\[ \Delta \bar{m}_q^2 / m_q^2 \leq 10^{-3} \text{ or so. Again recall that this undoes another nice feature of the standard model.} \]

(c) The presence of new couplings involving the super partners allows for the existence of extra CP phases. In particular the presence of the phase in the gluino mass leads to a large electric dipole moment of the neutron unless this phase is assumed to be suppressed by two to three orders of magnitude. This is generally referred to in the literature as the SUSY CP problem. In addition, there is of course the famous strong CP problem which neither the standard model nor the MSSM provide a solution to.

In order to cure these problems as well to understand the origin of the soft SUSY breaking terms, one must seek new physics beyond the MSSM. Below, we pursue two kinds of directions for new physics: one which analyses schemes that generate soft breaking terms and a second one which leads to automatic B and L conservation as well as solves the SUSY CP problem. The second model also provides a solution to the strong CP problem without the need for an axion under certain circumstances.

### 1.4 Mechanisms for supersymmetry breaking

One of the major focus of research in supersymmetry is to understand the mechanism for supersymmetry breaking. The usual strategy employed is to assume that SUSY is broken in a hidden sector that does not involve any of the matter or forces of the standard model (or the visible sector) and this SUSY breaking is transmitted to the visible sector via some intermediary, to be called the messenger sector.

There are generally two ways to set up the hidden sector- a less ambitious one where one writes an effective Lagrangian (or superspotential) in terms of a certain set of hidden sector fields that lead to supersymmetry breaking in the ground state and another more ambitious one where the SUSY breaking arises from the dynamics of the hidden sector interactions. For our purpose we will use the simpler schemes of the first kind. As far as the messenger sector goes there are three possibilities as already referred to earlier: (i) gravity mediated \[ (ii) \text{ gauge mediated} \] and (iii) anomalous U(1) mediated. Below we give examples of each class.

(i) **Gravity mediated SUSY breaking**

The scenario that uses gravity to transmit the supersymmetry breaking is one of the earliest hidden sector scenarios for SUSY breaking and forms much of the basis for the discussion in current supersymmetry phenomenology. In order to discuss these models one needs to know the supersgravity couplings
to matter. This is given in the classic paper of Cremmer et al.\textsuperscript{15}. An essential feature of supergravity coupling is the generalized kinetic energy term in gravity coupled theories called the Kahler potential, $K$. We will denote this by $G$ and it is a hermitean operator which is a function of the matter fields in the theory and their complex conjugates. The effect of supergravity coupling in the matter and the gauge sector of the theory is given in terms of $G$ and its derivatives as follows:

$$L(z) = G_{zz^*} |\partial_\mu z|^2 + e^{-G} [G_z G_{z^*} G_{-z^*}^{-1} + 3]$$

where $z$ is the bosonic component of a typical chiral field (e.g. we would have $z \equiv \tilde{q}, \tilde{t}$ etc) and $G = 3ln(\sqrt{K}) - ln|W(z)|^2$. A superscript implies derivative with respect to that field. The simplest choice for the Kahler potential $K$ is $K = -3e^{-\frac{\mu^2}{2M_{Pl}}}$ that normalizes the kinetic energy term properly. Using this, one can the effective potential for supergravity coupled theories to be:

$$V(z, z^*) = e^{-\frac{\mu^2}{2M_{Pl}}} [\frac{W_z}{M_{Pl}} |W|^2 - \frac{3}{M_{Pl}^2} |W|^2] + D - terms$$

The gravitino mass is given internms of the Kahler potential as:

$$m_{3/2} = M_{Pl} e^{-G/2}$$

A popular scenario suggested by Polonyi is based upon the following hidden sector consisting of a gauge singlet field, denoted by $z$ and the superpotential $W_H$ given by:

$$W_H = \mu^2 (z + \beta)$$

where $\mu$ and $\beta$ are mass parameters to be fixed by various physical considerations. It is clear that this superpotential leads to an F-term that is always non-vanishing and therefore breaks supersymmetry. Requiring the cosmological constant to vanish fixes $\beta = (2 - \sqrt{3})M_{Pl}$. Given this potential and the choice of the Kahler potential as discussed earlier, supergravity calculus predicts a universal soft breaking parameters $m$ given by $m_0 \sim \mu^2 / M_{Pl}$. Requiring $m_0$ to be in the TeV range implies that $\mu \sim 10^{11}$ GeV. The complete potential to zeroth order in $M_{Pl}^{-1}$ in this model is given by:

$$V(\phi_a) = [\Sigma_a |\partial W / \partial \phi_a|^2 + V_D] + [m_0^2 \Sigma_a \phi_a^* \phi_a + (AW^{(3)} + BW^{(2)} + h.c.)$$

11
where $W^{(3,2)}$ denote the dimension three and two terms in the superpotential respectively. The values of the parameters $A$ and $B$ at $M_{Pl}$ are related to each other in this example as $B = A - 1$. The gaugino masses in these models arise out of a separate term in the Lagrangian depending on a new function of the hidden sector singlet fields, $z$:

$$
\int d^4xd^2\theta f(z)W_{\lambda,\alpha}^{\prime}W_{\lambda,\alpha}
$$

If we choose $f(z) = \frac{z}{M_{Pl}}$, then gaugino masses come out to be order $m_{3/2} \sim \frac{1}{M_{Pl}}$ which is also of order $m_0$, i.e. the electroweak scale. Furthermore, in order to avoid undesirable color and electric charge breaking by the SUSY models, one must require that $m_0^2 \geq 0$.

It is important to point out that the superHiggs mechanism operates at the Planck scale. Therefore all parameters derived at the tree level of this model need to be extrapolated to the electroweak scale. So after the soft-breaking Lagrangian is extrapolated to the weak scale, it will look like:

$$
\mathcal{L}^{SB} = m_a^2 \phi_a^* \phi_a + m \Sigma_{i,j,k} A_{ijk} \phi_i \phi_j \phi_k + \Sigma_{i,j} B_{ij} \phi_i \phi_j
$$

These extrapolations depend among other things on the Yukawa couplings of the model. As a result of this the universality of the various SUSY breaking terms is no more apparent at the electroweak scale. Moreover, since the top Yukawa coupling is now known to be of order one, its effect turns the mass-squared of the $H_u$ negative at the electroweak scale even starting from a positive value at the Planck scale\[14\]. This provides a natural mechanism for the breaking of electroweak symmetry adding to the attractiveness of supersymmetric models. In the lowest order approximation, one gets,

$$
m_{H_u}^2(M_Z) \sim m_{H_u}^2(M_{Pl}) - \frac{3h_t^2}{8\pi^2} \ln\left(\frac{M_{Pl}}{M_Z}\right)(m_{H_u}^2 + m_q^2 + m_u^2)|_{\mu = M_{Pl}}
$$

Before leaving this section it is worth pointing out that despite the simplicity and the attractiveness of this mechanism for SUSY breaking, there are several serious problems that arise in the phenomenological study of the model that has led to the exploration of other alternatives. For instance, the observed constraints on the flavor changing neutral currents\[13\] require that the squarks of the first and the second generation must be nearly degenerate, which is satisfied if one assumes the universality of the spartner masses at the Planck scale. However this universality depends on the choice of the Kahler potential which is adhoc.
Before we move on to the discussion of the alternative scenarios for hidden sector, we point out an attractive choice for the Kahler potential which leads naturally to the vanishing of the cosmological constant unlike in the Polonyi case where we had to dial the large cosmological constant to zero. The choice is \( G = 3 \ln(S + S^\dagger) \), which as can easily be checked from the Eq. 11 to lead to \( V = 0 \). This is known as the no scale model\(^{17}\) and usually emerges in the case of string models\(^ {18}\). A complete and successful implementation of this idea with the gravitino mass generated in a natural way in higher orders is still not available.

(ii) Gauge mediated SUSY breaking\(^ 4\)

This mechanism for the SUSY breaking has recently been quite popular in the literature and involves different hidden as well as messenger sectors. In particular, it proposes to use the known gauge forces as the messengers of supersymmetry breaking. As an example, consider a unified hidden messenger sector toy model of the following kind, consisting of the fields \( \Phi_1, \Phi_2 \) and \( \bar{\Phi}_1, \bar{\Phi}_2 \) which have the standard model gauge quantum numbers and a singlet field \( S \) and with the following superpotential:

\[
W = \lambda S(M_0^2 - \Phi_1 \Phi_1) + M_1 (\Phi_1 \Phi_2 + \Phi_1 \bar{\Phi}_2) + M_2 \Phi_1 \bar{\Phi}_1
\]  

(19)

The F-terms of this model are given by:

\[
F_S = \lambda (M_0^2 - \Phi_1 \Phi_1) \\
F_{\Phi_2} = M_1 \Phi_1; \quad F_{\bar{\Phi}_2} = M_1 \Phi_1 \\
F_{\Phi_1} = M_2 \bar{\Phi}_1 + M_1 \bar{\Phi}_2 - \lambda S \Phi_1
\]  

(20)

It is easy to see from the above equation that for \( M_1 \gg M_0, M_2 \), the minimum of the potential corresponds to all \( \Phi \)'s having zero vev and \( F_S = \lambda M_0^2 \), thus breaking supersymmetry. The same superpotential responsible for SUSY breaking also transmits the SUSY breaking information to the visible sector. While the spirit of this model\(^ 4\) is similar to the original papers on the subject this unified construction is different and has its characteristic predictions.

The SUSY breaking to the visible sector is transmitted via one and two loop diagrams. The gaugino masses arise from the one loop diagram where a gaugino decomposes into the SUSY partners \( \phi_1 \) and \( \phi \) and the loop is completed as \( \phi_1 \) and \( \phi_1 \) mix thru \( F_S \) susy breaking term and the fermionic partners mix via the mass term \( M_2 \). The squark and slepton masses arise from the two loop diagram where the squark-squark gauge boson -gauge boson coupling begins the first loop and one of the gauge bosons couples to the two \( \phi_1 \)'s and another
to the two $\bar{\Phi}_1$'s which in turn mix via the F-terms for S to complete the two loop diagram. This is only one typical diagram and there are many more which contribute in the same order (see Martin, Ref. 20). It is then easy to see that their magnitudes are given by:

$$m_\lambda \simeq \frac{\alpha}{4\pi} \frac{<F_S>}{M_2}$$

The first point to notice is that the gaugino and squark masses are roughly of the same order and requiring the squark masses to be around 100 GeV, we get for $F_S/M_2 \simeq 100$ TeV. Of course, $<F_S>$ and $M_2$ need not be of same order in which case the numerics will be different. Another important point to note is that by choosing the quantum numbers of the messengers $\Phi_i$ appropriately, one can have widely differing spectra for the superpartners.

A distinguishing feature of this approach is that due to low scale for SUSY breaking, the gravitino mass is always in the milli-eV to kilo-eV range and is therefore is always the LSP. Thus these models cannot lead to a supersymmetric CDM.

The attractive property of these models is that they lead naturally to near degeneracy of the squark and sleptons thus alleviating the FCNC problem of the MSSM and have therefore been the focus of intense scrutiny during the past year.

These class of models however suffer from the fact that the messenger sector is too adhoc.

(iii) Anomalous U(1) mediated supersymmetry breaking

These class of models owe their origin to the string models, which after compactification can often leave anomalous U(1) gauge groups\[21\]. Since the original string model is anomaly free, the anomaly cancellation must take place via the Green-Schwarz mechanism as follows. Consider a U(1) gauge theory with a single chiral fermion that carries a U(1) quantum number. This theory has an anomaly. Therefore, under a gauge transformation, the low energy Lagrangian is not invariant and changes as:

$$L \rightarrow L + \frac{\alpha}{4\pi} F \tilde{F}$$

where $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ and $\tilde{F}$ is the dual of $F_{\mu\nu}$. The last term is the anomaly term. To restore gauge invariance, we can add to the Lagrangian the

$$m_\lambda \simeq \frac{\alpha}{4\pi} \frac{<F_S>}{M_2} \tag{21}$$

$$m_\tilde{q}^2 \simeq \left( \frac{\alpha}{4\pi} \right)^2 \left( \frac{<F_S>}{M_2} \right)^2$$

where $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ and $\tilde{F}$ is the dual of $F_{\mu\nu}$. The last term is the anomaly term. To restore gauge invariance, we can add to the Lagrangian the
Green-Schwarz term and rewrite the effective Lagrangian as

\[ L' = L + \frac{a}{M} F \tilde{F} \]  

(23)

where under the gauge transformation \( a \rightarrow a - M\alpha/4\pi \). In order to obtain the supersymmetric version of the Green-Schwarz term, we have to add a dilaton term to the axion \( a \) to make a complex chiral superfield. Let us denote the dilaton field by \( \phi \) and the complex chiral field containing it as \( S = \phi + ia \). The gauge invariant action containing the \( S \) and the gauge supersfield \( V \) has terms of the following form:

\[
A = \int d^4\theta \ln(S + S^\dagger - V) + \int d^2\theta SW^\alpha W_\alpha + \text{matter field parts}
\]

(24)

It is clear that in order to get a gauge field Lagrangian out of this, the dilaton \( S \) must have a vev with the identification that \( \langle S \rangle = g^{-2} \) and it is a fundamental unanswered question in superstring theory as to how this vev arises. If we assume that this vev has been generated, then, one can see that the first term in the Lagrangian when expanded around the dilaton vev, leads to a term \( \frac{1}{224} \int d^4\theta V \), which is nothing but a linear Fayet-Illiopoulos D-term. Combining this with other matter field terms with non-zero U(1) charge, one can then write the D-term of the Lagrangian. As an example that can lead to realistic model building, we take two fields with equal and opposite U(1) charges \( \pm 1 \) in addition to the squark and slepton fields. The D-term can then be written as:

\[
V_D = \frac{g^2}{2}(n_Q^2|\tilde{Q}|^2 + n_L^2|\tilde{L}|^2 + |\phi_+|^2 - |\phi_-|^2 + \zeta)^2
\]

(25)

This term when minimized does not break supersymmetry. However, if we add the superpotential a term of the form \( W_\phi = m\phi_+\phi_- \), then there is another term in low energy effective potential that leads to the combined potential as:

\[
V = V_D + m^2(|\phi_+|^2 + |\phi_-|^2)
\]

(26)

The minimum of this potential corresponds to:

\[
\langle \phi_+ \rangle = 0; \langle \phi_- \rangle = (\zeta - \frac{m_\phi^2}{g^2})^{1/2} \simeq \epsilon M_{Pl} : F_\phi = mM_{Pl}\epsilon
\]

(27)

where we have assumed that \( \zeta = \epsilon^2 M_{Pl}^2 \). This then leads to nonzero squark masses \( m_\tilde{Q} \simeq n_Q^2 m^2 \). Thus supersymmetry is broken and superpartners pick up mass. In the simplest model it turns out that the gaugino masses may be
too low and one must seek ways around this. However, the A and B-terms are also likely to be small in this model and that may provide certain advantages. On the whole, this approach has great potential for model building and has not been thoroughly exploited, for instance, it can be used to solve the FCNC problems, SUSY CP problem, to study the fermion mass hierarchies etc. It is beyond the scope of this review to enter into those areas. One can expect to see activity in this area blossom.

1.5 Supersymmetric Left-Right model

One of the attractive features of the supersymmetric models is its ability to provide a candidate for the cold dark matter of the universe. This however relies on the theory obeying $R$-parity conservation (with $R \equiv (-1)^{3(B-L)+2S}$). It is easy to check that particles of the standard model are even under $R$ whereas their superpartners are odd. The lightest superpartner is then absolutely stable and can become the dark matter of the universe. In the MSSM, $R$-parity symmetry is not automatic and is achieved by imposing global baryon and lepton number conservation on the theory as additional requirements. First of all, this takes us one step back from the non-supersymmetric standard model where the conservation $B$ and $L$ arise automatically from the gauge symmetry and the field content of the model. Secondly, there is a prevalent lore supported by some calculations that in the presence of nonperturbative gravitational effects such as black holes or worm holes, any externally imposed global symmetry must be violated by Planck suppressed operators. In this case, the $R$-parity violating effects again become strong enough to cause rapid decay of the lightest $R$-odd neutralino so that there is no dark matter particle in the minimal supersymmetric standard model. It is therefore desirable to seek supersymmetric theories where, like the standard model, $R$-parity conservation (hence Baryon and Lepton number conservation) becomes automatic i.e. guaranteed by the field content and gauge symmetry. It was realized in mid-80's that such is the case in the supersymmetric version of the left-right model that implements the see-saw mechanism for neutrino masses. We briefly discuss this model in the section.

The gauge group for this model is $SU(2)_L \times SU(2)_R \times U(1)_{B-L} \times SU(3)_c$. The chiral superfields denoting left-handed and right-handed quark superfields are denoted by $Q \equiv (u,d)$ and $Q^c \equiv (d^c,-u^c)$ respectively and similarly the lepton superfields are given by $L \equiv (\nu,e)$ and $L^c \equiv (e^c,-\nu^c)$. The $Q$ and $L$ transform as left-handed doublets with the obvious values for the $B-L$ and the $Q^c$ and $L^c$ transform as the right-handed doublets with opposite $B-L$ values. The symmetry breaking is achieved by the following set of Higgs su-
perfields: $\phi_a(2, 2, 0, 1) \ (a = 1, 2)$; $\Delta(3, 1, +2, 1)$; $\bar{\Delta}(3, 1, -2, 1)$; $\Delta^c(1, 3, -2, 1)$ and $\bar{\Delta}^c(1, 3, +2, 1)$. There are alternative Higgs multiplets that can be employed to break the right handed $SU(2)$; however, this way of breaking the $SU(2)_R \times U(1)_{B-L}$ symmetry automatically leads to the see-saw mechanism for small neutrino masses\[25\] as mentioned.

The superpotential for this theory has only a very limited number of terms and is given by (we have suppressed the generation index):

$$W = Y^{(i)}_q Q^T \tau_2 \Phi^c \tau_2 Q^c + Y^{(i)}_l L^T \tau_2 \Phi^c \tau_2 L^c$$
$$+ i(f L^T \tau_2 \Delta L + f_c L^T \tau_2 \bar{\Delta} L^c)$$
$$+ \mu \Delta \text{Tr}(\Delta \bar{\Delta}) + \mu_{\Delta^c} \text{Tr}(\Delta^c \bar{\Delta}^c) + \mu_{ij} \text{Tr}(\tau_2 \Phi_i^T \tau_2 \Phi_j)$$
$$+ W_{NR}$$

where $W_{NR}$ denotes non-renormalizable terms arising from higher scale physics such as grand unified theories or Planck scale effects. At this stage all couplings $Y^{(i)}_q, l$, $\mu_{ij}$, $\mu_{\Delta}$, $\mu_{\Delta^c}$, $f, f_c$ are complex with $\mu_{ij}$, $f$ and $f_c$ being symmetric matrices.

The part of the supersymmetric action that arises from this is given by

$$S_W = \int d^4x \int d^2\theta W + \int d^4x \int d^2\bar{\theta} W^\dagger.$$  \hspace{1cm} (29)

It is clear from the above equation that this theory has no baryon or lepton number violating terms. Since all other terms in the theory automatically conserve B and L, R-parity symmetry $(-1)^{3(B-L)+2S}$ is automatically conserved in the SUSYLR model. As a result, it allows for a dark matter particle provided the vacuum state of the theory respects R-parity. The desired vacuum state of the theory which breaks parity and preserves R-parity corresponds to $<\Delta^c> \equiv v_R \neq 0$; $<\bar{\Delta}^c> \neq 0$ and $<\bar{\nu}^c> = 0$. This reduces the gauge symmetry to that of the standard model which is then broken via the vev’s of the $\phi$ fields. These two together via the see-saw mechanism\[23\] lead to a formula for neutrino masses of the form $m_\nu \simeq \frac{m^2}{f^{\phi}}$. Thus we see that the suppression of the $V + A$ currents at low energies and the smallness of the neutrino masses are intimately connected.

It turns out that left-right symmetry imposes rather strong constraints on the ground state of this model. It was pointed out in 1993\[26\] that if we take the minimal version of this model, the ground state leaves the gauge symmetry unbroken. To break gauge symmetry one must include singlets in the theory. However, in this case, the ground state breaks electric charge unless R-parity
is spontaneously broken. Furthermore, R-parity can be spontaneously broken only if $M_{W_R} \leq \text{few TeV's}$. Thus the conclusion is that the renormalizable version of the SUSYLR model with only singlets, $B - L = \pm 2$ triplets and bidoublets can have a consistent electric charge conserving vacuum only if the $W_R$ mass is in the TeV range and R-parity is spontaneously broken. This conclusion can however be avoided either by making some very minimal extensions of the model such as adding superfields $\delta(3, 1, 0, 1) + \bar{\delta}(1, 3, 0, 1)$ or by adding nonrenormalizable terms to the theory. Such extra fields often emerge if the model is embedded into a grand unified theory or is a consequence of an underlying composite model.

In order to get a R-parity conserving vacuum (as would be needed if we want the LSP to play the role of the cold dark matter) without introducing the extra fields mentioned earlier, one must add the non-renormalizable terms. In this case, the doubly charged Higgs bosons and Higgsinos become very light unless the $W_R$ scale is above $10^{10}$ GeV or so (and Aulakh et al. Ref.28). This implies that the neutrino masses must be in the eV range, as would be required if they have to play the role of the hot dark matter. Thus an interesting connection between the cold and hot dark matter emerges in this model in a natural manner.

This model solves two other problems of the MSSM: (i) one is the SUSY CP problem and (ii) the other is the strong CP problem when the $W_R$ scale is low. To see how this happens, let us define the transformation of the fields under left-right symmetry as follows and observe the resulting constraints on the parameters of the model.

\[
\begin{align*}
Q &\leftrightarrow Q^c \\
L &\leftrightarrow L^c \\
\Phi_i &\leftrightarrow \Phi_i^\dagger \\
\Delta &\leftrightarrow \Delta^c \\
\bar{\Delta} &\leftrightarrow \bar{\Delta}^c \\
\theta &\leftrightarrow \bar{\theta} \\
\tilde{W}_{SU(2)_L} &\leftrightarrow \tilde{W}^*_{SU(2)_R} \\
\tilde{W}_{B-L,SU(3)_C} &\leftrightarrow \tilde{W}^*_{B-L,SU(3)_C}
\end{align*}
\]

Note that this corresponds to the usual definition $Q_L \leftrightarrow Q_R$, etc. To study its implications on the parameters of the theory, let us write down the most general soft supersymmetry terms allowed by the symmetry of the model (which make the theory realistic).
\[ \mathcal{L}_{\text{soft}} = \int d^4\theta \sum_i m_i^2 \phi_i^\dagger \phi_i + \int d^2\theta \theta^2 \sum_i A_i W_i + \int d^2\bar{\theta} \bar{\theta}^2 \sum_i A_i^\dagger W_i^\dagger \\
+ \int d^2\theta \theta^2 \sum_p m_{\lambda_p} \bar{W}_p \bar{W}_p + \int d^2\bar{\theta} \bar{\theta}^2 \sum_p m_{\lambda_p}^* \bar{W}_p^* \bar{W}_p^* . \tag{31} \]

In Eq. 31, \( \bar{W}_p \) denotes the gauge-covariant chiral superfield that contains the \( F_{\mu\nu} \)-type terms with the subscript going over the gauge groups of the theory, including SU(3)\(_c\). \( W_i \) denotes the various terms in the superpotential, with all superfields replaced by their scalar components and with coupling matrices which are not identical to those in \( W \). Eq. 31 gives the most general set of soft breaking terms for this model.

With the above definition of L-R symmetry, it is easy to check that

\[
Y_{q,l}^{(i)} = Y_{q,l}^{(i)\dagger} \\
\mu_{ij} = \mu_{ij}^* \\
\mu_{\Delta} = \mu_{\Delta}^* \\
f = f_c^* \\
m_{\lambda SU(2)_L} = m_{\lambda SU(2)_R} \\
m_{\lambda_{B-L,SU(3)_C}} = m_{\lambda_{B-L,SU(3)_C}}^* \\
A_i = A_i^\dagger , \tag{32} \]

Note that the phase of the gluino mass term is zero due to the constraint of parity symmetry. As a result the one loop contribution to the electric dipole moment of neutron from this source vanishes in the lowest order. The higher order loop contributions that emerge after left-right symmetry breaking can be shown to be small, thus solving the SUSYCP problem. Further more, since the constraints of left-right symmetry imply that the quark Yukawa matrices are hermitean, if the vaccum expectation values of the \( \langle \phi \rangle \) fields are real, then the \( \Theta \) parameter of QCD vanishes naturally at the tree level. This then provides a solution to the strong CP problem. It however turns out that to keep the one loop finite contributions to the \( \Theta \) less than \( 10^{-9} \), the \( W_R \) scale must be in the TeV range. Such models generally predict the electric dipole moment of neutron of order \( 10^{-26} \) ecm which can be probed in the next round of neutron dipole moment searches.

The phenomenology of this model has been extensively studied in recent papers and we do not go into them here. A particularly interesting phenomeno-
logical prediction of the model is the existence of the light doubly charged Higgs bosons and the corresponding Higgsinos.

2 Unification of Couplings

Soon after the discovery of the standard model, it became clear that embedding the model into higher local symmetries may lead to two very distinct conceptual advantages: (i) they may provide quark lepton unification providing a unified understanding of the apriori separate interactions of the two different types of matter and (ii) they can lead to description of different forces in terms of a single gauge coupling constant. How actually the unification of gauge couplings occurs was discussed in a seminal paper by Georgi, Quinn and Weinberg. They used the already known fact that the coupling parameters in a theory depend on the mass scale and showed that the gauge couplings of the standard model can indeed unify at a very high scale of order $10^{15}$ GeV or so. Although this scale might appear too far removed from the energy scales of interest in particle physics then, it was actually a blessing in disguise since in GUT theories, obliteration of the quark-lepton distinction manifests itself in the form of baryon instability such as proton decay and the rate of proton decay is inversely proportional to the 4th power of the grand unification scale and only for scales near $10^{15}$ GeV or so, already known lower limits on proton life times could be reconciled with theory. This provided a new impetus for new experimental searches for proton decay. The minimal grand unification model based on the SU(5) group suggested by Georgi and Glashow made very precise prediction for the proton lifetime of $\tau_p$ between $1.6 \times 10^{30}$ yrs. to $2.5 \times 10^{28}$ yrs. Attempts to observe proton decay at this level failed ruling out the simple minimal non-supersymmetric SU(5) model. In fact the situation was worse since the minimal non-supersymmetric SU(5) also predicted a value for $\sin^2 \theta_W$ which is much lower than the experimentally observed one.

A revival of interest in the idea of grand unification occurred after the ideas of supersymmetry became part of phenomenology of particle physics in the early 80’s. Two points were realized that led to this. First is that a theoretical understanding of the large hierarchy between the weak scale and the GUT scale was possible only within the framework of supersymmetry as discussed in the first chapter. Secondly, on a more phenomenological level, measured values of $\sin^2 \theta_W$ from the accelerators coupled with the observed values for $\alpha_{\text{strong}}$ and $\alpha_{\text{em}}$ could be reconciled with the unification of gauge couplings only if the superpartners were included in the evolution of the gauge couplings and the supersymmetry breaking scale was assumed to be near the weak scale, which was independently motivated anyway.
It should be however made clear that supersymmetry is not the only well motivated beyond standard model physics that leads to coupling constant unification consistent with the measured value of $\sin^2 \theta_W$. If the neutrinos have masses in the micro-milli-eV range, then the see-saw mechanism given by the formula

$$m_{\nu_i} \approx \frac{m_{\nu_i}^2}{M_{B-L}}$$

implies that the $M_{B-L}$ scale is around $10^{11}$ GeV or so. It was shown in the early 80's that coupling constant unification can take place without any need for supersymmetry if it is assumed that above the $M_{B-L}$ the gauge symmetry becomes $SU(2)_L \times SU(2)_R \times U(1)_{B-L} \times SU(3)_c$ or $SU(2)_L \times SU(2)_R \times SU(4)_c$. Since the subject of these lectures is supersymmetric grand unification, I will not discuss these models here. Let us now proceed to discuss the unification of gauge couplings in supersymmetric models.

2.1 Unification of Gauge Couplings (UGC)

Key ingredients in this discussion are the renormalization group equations (RGE) for the gauge coupling parameters. Suppose we want to evolve a coupling parameter between the scales $M_1$ and $M_2$ (i.e. $M_1 \leq \mu \leq M_2$) corresponding to the two scales of physics. Then the RGE’s depend on the gauge symmetry and the field content at $\mu = M_1$. The one loop evolution equations for the gauge couplings (define $\alpha_i \equiv g_i^2 / 4\pi$) are:

$$\frac{d\alpha_i}{dt} = \frac{1}{2\pi} b_i \alpha_i^2$$

where $t = \ln \mu$. The coefficient $b_i$ receives contributions from the gauge part and the matter including Higgs field part. In general,

$$b_i = -3C_2(G) + T(R_1)d(R_2)$$

where $C_2(R) = \Sigma a_a R_a R_a$ and $T(R)\delta^{ab} = Tr(R_a R_b)$. $R_a$ are the generators of the gauge group under consideration. The following group theoretical relations are helpful in making actual calculations:

$$C_2(R)d(R) = T(R)r$$

where $d(R)$ is the dimension of the irreducible representation and $r$ is the rank of the group (the number of diagonal generators).
An important point to note is that since at the GUT scale one imagines that the symmetry group merges into one GUT group, all the low energy generators must be normalized the same way. What this means is that if \( \Theta_a \) are the generators of the groups at low energy, one must satisfy the condition that \( \text{Tr}(\Theta_a \Theta_b) = 2 \delta_{ab} \). If we sum over the fermions of the same generation, we easily see that this condition is satisfied for the \( SU(2)_L \) and the \( SU(3)_c \) groups.

On the other hand, for the hypercharge generator, one must write \( \Theta_Y = \sqrt{\frac{3}{2}} Y \) to satisfy the correct normalization condition. This must therefore be used in evaluating the \( b_1 \).

One can calculate the \( b_i \) for the MSSM and they are \( b_3 = -3 \), \( b_2 = +1 \) and \( b_1 = +33/5 \) where the subscript \( i \) denotes the \( SU(i) \) group (for \( i > 1 \)) and we have assumed three generations of fermions. The gauge coupling evolution equations can then be written as:

\[
\begin{align*}
2\pi \frac{d\alpha_1^{-1}}{dt} &= -\frac{33}{5} \\
2\pi \frac{d\alpha_2^{-1}}{dt} &= -1 \\
2\pi \frac{d\alpha_3^{-1}}{dt} &= 3
\end{align*}
\]

The solutions to these equations are:

\[
\begin{align*}
\alpha_1^{-1}(M_Z) &= \alpha_U^{-1} + \frac{33}{10\pi} \ln \frac{M_U}{M_Z} \\
\alpha_2^{-1}(M_Z) &= \alpha_U^{-1} + \frac{1}{2\pi} \ln \frac{M_U}{M_Z} \\
\alpha_3^{-1}(M_Z) &= \alpha_U^{-1} - \frac{3}{2\pi} \ln \frac{M_U}{M_Z}
\end{align*}
\]

If these three equations which have only two free parameters hold then coupling constant unification occurs. These equations lead to the consistency equation:

\[
\Delta \alpha \equiv 5\alpha_1^{-1}(M_Z) - 12\alpha_2^{-1}(M_Z) + 7\alpha_3^{-1}(M_Z) = 0
\]

Using the values of the three gauge coupling parameters measured at the \( M_Z \) scale, i.e.

\[
\begin{align*}
\alpha_1^{-1}(M_Z) &= 58.97 \pm .05 \\
\alpha_2^{-1}(M_Z) &= 29.61 \pm .05 \\
\alpha_3^{-1}(M_Z) &= 8.47 \pm .22
\end{align*}
\]
(where we have taken for the strong coupling constant the global average given in Ref. 40), we find that $\Delta \alpha = -1 \pm 2$. Thus we see that grand unification of couplings occurs in the one loop approximation. Again subtracting any two of the above evolution equations, we find the unification scale to be $M_U \sim 10^{16}$ GeV and $\alpha_{U}^{-1} \approx 24$. There are of course two loop effects, corrections arising from the fact that all particle masses may not be degenerate and turn on as a Theta function in the evolution equations etc. Another point worth noting is that while the value of $\alpha_{1,2}(M_Z)$ are quite accurately known, the same is not the case for the strong coupling constant and in fact detailed two loop calculations and the MSSM threshold corrections reveal that if the effective MSSM scale ($T_{SUSY}$) is less than $M_Z$, one needs $\alpha_{s}(M_Z) > .121$ to achieve unification. Thus indications of a smaller value for the QCD coupling would indicate more subtle aspects to coupling constant unification such as perhaps intermediate scales or new particles etc.

To better appreciate the degree of unification in supersymmetric models, let us compare this with the evolution of couplings in the standard model. The values of $b_i$ for this case are $b_1 = 41/10$, $b_2 = -19/6$ and $b_3 = -7$. The gauge coupling unification in this case would require that

$$\Delta \alpha_{sm} = \frac{6}{23} \alpha_{3}^{-1}(M_Z) - \frac{309}{2507} \alpha_{2}^{-1}(M_Z) + \frac{15}{109} \alpha_{1}^{-1}(M_Z) = 0 \quad (42)$$

Using experimental inputs as before, it is easy to check that $\Delta \alpha_{sm} = 6.5 \pm 2$, which is away from zero by many sigma’s.

2.2 Gauge coupling unification with intermediate scales before grand unification

An important aspect of grand unification is the possibility that there are intermediate symmetries before the grand unification symmetry is realized. For instance a very well motivated example is the presence of the gauge group $SU(2)_L \times SU(2)_R \times U(1)_{B-L} \times SU(3)_C$ before the gauge symmetry enlarges to the SO(10) group. So it is important to discuss how the evolution equation equations are modified in such a situation.

Suppose that at the scale $M_I$, the gauge symmetry enlarges. To take this into account, we need to follow the following steps:

(i) If the smaller group $G_1$ gets embedded into a single bigger group $G_2$ at $M_I$, then at the one loop level, we simply impose the matching condition:

$$g_1(M_I) = g_2(M_I) \quad (43)$$

(ii) On the other hand if the generators of the low scale symmetry arise as
linear combinations of the generators of different high scale groups as follows:

$$\lambda_b = \Sigma p_b \theta_b$$  \hspace{1cm} (44)

then the coupling matching condition is:

$$\frac{1}{g_1^2(M)} = \Sigma p_b \frac{b^2}{g_b^2(M)}$$  \hspace{1cm} (45)

One can prove this as follows: for simplicity let us consider only the case where \( G_2 = \Pi_b U(1)_b \) which at \( M_I \) breaks down to a single \( U(1) \). Let this breaking occur via the vev of a single Higgs field \( \phi \) with charges \( (q_1, q_2, ...) \) under \( U(1) \). The unbroken generator is given by:

$$Q = \Sigma p_a Q_a$$  \hspace{1cm} (46)

with \( \Sigma c p_c q_c = 0 \). The gauge field mass matrix after Higgs mechanism can be written as

$$M_{ab}^2 = g_a g_b q_a q_b \langle \phi \rangle^2$$  \hspace{1cm} (47)

This mass matrix has the following massless eigenstate which can be identified with the unbroken \( U(1) \) gauge field:

$$A_{\mu,b} = \frac{1}{\Sigma p_b g_b} \frac{p_b}{g_b} A_{\mu,b} \equiv N \frac{p_b}{g_b} A_{\mu,b}$$  \hspace{1cm} (48)

To find the effective gauge coupling, we write

$$L \sim \Sigma g_b Q_b A_{\mu,b}$$  \hspace{1cm} (49)

$$= \Sigma g_b (p_a Q + ...) N \frac{p_b}{g_b} A_{\mu,b} + ...$$

Collecting the coefficient of \( A_{\mu} \) and using the normalization condition \( \Sigma p_b^2 = 1 \), we get the result we wanted to prove (i.e. Eq.).

Let us apply this to the situation where \( SU(2)_R \times U(1)_{B-L} \) is broken down to \( U(1)_Y \). In that case:

$$Y = I_{3,R} + \frac{B - L}{2}$$  \hspace{1cm} (50)

The normalized generators are \( I_Y = \left( \frac{1}{2} \right)^{1/2} \frac{Y}{2} \) and \( I_{B-L} = \left( \frac{1}{2} \right)^{1/2} \frac{B-L}{2} \). Using them, one finds that

$$I_Y = \sqrt{3} I_{3R} + \sqrt{2} I_{B-L}$$  \hspace{1cm} (51)
This implies that the matching of coupling constant at the scale where the left-right symmetry begins to manifest itself is given by:

$$\alpha_Y^{-1} = \frac{3}{5} \alpha_{2R}^{-1} + \frac{2}{5} \alpha_{B-L}^{-1}$$  \hspace{1cm} (52)

**Application to SO(10) GUT and possibility of low W_R scale**

Let us apply this to the SO(10) model to see under what conditions a low W_R mass can be consistent with coupling constant unification. Let us first derive the evolution equations for the couplings in SO(10) model with an intermediate W_R scale. For the \(\alpha_2\) and \(\alpha_3\), the evolution equations are straightforward and given by:

$$\alpha_i^{-1}(M_Z) = \alpha_i^{-1}(M_R) - \frac{b_i}{2\pi} \ln \frac{M_R}{M_Z} - \frac{b'_i}{2\pi} \ln \frac{M_U}{M_R}$$  \hspace{1cm} (53)

where \(i = 2, 3\) and \(b'_i\) receives contributions from all particles at and below the scale \(M_R\). We assume that there are no other particles between \(M_R\) and \(M_U\) other than those included in \(b_i\). Turning to \(\alpha_1\), we have to use the matching formula derived above. Using that, we find that

$$\alpha_1^{-1}(M_Z) = \alpha_1^{-1}(M_R) - \frac{b_1}{2\pi} \ln \frac{M_R}{M_Z}$$  \hspace{1cm} (54)

Using the matching formula derived above, and evolving the \(\alpha_{2R,B-L}\) between \(M_R\) and \(M_U\), we find that

$$\alpha_1^{-1}(M_Z) = \alpha_1^{-1}(M_R) - \frac{b_1}{2\pi} \ln \frac{M_R}{M_Z} - \left(\frac{3}{5} b_{2R}' - \frac{2}{5} b_{B-L}'\right) \ln \frac{M_U}{M_R}$$  \hspace{1cm} (55)

In the discussion that follows let us denote \(3/5b_{2R}' + 2/5b_{B-L}' = b_1'\). We then see that a sufficient condition for the intermediate scale to exist is that we must have

$$\Delta \alpha_{SUSY} = 5b_1' - 12b_{2L}' + 7b_3' = 0$$  \hspace{1cm} (56)

In fact if this condition is satisfied, at the one loop level, one can even have a W_R mass in the TeV range and still have coupling constant unification. As an example of such a theory, consider the following spectrum of particles above \(M_R\): a color octet, a pair of \(SU(2)_R\) triplets with \(B - L = \pm 2\), two bidoublets \(\phi(2, 2, 0)\) and a left-handed triplet. The corresponding b-coefficients above \(M_R\) are given by:

$$b_3' = 0; b_{2L}' = 4; b_{2R}' = 6 \text{ and } b_{B-L}' = 15$$  \hspace{1cm} (57)

This theory satisfies the condition that \(\Delta \alpha_{SUSY} = 0\) and can support a low W_R theory.
2.3 Yukawa unification

Another extension of the idea of gauge coupling unification is to demand the unification of Yukawa coupling parameters and study its implications and predictions. This however is a much more model dependent conjecture than the UGC\[^4\]. One may of course demand partial Yukawa unification instead of a complete one between all three generations. As we will see in the next chapter, most grand unification models tend to imply partial Yukawa unification of type:

\[ h_b(M_U) = h_\tau(M_U) \]  

(58)

To discuss the implications of this hypothesis, we need the renormalization group evolution of these couplings down to the weak scale. For this purpose, we need the R.G.E’s for these couplings:

\[ 2\pi \frac{d \ln Y_b}{dt} = 6 Y_b + Y_t - \frac{7}{15} \alpha_1 - \frac{16}{3} \alpha_3 - 3 \alpha_2 \]  

(59)

\[ 2\pi \frac{d \ln Y_\tau}{dt} = 4 Y_\tau - \frac{9}{5} \alpha_1 - 3 \alpha_2 \]

\[ 2\pi \frac{d \ln Y_t}{dt} = 6 Y_t + Y_b - \frac{13}{15} \alpha_1 - \frac{16}{3} \alpha_3 - 3 \alpha_2 \]

where we have defined \( Y_i \equiv \frac{h_i^2}{4\pi} \). Subtracting the first two equations in Eq. (59) and defining \( R_{b/\tau} \equiv \frac{Y_b}{Y_\tau} \), one finds that

\[ 2\pi \frac{d}{dt}(R_{b/\tau}) \simeq (Y_t - \frac{16}{3} \alpha_3) \]  

(60)

Solving this equation using the Yukawa unification condition, we find that

\[ \frac{m_b}{m_\tau}(M_Z) = (R_{b/\tau}(M_Z))^{1/2} = A_t^{-1/2} \left( \frac{\alpha_3(M_Z)}{\alpha_3(M_U)} \right)^{8/9} \]  

(61)

where \( A_t = e^{\frac{\pi}{4} \int_{M_Z}^{M_U} \frac{d}{d\mu} Y_\tau \, d\mu} \). Using the value of \( \alpha_u \) from MSSM grand unification, we find that \( \frac{m_b}{m_\tau}(M_Z) \simeq 2.5 A_t^{-1/2} \). The observed value of \( \frac{m_b}{m_\tau}(M_Z) \simeq 1.62 \). So it is clear that a significant contribution from the running of the top Yukawa is needed and this is lucky since the top quark is now known to have mass of \( \sim 175 \) GeV implying an \( h_t \simeq 1 \). One way to estimate the \( A_t \) is to assume that \( h_t(M_U) = 3 \), which case one has \[ A_t^{-1/2} \simeq .85 \] making \( \frac{m_b}{m_\tau} \) closer to observations.
It is worth pointing out that both the top Yukawa as well as the gauge contributions depend on whether there exist an intermediate scale. The modified formula in that case is

\[
\frac{m_t}{m_T}(M_Z) = \left( A_t^Z A_t^{1U} \right)^{-1/2} \left( \frac{\alpha_3(M_Z)}{\alpha_3(M_T)} \right)^{8/9} \left( \frac{\alpha_3(M_I)}{\alpha_3(M_U)} \right)^{8/3} \]

(62)

(A) Top Yukawa coupling and its infrared fixed point

It was noted by Hill and Pendleton and Ross for large Yukawa couplings, \( h_t \), regardless of how large the asymptotic value is, the low energy value determined by the RGE’s is a fixed value and one can therefore use this observation to predict the top quark mass. To see this in detail, let us define a parameter \( \rho_t = Y_t/\alpha_3 \). Using the RGE’s for \( Y_t \) and \( \alpha_3 \), we can then write

\[
\alpha_3 \frac{d\rho_t}{d\alpha_3} = -2\rho_t (\rho_t - \frac{7}{18})
\]

(63)

The solution of this equation is

\[
\rho_t(\alpha_3) = \frac{7/8}{1 - \left(1 - \frac{7}{18\rho_{t0}}\right)(\frac{\alpha_3}{\alpha_{30}})^{-7/9}}
\]

(64)

where \( \rho_{t0} = \rho_t(\Lambda) \) and \( \alpha_{30} = \alpha_3(\Lambda) \). As we move to smaller \( \mu \)’s, \( \alpha_3 \) increases and as \( \alpha_3 \to \infty \), \( \rho_t \to 7/18 \). This leads to \( m_t = 129\sin\beta \) GeV which is much smaller than the observed value. Does this mean that this idea does not work? The answer is no because, strictly, at \( m_t(m_t) \), the \( \alpha_3 \) is far from being infinity. A more sensible thing to do is to use the RGE’s for \( Y_t \) and assume that at \( \Lambda \gg M_Z, Y_t \gg \alpha_3 \) so that for very large \( \mu \), we have

\[
\frac{dY_t}{dt} \sim \frac{3Y_t^2}{\pi}
\]

(65)

As a result, as we move down from \( \Lambda \), first \( Y_t \) will decrease till it becomes comparable to \( \alpha_3 \) after which, it will settle down to the value \( 6Y_t = 16/3\alpha_3 \) for which \( Y_t \) stops running. This leads to a prediction of \( m_t \approx 196\sin\beta \) GeV, which is more consistent with observations. Note incidentally that if we applied the same arguments to the standard model, we would obtain \( m_t \approx 278 \) GeV, which is much too large. Could this be an indication that supersymmetry is the right way to go in understanding the top quark mass?
Finally, we wish to very briefly mention that one could have demanded complete Yukawa unification as is predicted by simple SO(10) models:

\[ h_t(M_U) = h_b(M_U) = h_\tau(M_U) \equiv h_U \] (66)

Extrapolating this relation to \( M_Z \) one could obtain \( m_t, m_b, m_\tau \) in terms of only two parameters \( h_U \) and \( \tan\beta \). This would be a way to also predict \( m_t \). This is therefore an attractive idea. But getting the electroweak symmetry breaking in this scenario is very hard since both \( m_{\tilde H_u}^2 \) and \( m_{\tilde H_d}^2 \) run parallel to each other except for a minor difference arising from the \( U(1)_Y \) effects. One therefore has to make additional assumptions to understand the electroweak symmetry breaking out of radiative corrections.

3 Supersymmetric SU(5)

The simplest supersymmetric grand unification model is based on the simple group SU(5) and it embodies many of the unification ideas discussed in the previous chapter. It is assumed that at the GUT scale \( M_U, SU(5) \) gauge symmetry breaks down to MSSM as follows:

\[ SU(5) \rightarrow SU(3)_c \times SU(2)_L \times U(1)_Y \] (67)

The unification ideas of the previous section tell us that the single gauge coupling at the GUT scale branches down to the three couplings of the standard model.

3.1 Particle assignment and symmetry breaking

To discuss further properties of the model, we discuss the assignment of the matter fields as well as the Higgs superfields to the simplest representations necessary. The matter fields are assigned to the \( \tilde 5 \equiv \tilde F \) and \( 10 \equiv 10 \) dimensional representations whereas the Higgs fields are assigned to \( \Phi \equiv 45, H \equiv 5 \) and \( \bar H \equiv 5 \) representations.

**Matter Superfields:**

\[
\begin{pmatrix}
  d_1^c \\
  d_2^c \\
  d_3^c \\
  e^- \\
  \nu
\end{pmatrix}
\] \( T\{10\} = \begin{pmatrix}
  0 & u_3^c & -u_2^c & u_1 & d_1 \\
  -u_3^c & 0 & u_1^c & u_2 & d_2 \\
  u_2^c & -u_1^c & 0 & u_3 & d_3 \\
  -u_1 & -u_2 & u_3 & 0 & e^+ \\
  -d_1 & -d_2 & -d_3 & -e^+ & 0
\end{pmatrix} \] (68)
In the following discussion, we will choose the group indices as $\alpha, \beta$ for SU(5); (e.g. $H^\alpha, \bar{H}^\alpha, F^\alpha_T = -T^{\beta\alpha}$); $i, j, k, \ldots$ will be used for $SU(3)_c$ indices and $p, q$ for $SU(2)_L$ indices.

To discuss symmetry breaking and other dynamical aspects of the model, we choose the superpotential to be:

$$W = W_Y + W_G + W_h + W_t$$

where

$$W_Y = h_{ab} \epsilon_{\alpha\beta\gamma\delta\sigma} T_{\alpha a} T_{\beta b} H^\sigma + h_{ab} T^{\alpha\beta} \bar{F}_\alpha \bar{H}_\beta$$

($a, b$ are generation indices). This part of the superpotential is responsible for giving mass to the fermions.

$$W_G = z \text{Tr} \Phi + x \text{Tr} \Phi^2 + y \text{Tr} \Phi^3 + \lambda_1 (H \Phi \bar{H} + M H \bar{H})$$

This part of the superpotential is responsible for symmetry breaking and getting light Higgs doublets below $M_U$. Note that although $\text{Tr} \Phi = 0$ the $z$-term added as a Lagrange multiplier to enforce this constraint during potential minimization. Of the rest of the superpotential $W_h$ is the Hidden sector superpotential responsible for supersymmetry breaking and $W_t$ denotes the R-parity breaking terms which will be discussed later. We are looking for the following symmetry breaking chain:

$$SU(5) \times SUSY \rightarrow \langle \Phi \rangle \neq 0 \rightarrow G_{std} \times SUSY$$

To study this we have to use $W_G$ and calculate the relevant F-terms and set them to zero to maintain supersymmetry down to the weak scale.

$$F^{\alpha}_{\beta, \gamma} = z \delta^{\alpha}_{\beta} + 2x \Phi^\beta_{\alpha} + 3y \Phi^\gamma_{\alpha} \Phi^\beta_{\beta} = 0$$

Taking $\langle Tr \Phi \rangle = 0$ implies that $z = -\frac{4}{3} y < Tr \Phi^2 >$. If we assume that $\text{Diag} < \Phi > = (a_1, a_2, a_3, a_4, a_5)$, then one has the following equations:

$$\Sigma_i a_i = 0$$

$$z + 2x a_i + 3y a_i^2 = 0$$

with $i = 1, \ldots, 5$. Thus we have five equations and two parameters. There are therefore three different choices for the $a_i$'s that can solve the above equations and they are: Case (A):

$$\langle \Phi \rangle = 0$$

$$29$$
In this case, SU(5) symmetry remains unbroken. Case (B):

$$\text{Diag} \langle \Phi \rangle = (a, a, a, a, -4a)$$  \hspace{1cm} (76)

In this case, SU(5) symmetry breaks down to $SU(4) \times U(1)$ and one can find $a = \frac{2x}{3y}$. Case (C):

$$\text{Diag} \langle \Phi \rangle = (b, b, b, \frac{3}{2}b, -\frac{3}{2}b)$$  \hspace{1cm} (77)

This is the desired vacuum since SU(5) in this case breaks down to $SU(3)_c \times SU(2)_L \times U(1)_Y$ gauge group of the standard model. The value of $b = \frac{3x}{3y}$ and we choose the parameters $x$ to be order of $M_U$. In the supersymmetric limit all vacua are degenerate.

### 3.2 Low energy spectrum and doublet-triplet splitting

Let us next discuss whether the MSSM arises below the GUT scale in this model. So far we have only obtained the gauge group. The matter content of the MSSM is also already built into the $\bar{F}$ and $T$ multiplets. The only remaining question is that of the two Higgs superfields $H_u$ and $H_d$ of MSSM. They must come out of the $H$ and the $\bar{H}$ multiplets. Writing $H \equiv \left(\begin{array}{c} \zeta_u \\ H_u \end{array}\right)$ and $\bar{H} \equiv \left(\begin{array}{c} \zeta_d \\ H_d \end{array}\right)$. From $W_G$ substituting the $\langle \Phi \rangle$ for case (C), we obtain,

$$W_{eff} = \lambda(b + M)\zeta_u\zeta_d + \lambda(-3/2b + M)H_uH_d$$  \hspace{1cm} (78)

If we choose $3/2b = M$, then the massless standard model doublets remain and every other particle of the SU(5) model gets large mass. The uncomfortable aspect of this procedure is that the adjustment of the parameters is done by hand does not emerge in a natural manner. This procedure of splitting of the color triplets $\zeta_{u,d}$ from $SU(2)_L$ doublets $H_{u,d}$ is called doublet-triplet splitting and is a generic issue in all GUT models. An advantage of SUSY GUT’s is that once the fine tuning is done at the tree level, the nonrenormalization theorem of the SUSY models preserves this to all orders in perturbation theory. This is one step ahead of the corresponding situation in non- SUSY GUT’s, where the cancellation between $b$ and $M$ has to be done in each order of perturbation theory. A more satisfactory situation would be where the doublet-triplet splitting emerges naturally due to requirements of group theory or underlying dynamics.
3.3 Fermion masses and Proton decay

Effective superpotential for matter sector at low energies then looks like:

\[ W_{\text{matter}} = h_u Q H_u u^c + h_d Q H_d d^c + h_l L H_d e^c + \mu H_u H_d \]  

(79)

Note that \( h_d \) and \( h_l \) arise from the \( T \bar{F} \Phi \bar{H} \) coupling and this satisfy the relation \( h_d = h_l \). Similarly, \( h_u \) arises from the \( TTH \) coupling and therefore obeys the constraint \( h_u = h_u^L \). (None of these constraints are present in the MSSM). The second relation will be recognized by the reader as a partial Yukawa unification relation and we can therefore use the discussion of Section 2 to predict \( m_\tau \) in terms of \( m_b \). The relation between the Yuakawa couplings however hold for each generation and therefor imply the undesirable relations among the fermion masses such as \( m_d/m_s = m_e/m_\mu \). This relation is independent of the mass scale and therefore holds also at the weak scale. It is in disagreement with observations by almost a factor of 15 or so. This a major difficulty for minimal SU(5) model. This problem does not reflect any fundamental difficulty with the idea of grand unification but rather with this particular realization. In fact by including additional multiplets such as \( 45 \) in the theory, one can avoid this problem. Another way is to add higher dimensional operators to the theory such as \( T \bar{F} \Phi \bar{H}/M_P \), which can be of order of a 0.1 GeV or so and could be used to fix the muon mass prediction from SU(5).

The presence of both quarks and leptons in the same multiplet of SU(5) model leads to proton decay. For detailed discussions of this classic feature of GUTs, see for instance [4]. In non-SUSY SU(5), there are two classes of Feynman diagrams that lead to proton decay in this model: (i) the exchange of gauge bosons familiar from non-SUSY SU(5) where effective operators of type \( e^+ u d^+ u \) are generated; and (ii) exchange of Higgs fields. In the supersymmetric case there is an additional source for proton decay coming from the exchange of Higgsinos, where \( QQH \) and \(QLH\) via \(H \bar{H}\) mixing generate the effective operator \( QQQL/M_H \) that leads to proton decay. In fact, this turns out to give the dominant contribution.

The gauge boson exchange diagram leads to \( p \rightarrow e^+ \pi^0 \) with an amplitude

\[ M_{p \rightarrow e^+ \pi^0} = \frac{4\pi \alpha_{\mu}}{M_U^2} \]

This leads to a prediction for the proton lifetime of:

\[ \tau_p = 4.5 \times 10^{29\pm 7} \left( \frac{M_U}{2.1 \times 10^{14} \text{ GeV}} \right)^4 \]

(80)

For \( M_U \approx 2 \times 10^{16} \text{ GeV} \), one gets \( \tau_p = 4.5 \times 10^{37\pm 7} \text{ yrs} \). This far beyond the capability of SuperKamiokande experiment, whose ultimate limit is \( \sim 10^{34} \) years.
Turning now to the Higgsino exchange diagram, we see that the amplitude for this case is given by:

\[ M \simeq \frac{h_u h_d}{M_H} \cdot \frac{m_{\text{gaugino}} g^2}{16\pi^2 M_Q^2} \]  

(81)

In this formula there is only one heavy mass suppression. Although there are other suppression factors, they are not as potent as in the gauge boson exchange case. As result this dominates. A second aspect of this process is that the final state is \( \nu K^+ \) rather than \( e^+ \pi^0 \). This can be seen by studying the effective operator that arises from the exchange of the color triplet fields in the \( 5 + \bar{5} \) i.e. \( O_{\Delta B=1} = QQQL \) where \( Q \) and \( L \) are all superfields and are therefore bosonic operators. In terms of the isospin and color components, this looks like \( \epsilon^{ijk} u_i u_j d_k e^- \) or \( \epsilon^{ijk} u_i d_j d_k \nu \). It is then clear that unless the two \( u \)'s or the \( d \)'s in the above expressions belong to two different generations, the operators vanishes due to color antisymmetry. Since the charm particles are heavier than the protons, the only contribution comes from the second operators and the strange quark has to be present (i.e. the operator is \( \epsilon^{ijk} u_i d_j s_k \nu \)). Hence the new final state. Detailed calculations show that for this decay lifetime to be consistent with present observations, one must have \( M_H > M_U \) by almost a factor of 10. This is somewhat unpleasant since it would require that some coupling in the superpotential has to be much larger than one.

### 3.4 Other aspects of SU(5)

There are several other interesting implications of SU(5) grand unification that makes this model attractive and testable. The model has very few parameters and hence is very predictive. The MSSM has got more than a hundred free parameters, that makes such models experimentally quite fearsome and of course hard to test. On the other hand, once the model is embedded into SUSY SU(5) with Polonyi type supergravity, the number of parameters reduces to just five: they are the \( A, B, m_{3/2} \) which parameterize the effects of supergravity discussed in section I, \( \mu \) parameter which is the \( H_u H_d \) mixing term in the superpotential also present in the superpotential and \( m_\lambda \), the universal gaugino mass. This reduction in the number of parameters has the following implications:

(i) **Gaugino unification:**

At the GUT scale, we have the three gaugino masses equal (i.e. \( m_{\lambda_1} = m_{\lambda_2} = m_{\lambda_3} \)). There value at the weak scale can be predicted by using the RG
running as follows:

$$\frac{dm_{\lambda_i}}{dt} = \frac{b_i}{2\pi} \alpha_i m_{\lambda_i} \quad (82)$$

Solving these equations, one finds that at the weak scale, we have

$$m_{\lambda_1} : m_{\lambda_2} : m_{\lambda_3} = \alpha_1 : \alpha_2 : \alpha_3 \quad (83)$$

Thus discovery of gaugino’s will test this formula and therefore SU(5) grand unification.

(ii) Prediction for squark and slepton masses

At the supersymmetry breaking scale, all scalar masses in the simple supergravity schemes are equal. Again, one can predict their weak scale values by the RGE extrapolation. One finds the following formula:

$$m_{\tilde{Q}}^2 = m_{3/2}^2 + m_Q^2 + \frac{\alpha U}{4\pi} \left[ \frac{8}{3} f_3 + \frac{3}{2} f_2 + \frac{1}{30} f_1 \right] m_{\lambda U}^2 + Q_Z^2 M_Z^2 \cos^2 2\beta \quad (84)$$

where $Q_Z^u = \frac{1}{2} - \frac{2}{3} \sin^2 \theta_W$ and $Q_Z^d = -\frac{1}{2} + \frac{1}{3} \sin^2 \theta_W$ and $f_k = \frac{r(2-b_k t)}{1+b_k t^2}$ and $b_k$ are the coefficients of the RGE’s for coupling constant evolutions given earlier. A very obvious formula for the sleptons can be written down. It omits the strong coupling factor. A rough estimate gives that $m_{\tilde{\ell}}^2 \approx m_{3/2}^2 / 2$ and $m_{\tilde{Q}}^2 \approx m_{3/2}^2 + 4m_{\lambda U}^2$. This could therefore serve as independent tests of the SUSY SU(5).

3.5 Problems and prospects for SUSY SU(5)

While the simple SUSY SU(5) model exemplifies the power and utility of the idea of SUSY GUTs, it also brings to the surface some of the problems one must solve if the idea eventually has to be useful. Let us enumerate them one by one and also discuss the various ideas proposed to overcome them.

(i) R-parity breaking:

There are renormalizable terms in the superpotential that break baryon and lepton number:

$$W' = \lambda_{abc} T_a \tilde{F}_b \tilde{F}_c \quad (85)$$
When written in terms of the component fields, this leads to R-parity breaking terms of the MSSM such as $L_{a}L_{b}e_{c}^{c}$, $QLd^{c}$ as well as $u^{c}d^{c}d^{c}$ etc. The new point that results from grand unification is that there is only one coupling parameter that describes all three types of terms and also the coupling $\lambda$ satisfies the antisymmetry in the two generation indices $b, c$. This total number of parameters that break R-parity are nine instead of 45 in the MSSM. There are also non-renormalizable terms of the form $T\bar{F}F(\Phi/M_{P})^{n}$, which are significant for $n = 1, 2, 3, 4$ and can add different complexion to the R-parity violation. Thus, the SUSY SU(5) model does not lead to an LSP that is naturally stable to lead to a CDM candidate. As we will see in the next section, the SO(10) model provides a natural solution to this problem if only certain Higgs superfields are chosen.

(ii) Doublet-triplet splitting problem:

We saw earlier that to generate the light doublets of the MSSM, one needs a fine tuning between the two parameters $3/2\lambda b$ and $M$ in the superpotential. However once SUSY breaking is implemented via the hidden sector mechanism one gets a SUSY breaking Lagrangian of the form:

$$L_{SB} = A\lambda\bar{H}\Phi H + BM\bar{H}H + h.c.$$  \(86\)

where the symbols in this equation are only the scalar components of the superfields. In general supergravity scenarios, $A \neq B$. As a result, when the Higgsinos are fine tuned to have mass in the weak scale range, the same fine tuning does not leave the scalar doublets at the weak scale.

There are two possible ways out of this problem: we discuss them below.

(iiA) Sliding singlet

The first way out of this is to introduce a singlet field $S$ and choose the superpotential of the form:

$$W_{DT} = 2\bar{H}\Phi H + S\bar{H}H$$  \(87\)

The supersymmetric minimum of this theory is given by:

$$F_{H} = H_{u}(-3b+ <S>) = 0$$  \(88\)

The $F_{H}$ equation is automatically satisfied when color is unbroken as is required to make the theory physically acceptable. We then see that one then automatically gets $<S> = 3b$ which is precisely the condition that keeps the doublets...
light. Thus the doublets remain naturally of the weak scale without any need for fine tuning. This is called the sliding singlet mechanism. In this case the supersymmetry breaking at the tree level maintains the massless of the MSSM doublets for both the fermion as well as the bosonic components. There is however a problem that arises once one loop corrections are included- because they lead to corrections for the $<S>$ vev of order $\frac{1}{16\pi^2}m_{3/2}M_U$ which then produces a mismatch in the cancellation of the bosonic Higgs masses. One is back to square one!

(iiB) Missing partner mechanism:

A second mechanism that works better than the previous one is the so called missing partner mechanism where one chooses to break the GUT symmetry by a multiplet that has coupling to the $H$ and $\bar{H}$ and other multiplets in such a way that once SU(5) symmetry is broken, only the color triplets in them have multiplets in the field it couples to pair up with but not weak doublets. As a result, the doublet naturally light. An example is provided by adding the 50, 50 (denoted by $\Theta^{\alpha\beta\gamma\delta\sigma}$ and $\bar{\Theta}$ respectively) and replacing 24 by the 75 (denoted $\Sigma$) dimensional multiplet. Note that 75 dim multiplet has a standard model singlet in it so that it breaks the SU(5) down to the standard model gauge group. At the same time 50 has a color triplet only and no doublet. The 50,75,5 coupling enables the color triplet in 50 and 5 to pair up leaving the weak doublet in $\bar{H}$ light. The superpotential in this case can be given by

$$W_G = \lambda_1 \Theta \Sigma H + \lambda_2 \bar{\Theta} \Sigma \bar{H} + M \Theta \bar{\Theta} + f(\Sigma)$$

This mechanism can be applied in the case of other groups too.

(iii) Baryogenesis problem

There are also other problems with the SUSY SU(5) model that suggest that other GUT groups be considered. One of them is the problem with generating the baryon asymmetry of the universe in a simple manner. The point is that if baryon asymmetry in this model is generated at the GUT scale as is customarily done, then the there must also simultaneously be a lepton asymmetry such that $B - L$ symmetry is preserved. The reason for this is that all interactions of the simple SUSY models conserve B-L symmetry. As a result, we can write the $n_B = \frac{1}{2}n_{B - L} + \frac{1}{2}n_{B + L} = \frac{1}{2}n_{B + L}$. The problem then is that the sphaleron interactions which are in equilibrium for $10^2 GeV \leq T \leq 10^{12} GeV$, will erase the $n_{B + L}$ since they violate the $B + L$ quantum number. Thus the GUT scale baryon asymmetry cannot survive below the weak scale. Of course
one could perhaps generate baryons at the weak scale using the sphaleron processes. But no simple and convincing mechanism seems to have been in place yet. Thus it may be wise to look at higher unification groups.

(iv) Neutrino masses

Finally, in the SU(5) model there seems to no natural mechanism for generating neutrino masses although using the R-parity violating interactions for such a purpose has often been suggested. One would then have to accept the required smallness of their couplings has to be put in by hand.

(v) Vacuum degeneracy and supergravity effects

A generic cosmological problem of most SUSY GUT’s is the vacuum degeneracy obtained in the case of the SU(5) model in the supersymmetric limit discussed in section 3.2 above. Recall that SU(5) symmetry breaking via the 24 Higgs superfield leaves three vacua i.e. the SU(5) , SU(4) × U(1) and the SU(3)c × SU(2)L × U(1)y ones with same vacuum energy. The question then is how does the universe settle down to the standard model vacuum. It turns out that once the supergravity effects are included, the three vacua have different energies coming from the $-\frac{3}{M_P^2} |W|^2$ term in the effective bosonic potential. Using the values of the parameters a and b above that characterise the vacua, we find these energies to be:

$$<\Phi>= 0 : V_0 = 0$$  

$$SU(4) \times U(1) : V_0 = -3 \left( \frac{80}{243} \right)^2 \frac{x^6}{M_P^2 y^4}$$

$$SU(3)_c \times SU(2)_L \times U(1)_Y : V_0 = -3 \frac{1600}{81} \frac{x^6}{M_P^2 y^4}$$

This would appear quite interesting since indeed the standard model vacuum has the lowest vacuum energy. However that is misleading since this evaluation is done prior to the setting of the cosmological constant to zero. Once that is done, the standard model indeed acquires the highest vacuum energy. Thus this remains a problem. One way to avoid this would be to imagine that the standard model is indeed stuck in the wrong vacuum but the tunneling probability to other vacua is negligible or at least it is such that the tunnelling time is longer than the age of the universe.

It is worth pointing out that in the case where the SU(5) symmetry is broken by the 75 dim. multiplet, there is no SU(4) × U(1) inv. vacuum. Similarly one can imagine eliminating the SU(5) inv vacuum by adding to the superpotential terms like $S(\Sigma^2 - M_P^2)$. 

36
4 Supersymmetric SO(10)

In this section, we like to discuss supersymmetric SO(10) models which have a number of additional desirable features over SU(5) model. For instance, all the matter fermions fit into one spinor representation of SO(10); secondly, the SO(10) spinor being 16-dimensional, it contains the right-handed neutrino leading to nonzero neutrino masses. The gauge group of SO(10) is left-right symmetric which has the consequence that it can solve the SUSY CP problem and R-parity problem etc. the MSSM unlike the SU(5) model. Before proceeding to a discussion of the model, let us briefly discuss the group theory of SO(10).

4.1 Group theory of SO(10)

The SO(2N) group is defined by the Clifford algebra of 2N elements, $\Gamma_a$ which satisfy the following anti-commutation relations:

$$[\Gamma_a, \Gamma_b]_+ = 2\delta_{ab}$$ (91)

where $a, b$ go from 1...2N. The generators of SO(2N) group are then given by

$$\Sigma_{ab} \equiv \frac{1}{2i}[\Gamma_a, \Gamma_b]_-.$$ The study of the spinor representations and simple group theoretical manipulations with SO(2N) is considerably simplified if one uses the SU(N) basis for SO(2N) [51].

To discuss the SU(N) basis, let us introduce N anticommuting operators $\chi_i$ and $\chi_i^\dagger$ satisfying the following anticommuting relations:

$$[\chi_i, \chi_j^\dagger]_+ = \delta_{ij}$$ (92)

We can then express the elements of the Clifford algebra $\Gamma_a$’s in terms of these fermionic operators as follows:

$$\Gamma_{2i-1} = \frac{\chi_i - \chi_i^\dagger}{2i}$$

$$\Gamma_{2i} = \frac{\chi_i + \chi_i^\dagger}{2}$$ (93)

The spinor representations of the SO(10) group can be obtained using this formalism as follows:

$$\Psi = \begin{pmatrix}
\chi_i^\dagger |0 > \\
\chi_i^\dagger \chi_j^\dagger |0 > \\
\chi_j^\dagger \chi_i^\dagger \chi_j^\dagger |0 > \\
\chi_j^\dagger \chi_i^\dagger \chi_j^\dagger \chi_i^\dagger |0 >
\end{pmatrix}$$ (94)
By simple counting, one can see that this is a 16 dimensional representation. The states in the 16-dim. spinor have the right quantum numbers to accommodate the matter fermions of one generation. The different particle states can be easily identified: e.g. $e^- = \chi_4^\dagger|0>$; $d_i^c = \chi_i^\dagger|0>$; $u_i = \chi_2^\dagger\chi_3^\dagger\chi_5^\dagger|0>$; $e^+ = \chi_1^\dagger\chi_2^\dagger\chi_3^\dagger|0>$ etc.

Other representations such as 10 are given simply by the $\Gamma_a$, 45 by $[\Gamma_a, \Gamma_b]$ etc. In other words, they can be denoted by vectors with totally antisymmetric indices: The tensor representations that will be necessary in our discussion are 10 $\equiv H_a$; 45 $\equiv \Lambda_{ab}$, 120 $\equiv \Lambda_{abc}$, 210 $\equiv \Delta_{abcd}$.

(All indices here are totally antisymmetric). One needs a charge conjugation operator to write Yukawa couplings such as $\Psi\bar{\Psi}H$ where $H \equiv 10$. It is given by $C \equiv \Pi I_{2i-1}$ with $i = 1,..5$. The generators of SU(4) and SU(2)$_L \times$ SU(2)$_R$ can be written down in terms of the $\chi$'s. The fact that SU(4) is isomorphic to SO(6) implies that the generators of SU(4) will involve only $\chi_i$ and its hermitean conjugate for $i = 1,2,3$ whereas the SU(2)$_L \times$ SU(2)$_R$ involves only $\chi_p$ (and its h.c.) for $p = 4,5$. The SU(2)$_L$ generators are: $I^+_L = \chi_4^\dagger\chi_5$ and $I^-_L$ and $I_{3L}$ can be found from it. Similarly, $I^+_R = \chi_1^\dagger\chi_4^\dagger$ and the other right handed generators can be found from it. For instance $I^R_{3R} = \frac{1}{2}[I^+_R - I^-_R]$ etc. We also have

$$B - L = -\frac{1}{3}\Sigma_i \chi_i^\dagger \chi_i + \Sigma_p \chi_p^\dagger \chi_p$$

$$Q = \frac{1}{3}\Sigma_i \chi_i^\dagger \chi_i - \chi_4^\dagger \chi_4$$

(95)

This formulation is one of many ways one can deal with the group theory of SO(2N). An advantage of of the spinor basis is that calculations such as those for 16.10.16 need only manipulations of the anticommutation relations among the $\chi$'s and bypass any matrix multiplication.

As an example, suppose we want to evaluate up and down quark masses induced by the weak scale vev's from the 10 higgs. We have to evaluate $\Psi C T_a \bar{\Psi} H_a$. To see which components of H corresponds to electroweak doublets, let us note that SO(10) $\rightarrow$ SO(6) $\times$ SO(4); denote $a = 1,..6$ as the SO(6) indices and $p = 7..10$ as the SO(4) indices. Now SO(6) is isomorphic to SU(4) which we identify as SU(4) color with lepton number as fourth color and SO(4) is isomorphic to SU(2)$_L \times$ SU(2)$_R$ group. To evaluate the above matrix element, we need to give vev to $H_{a,10}$ since all other elements have electric charge. This can be seen from the SU(5) basis, where $\chi_5$, corresponding to the neutrino has zero charge whereas all the other $\chi$'s have electric charge as can be seen from the formula for electric charge in terms of $\chi$'s given above. Thus all one needs to evaluate is typically a matrix element of the type
\(< 0|\chi_1 \Gamma_9 C \chi_2 \chi_3 \chi_4^\dagger |0 >. \) In this matrix element, only terms \(\chi_5\) from \(\Gamma_9\) and 
\(\chi_2 \chi_3 \chi_4 \chi_1^\dagger \chi_5^\dagger\) will contribute and yield a value one.

4.2 Symmetry breaking and fermion masses

Let us now proceed to discuss the breaking of SO(10) down to the standard model. SO(10) contains the maximal subgroups \(SU(5) \times U(1)\) and 
\(SU(4)_c \times SU(2)_L \times SU(2)_R \times Z_2\) where the \(Z_2\) group corresponds to charge conjugation. The \(SU(4)_c\) group contains the subgroup \(SU(3)_c \times U(1)_{B-L}\). Before discussing the symmetry breaking, let us digress to discuss the \(Z_2\) subgroup and its implications.

The discrete subgroup \(Z_2\) is often called D-parity in literature. Under D-parity, \(u \rightarrow u^c; e \rightarrow e^c\) etc. In general the D-parity symmetry and the \(SU(2)_R\) symmetry can be broken separately from each other. This has several interesting physical implications. For example if D-parity breaks at a scale \((M_P)\) higher than \(SU(2)_R\) \((M_R)\) (i.e. \(M_P > M_R\)), then the Higgs boson spectrum gets asymmetrized and as a result, the two gauge couplings evolve in a different manner. At \(M_R\), one has \(g_L \neq g_R\). The SO(10) operator that implements the D-parity operation is given by \(D \equiv \Gamma_2 \Gamma_3 \Gamma_6 \Gamma_7\). The presence of D-parity group below the GUT scale can lead to formation of domain walls bounded by strings. This can be cosmological disaster if \(M_P = M_R\) whereas this problem can be avoided if \(M_P > M_R\). Another way to avoid such problem will be to invoke inflation with a reheating temperature \(T_R \leq M_R\).

There are therefore many ways to break SO(10) down to the standard model. Below we list a few of the interesting breaking chains along with the SO(10) multiplets whose vev's lead to that pattern.

(A) \(SO(10) \rightarrow SU(5) \rightarrow G_{STD}\)

The Higgs multiplet responsible for the breaking at the first stage is a \(16\) dimensional multiplet (to be denoted \(\psi_H\)) which has a field with the quantum number of \(\nu^c\) which is an SU(5) singlet but with non-zero \(B - L\) quantum number. The second stage can be achieved by

\[16_H \rightarrow 1_{-5} + 10_{-1} + \bar{5}_{+3}\]  (96)

The breaking of the SU(5) group down to the standard model is implemented by the \(45\)-dimensional multiplet which contains the \(24\) dim. representation of SU(5), which as we saw in the previous section contains a singlet of the
standard model group. In the matrix notation, we can write breaking by $45$ as $<A> = i\tau_2 \times \text{Diag}(a, a, a, b, b)$ where $a \neq 0$ whereas we could have $b = 0$ or nonzero.

A second symmetry breaking chain of physical interest is:

(B) $SO(10) \rightarrow G_{224} \rightarrow G_{STD}$

where we have denoted $G_{224} = SU(2)_L \times SU(2)_R \times SU(4)_c \times Z_2$. We will use this obvious shorthand for the different subgroups. This breaking is achieved by the Higgs multiplet

$$54 = (1,1,1) + (3,3,1) + (1,1,20') + (2,2,6)$$  \hspace{1cm} (97)

The second stage of the breaking of $G_{224}$ down to $G_{STD}$ is achieved in one of two ways and the physics in both cases are very different as we will see later:

(i) $16 + \bar{16}$ or (ii) $126 + \bar{126}$. For clarity, let us give the $G_{224}$ decomposition of the $16$ and $126$.

$$16 = (2,1,4) + (1,2,\bar{4})$$  \hspace{1cm} (98)

$$126 = (3,1,10) + (1,3,\bar{10}) + (2,2,15) + (1,1,6)$$

In matrix notation, we have

$$<54> = \text{Diag}(2a, 2a, 2a, 2a, 2a, 2a, 2a, -3a, -3a, -3a, -3a)$$  \hspace{1cm} (99)

and for the $126$ case it is the $\nu^c\nu^c$ component that has nonzero vev.

It is important to point out that since the supersymmetry has to be maintained down to the electroweak scale, we must consider the Higgs bosons that reduce the rank of the group in pairs (such as $16 + \bar{16}$). Then the D-terms will cancel among themselves. However, such a requirement does not apply if a particular Higgs boson vev does not reduce the rank.

(C) $SO(10) \rightarrow G_{231} \rightarrow G_{STD}$

This breaking is achieved by a combination of $54$ and $45$ dimensional Higgs representations. Note the absence of the $Z_3$ symmetry after the first stage of breaking. This is because the $(1,1,15)$ (under $G_{224}$) submultiplet that breaks the $SO(10)$ symmetry is odd under the D-parity. The second stage breaking is as in the case (B).

(D) $SO(10) \rightarrow G_{224} \rightarrow G_{STD}$
Note the absence of the D-parity in the second stage. This is achieved by the Higgs multiplet $210$ which decomposes under $G_{224}$ as follows:

\[210 = (1, 1, 15) + (1, 1, 1) + (2, 2, 10) + (2, 2, 10) + (1, 3, 15) + (3, 1, 15) + (2, 2, 6)\]  

(100)

The component that acquires vev is $<\Sigma_{78910}> \neq 0$.

It is important to point out that since the supersymmetry has to be maintained down to the electroweak scale, we must consider the Higgs bosons that reduce the rank of the group in pairs (such as $16 + \bar{16}$). Then the D-terms will cancel among themselves. However, such a requirement does not apply if a particular Higgs boson vev does not reduce the rank.

Let us now proceed to the discussion of fermion masses. As in all gauge models, they will arise out of the Yukawa couplings after spontaneous symmetry breaking. To obtain the Yukawa couplings, we first note that $16 \times 16 = 10 + 120 + 126$. Therefore the gauge invariant couplings are of the form $16.16.10 \equiv \Psi^T C^{-1} \Gamma_a \Psi H_a$; $16.16.120 \equiv \Psi \Gamma_a \Gamma_b \Gamma_c \Psi \Lambda_{abc}$ and $16.16.126 \equiv \Psi \Gamma_a \Gamma_b \Gamma_c \Gamma_d \Psi \Delta_{abcde}$. We have suppressed the generation indices. Treating the Yukawa couplings as matrices in the generation space, one gets the following symmetry properties for them: $h_{10} = h_{10}^T$; $h_{120} = -h_{120}^T$ and $h_{126} = h_{126}^T$ where the subscripts denote the Yukawa couplings of the spinors with the respective Higgs fields.

To obtain fermion masses after electroweak symmetry breaking, one has to give vevs to the following components of the fields in different cases: $<H_{9, 10}> \neq 0$; $\Lambda_{789, 7810} \neq 0$ or $\Lambda_{129} = \Lambda_{349} = \Lambda_{569} \neq 0$ (or with 9 replaced by 10) and similarly $\Delta_{12789} = \Delta_{34789} = \Delta_{56789} \neq 0$ etc. Several important constraints on fermion masses implied in the SO(10) model are:

(i) If there is only one $10$ Higgs responsible for the masses, then only $<H_{10}> \neq 0$ and has the relation $M_u = M_d = M_e = M_{\nu, \nu}$; where the $M_F$ denote the mass matrix for the F-type fermion.

(ii) If there are two $10$'s, then one has $M_d = M_e$ and $M_u = M_{\nu, \nu}$.

(iii) If the fermion masses are generated by a $126$, then we have the mass relation following from $SU(4)$ symmetry i.e. $3M_d = -M_e$ and $3M_u = -M_{\nu, \nu}$.

It is then clear that, if we have only $10$'s generating fermion masses we have the bad mass relations for the first two generations in the down-electron sector. On the other hand it provides the good $b - \tau$ relation. One way to cure it would be to bring in contributions from the $126$, which split the quark masses from the lepton masses- since in the $G_{224}$ language, it contains $(2, 2, 15)$ component which gives the mass relation $m_e = -3m_d$. This combined with the $10$ contribution can perhaps provide phenomenologically viable fermion masses. With this in mind, we note the suggestion of Georgi and Jarlskog.
who proposed that one should have the $M_d$ and $M_e$ of the following forms to avoid the bad mass relations among the first generations while keeping $b - \tau$ unification:

$$M_d = \begin{pmatrix} 0 & d & 0 \\ d & f & 0 \\ 0 & 0 & g \end{pmatrix}; M_e = \begin{pmatrix} 0 & d & 0 \\ d & -3f & 0 \\ 0 & 0 & g \end{pmatrix}$$ (101)

$$M_u = \begin{pmatrix} 0 & a & 0 \\ a & 0 & b \\ 0 & b & c \end{pmatrix}$$ (102)

These mass matrices lead to $m_b = m_\tau$ at the GUT scale and $m_\mu \approx \frac{1}{9} m_\mu$ which are in much better agreement with observations. There have been many derivations and analyses of these mass matrices in the context of SO(10) models.

4.3 Neutrino masses, R-parity breaking, 126 vrs. 16:

One of the attractive aspects of the SO(10) models is the left-right symmetry inherent in the model. A consequence of this is the complete quark-lepton symmetry in the spectrum. This implies the existence of the right-handed neutrino which as we will see is crucial to our understanding of the small neutrino masses. This comes about via the see-saw mechanism mentioned earlier in section 1. The generic see-saw mechanism for one generation can be seen in the context of the standard model with the inclusion of an extra righthanded neutrino which is a singlet of the standard model group. As is easy to see, if there is a right-handed neutrino denoted as $\nu^c$, then we have additional terms in the MSSM superpotential of the form $h_\nu L H u \nu^c + M \nu^c \nu^c$.

After electroweak symmetry breaking, there emerges a $2 \times 2$ mass matrix for the $(\nu, \nu^c)$ system of the following form:

$$M_\nu = \begin{pmatrix} 0 & h_u v_u \\ h^T_v u & M \end{pmatrix}$$ (103)

This matrix can be diagonalized easily and noting that $M \gg h_u v_u$, we find a light eigenvalue $m_\nu \approx \frac{(h_u v_u)^2}{M}$ and a heavy eigenvalue $\approx M$. The light eigenstate is predominantly the light weakly interacting neutrino and the heavy eigenstate is the superweakly interacting right handed neutrino. Thus without any fine tuning, one sees (using the fact that $m_f \approx h_u v_u$) that $m_\nu \approx m_f^2 / M \ll$
This is known as the see-saw mechanism\cite{25}. For future reference, we note that \( h_u v_u \) for three generations is a matrix and is called the Dirac mass of the neutrino. The left as well as the right handed neutrinos in this case are Majorana neutrinos i.e. they are self conjugate. For detailed discussion the Majorana masses, see Ref.\cite{57}.

While in the context of the standard model it is natural to expect \( M \gg v_u \), we cannot tell what the value of \( M \) is; secondly, the approximation of \( h_u v_u \simeq m_f \) is also a guess. The SO(10) model has the potential to make more quantitative statements about both these aspects of the see-saw mechanism.

To see the implications of embedding see-saw matrix in the SO(10) model, let us first note that if the only source for the quark and charged lepton masses is the 10- dim. rep. of SO(10), then we have a relation between the Dirac mass of the neutrino and the up quark masses:

\[ M = M_{\nu} D. \]

Let us now note that the \( \nu^c \nu^c \) mass term \( M \) arises from the vacuum expectation value (vev) of the \( \nu^c \nu^c \) component of \( \bar{126} \) and therefore corresponds to a fundamental gauge symmetry breaking scale in the theory which can be determined from the unification hypothesis. Thus apart from the coupling matrix of the \( \bar{126} \) denoted by \( f \), everything can be determined. This gives predictive power to the SO(10) model in the neutrino sector. For instance, if we take typical values for the \( f \) coupling to be one and ignore the mixing among generations, then, we get

\begin{align}
 m_{\nu_e} &\simeq m_u^2/10fv_{B-L} \\
 m_{\nu_\mu} &\simeq m_e^2/10fv_{B-L} \\
 m_{\nu_\tau} &\simeq m_t^2/10fv_{B-L}
\end{align}

If we take \( v_{B-L} \simeq 10^{12} \) GeV, then we get, \( m_{\nu_e} \approx 10^{-8} \) eV; \( m_{\nu_\mu} \approx 10^{-4} \) eV and \( m_{\nu_\tau} \approx \) eV. These values for the neutrino masses are of great deal of interest in connection with the solutions to the solar neutrino problem as well as to the hot dark matter of the universe. Things in the SO(10) model are therefore so attractive that one can go further in this discussion and about the prediction for \( v_{B-L} \) in the SO(10) model. The situation here however is more complex and we summarize the situation below.

If the particle spectrum all the way until the GUT scale is that of the MSSM, then both the \( M_U \) and the \( v_{B-L} \) are same and \( \simeq 2 \times 10^{16} \) GeV. On the other hand, if above the \( v_{B-L} \) scale, the symmetry is \( G_{2213} \) and the spectrum has two bidoublets of the SUSYLR theory, \( B-L = \pm 2 \) triplets of both the left and the right handed groups and a color octet, then one can easily see that in the one loop approximation, the \( v_{B-L} \approx 10^{13} \) GeV or so. On the other hand with a slightly more complex system described in section 2, we could get \( v_{B-L} \)
almost down to a few TeV’s. Thus unfortunately, the magnitude of the scale $v_{B-L}$ is quite model dependent.

Finally, it is also worth pointing out that the equality of $M_u$ and $M_{\nu_D}$ is not true in more realistic models. The reason is that if the charged fermion masses arise purely from the $10$-dim. rep.s than one has the undesirable relation $m_d/m_s = m_e/m_\mu$ which was recognized in the SU(5) model to be in contradiction with observations. Therefore in order to predict neutrino masses in the SO(10) model, one needs additional assumptions than simply the hypothesis of grand unification.

(i) Neutrino masses in the case $B - L$ breaking by $16_H$:

As has been noted, it is possible to break $B - L$ symmetry in the SO(10) model by using the $16 + \bar{16}$ pair. This line of model building has been inspired by string models which in the old fashioned fermionic compactification do not seem to lead to $126$ type representation at any level. There have been several realistic models constructed along these lines. In this case, one must use higher dimensional operators to get the $\nu^c$ mass. For instance the operator $16_m \bar{16}_m \bar{16}_H 16_H/M_P l$ after $B - L$ breaking would give rise to a $\nu^c$ mass $\sim v_{B-L}^2/M_P l$. For $v_{B-L} \simeq M_U$, this will lead to $M_{\nu^c} \simeq 10^{13}$ GeV. This then leads to the neutrino spectrum of the above type. Another way to get small neutrino masses in SO(10) models with $16$’s rather than $126$’s without invoking higher dimensional operators is to use the $3 \times 3$ see-saw rather than the two by two one discussed above. To implement the $3 \times 3$ see-saw, one needs an extra singlet fermion and write the following superpotential:

$$W_{33} = h \Psi H \bar{\Psi} + f \bar{\Psi} \bar{H} S + \mu S^2$$  \hspace{1cm} (105)

After symmetry breaking, one gets the following mass matrix in the basis $(\nu, \nu^c, S)$:

$$M_{\nu} = \begin{pmatrix} 0 & h v_u & 0 \\ h v_u & 0 & f \bar{v}_R \\ 0 & f \bar{v}_R & \mu \end{pmatrix}$$  \hspace{1cm} (106)

where $\bar{v}_R$ is the vev of the $16_H$. On diagonalizing for the case $v_u \simeq \mu \ll v_R$, one finds the lightest neutrino mass to be $m_\nu \simeq \frac{\mu h^2 v_u^2}{f v_R}$ and two other heavy eigenstates with masses of order $f v_R$.

(ii) R-parity conservation: automatic vs. enforced:
One distinct advantage of $126$ over $16$ is in the property that the former leads to a theory that conserves R-parity automatically even after $B - L$ symmetry is broken. This is very easy to see as was emphasized in section 1. Recall that $R = (-1)^{3(B - L) + 2S}$. Since the $126$ breaks $B - L$ symmetry via the $\nu^c\nu^c$ component, it obeys the selection rule $B - L = 2$. Putting this in the formula for $R$, we see clearly that R-parity remains exact even after symmetry breaking. On the other hand, when $16$ is employed, $B - L$ is broken by the $\nu^c$ component which has $B - L = 1$. As a result R-parity is broken after symmetry breaking. To see some explicit examples, note that with $16_H$, one can write renormalizable operators in the superpotential of the form $\Psi\Psi H H$ which after $\langle \nu^c \rangle \neq 0$ leads to R-parity breaking terms of the form $L H u$ discussed in the sec.1. When one goes to the nonrenormalizable operators many other examples arise: e.g. $\Psi\Psi\Psi\Psi H H / M_{Pl}$ after symmetry breaking lead to $QLd^c, LLe^c$ as well as $u^c d^c d^c$ type terms.

4.4 Doublet-triplet splitting (D-T-S):

As we noted in sec.3, splitting the weak doublets from the color triplets appearing in the same multiplet of the GUT group is a very generic problem of all grand unification theories. Since in the SO(10) models, the fermion masses are sensitive to the GUT multiplets which lead to the low energy doublets, the problem of D-T-S acquires an added complexity. What we mean is the following: as noted earlier, if there are only $10$ Higgses giving fermion masses, then we have the bad relation $m_e/m_\mu = m_d/m_s$ that contradicts observations. One way to cure this is to have either an $126$ which leaves a doublet from it in the low energy MSSM in conjunction with the doublet from the $10$'s or to have only $10$'s and have non-renormalizable operators give an effective operator which transforms like $126$. This means that the process of doublet triplet splitting must be done in a way that accomplishes this goal.

One of the simplest ways to implement D-T-S is to employ the missing vev mechanism where one takes two $10$'s (denoted by $H_{1,2}$) and couple them to the $45$ as $AH_1 H_2$. If one then gives vev to $A$ as $\langle A \rangle = i\tau_2 \times diag(a, a, a, 0, 0)$, then it is easy to verify that the doublets (four of them) remain light. This model without further ado does not lead to MSSM. So one must somehow make two of the four doublets heavy. This was discussed in great detail by Babu and Barr. A second problem also tackled by Babu and Barr is the question that once the SO(10) model is made realistic by the addition of say $16 + \bar{16}$, then new couplings of the form $16\cdot\bar{16}\cdot45$ exist in the theory that give nonzero entries at the missing vev position thus destroying the whole suggestion. There are however solutions to this problem by increasing the number of $45$'s.
Another more practical problem with this method is the following. As mentioned before, the low energy doublets in this method are coming from $10$’s only and is problematic for fermion mass relations. This problem was tackled in two papers. In the first paper, it was shown how one can mix in a doublet from the $126$ so that the bad fermion mass relation can be corrected. To show the bare essentials of this techniques, let consider a model with a single $H$, single pair $\Delta + \bar{\Delta}$ and a $A$ and $S \equiv 54$ and write the following superpotential:

$$W = M\Delta\bar{\Delta} + A\Delta^2 \bar{\Delta} + SH^2 + M' H^2$$  \hspace{1cm} (107)$$

After symmetry breaking this leads to a matrix of the following form among the three pairs of weak doublets in the theory i.e. $H_{u,10}, H_{u,\Delta}, H_{u,\bar{\Delta}}$ and the corresponding $H_d$’s. In the basis where the column is given by$(10, 126, \bar{126})$ and similarly for the row, we have the Doublet matrix:

$$M_D = \begin{pmatrix} 0 & <A>/M & 0 \\ <A>/M & 0 & M \\ 0 & M & 0 \end{pmatrix}$$ \hspace{1cm} (108)$$

where the direct $H_{u,10}H_{d,10}$ mass term is fine tuned to zero. This kind of a three by three mass matrix leaves the low energy doublets to have components from both the $10$ and $126$ and thus avoid the mass relations. It is easy to check that the triplet mass matrix in this case makes all of them heavy.

There is another way to achieve the similar result without resorting to fine tuning as we did here by using $16$ Higgses. Suppose there are two $10$’s, one pair of $16$ and $\bar{16}$ (denoted by $\Psi_H, \bar{\Psi}_H$). Let us write the following superpotential:

$$W_{bm} = \Psi_H \bar{\Psi}_H H_1 + \bar{\Psi}_H \Psi_H H_2 + AH_1 H_2 + \Psi_2 \bar{\Psi}_2 AA'H_2$$  \hspace{1cm} (109)$$

If we now give vev’s to $<\nu^c> \neq 0$ and $<\bar{\nu}^c> \neq 0$, then the three by three doublet matrix involving the $H_u$’s from $H_i$ and $\bar{\Psi}_H$ and $H_d$’s from the $H_i$’s and $\Psi_H$ form the three by three matrix which has the same as in the above equation. As a result, the light MSSM doublets are admixtures of doublets from $10$’s and $16$’s. This in conjunction with the last term in the above superpotential gives precisely the GJ mass matrices without effecting the form of the up quark mass matrix.

Thus it is possible to have D-T-S along with phenomenologically viable mass matrices for fermions.
4.5 Final comments on SO(10)

The SO(10) model clearly has a number of attractive properties over the SU(5) model e.g. the possibility to have automatic R-parity conservation, small nonzero neutrino masses, interesting fermion mass relations etc. There is another aspect of the model that makes it attractive from the cosmological point of view. This has to do with a simple mechanism for baryogenesis. It was suggested by Fukugita and Yanagida\textsuperscript{65} that in the SO(10) type models, one could first generate a lepton asymmetry at a scale of about $10^{11}$ GeV or so when the righthanded Majorana neutrinos have mass and generate the desired lepton asymmetry via their decay. This lepton asymmetry in the presence of sphaleron processes can be converted to baryons. This model has been studied quantitatively in many papers and found to provide a good explanation of the observed $n_B/n$\textsuperscript{66}.

5 Other grand unification groups

While the SU(5) and SO(10) are the two simplest grand unification groups, other interesting unification models motivated for different reasons are those based on $E_6$, $SU(6)$, $SU(5) \times U(1)$ and $SU(5) \times SU(5)$. We discuss them very briefly in this final section of the lectures.

5.1 $E_6$ grand unification

These unification models were considered\textsuperscript{67} in the late seventies and their popularity increased in the late eighties after it was demonstrated that the Calabi-Yau compactification of the superstring models lead to the gauge group $E_6$ in the visible sector and predict the representations for the matter and Higgs multiplets that can be used to build realistic models\textsuperscript{68}.

To start the discussion of $E_6$ model building, let us first note that $E_6$ contains the subgroups (i) $SO(10) \times U(1)$; (ii) $SU(3)_L \times SU(3)_R \times SU(3)_c$ and (iii) $SU(6) \times SU(2)$. The $[SU(3)]^3$ subgroup shows that the $E_6$ unification is also left right symmetric. The basic representation of the $E_6$ group is 27 dimensional and for model building purposes it is useful to give its decomposition interms of the first two subgroups:

$$SO(10) \times U(1) \::\: 27 = 16_1 + 10_{-2} + 1_4$$

$$[SU(3)]^3 \::\: 27 = (3, 1, 3) + (1, 3, 3) + (3, 3, 1)$$

47
The fermion assignment can be given in the $[SU(3)]^3$ basis as follows:

\[
(3, 1, 3) = \begin{pmatrix} u \\ d \\ D \end{pmatrix}; \quad (1, 3, \bar{3}) = \begin{pmatrix} u^c \\ d^c \\ D^c \end{pmatrix}; \quad (\bar{3}, 3, 1) = \begin{pmatrix} H_1^0 \\ H_2^+ \\ e^+ \\ H_3^0 \\ \nu^c \\ e^- \end{pmatrix};
\]

We see that there are eleven extra fermion fields than the SO(10) model. Thus the model is non minimal in the matter sector. Important to note that all the new fermions are vector like. This is important from the low energy point of view since the present electroweak data \[i.e. \text{the precision measurement of radiative parameters S, T and U put severe restrictions on extra fermions only if they are not vectorlike. Also the vectorlike nature of the new fermions keeps the anomaly cancellation of the standard model.}\]

Turning now to symmetry breaking, we will consider two interesting chains—although $E_6$ being a group of rank six, there are many possible ways to arrive at the standard model. One chain is:

\[
E_6 \rightarrow [SU(3)]^3 \rightarrow G_{2213} \rightarrow G_{STD}
\]

The first stage of the breaking can be achieved by a $650$ dimensional Higgs field which is the lowest dimension representation that has a singlet under this group. In the case of string models this stage is generally achieved by the Wilson loops involving the gauge fields along the compactified direction. The second stage is achieved by means of the $n_0$ field in the $27$ dimensional Higgs boson. The final stage can be achieved in one of two ways depending on whether one wants to maintain the R-parity symmetry after symmetry breaking. If one does not care about breaking R-parity, the $\nu^c$ field in $27$-Higgs can be used to arrive at the standard model On the other hand if one wants to keep R-parity conserved, the smallest dimensional Higgs field would be $351'$ is needed to arrive at the standard model.

Another interesting chain of symmetry breaking is:

\[
E_6 \rightarrow SO(10) \times U(1) \rightarrow G_{2213} \rightarrow G_{STD}
\]

The first stage of this chain is achieved by a $78$ dim. rep. and the rest can be achieved by the $27$ Higgs as in the previous case.

The fermion masses in this model arise from $27$ higgs since $27_m 27_m 27_H$ is $E_6$ invariant and it contains the MSSM doublets (the $H_i$ fields in the $27$
given above. The $[27]^3$ interaction in terms of the components can be written as

\[
[27]^3 \rightarrow QQD + Q^cQ^cD^c + QQ^cH + LL^cH + R^2n_0 + DD^cn_0 + QLD^c + Q^cL^cD
\]  

(114)

Form this we see that in addition to the usual assignments of B-L to known fermions, if we assign $B - L$ for D as $-2/3$ and $D^c$ as $+2/3$, then all the above terms conserve R-parity prior to symmetry breaking. However when $\langle \nu^c \rangle \neq 0$, a D mix leading to breakdown of R-parity. They can for instance generate a $u^c d^c d^c$ term with strength $\langle \nu^c \rangle \langle n_0 \rangle$. This can lead to the $\Delta B = 2$ processes such as neutron-antineutron oscillation.

5.2 $SU(5) \times SU(5)$ unification

The $SU(5) \times SU(5)$ model that we will discuss here was motivated by the goal of maintaining automatic R-parity conservation as well as the simple see-saw mechanism for neutrino masses in the context of superstring compactification. The reason was the failure of the string models at any level to yield the 126 dim. rep. in the case of SO(10) yielding fermionic compactifications. Although no work has been done on higher level string compactifications with $SU(5) \times SU(5)$ as the GUT group, the model described here involves simple enough representations that it may not be unrealistic to expect them to come out of a consistent compactification scheme. In any case for pure $SU(5)$ at level II all representations used here come out. Let us now see some details of the model.

The matter fields in this case belong to left-right symmetric representations such as $(\bar{5}, 1) + (1, 5) + (10, 1) + (1, \bar{10})$ as follows: (denoted by $F_L, F_R, T_L, T_R$).

\[
F_L = \begin{pmatrix} D_1^c \\ D_2^c \\ D_3^c \\ e^- \\ \nu \end{pmatrix}; F_R = \begin{pmatrix} D_1 \\ D_2 \\ D_3 \\ e^+ \\ \nu^c \end{pmatrix}
\]  

(115)

\[
T_L = \begin{pmatrix} 0 & U^c_3 & u_1 & d_1 \\ 0 & U^c_2 & u_2 & d_2 \\ 0 & U^c_1 & u_3 & d_3 \\ 0 & E^+ & 0 & 0 \end{pmatrix};
\]
This left-right symmetric fermion assignment was first considered in Ref. 70. But the R-parity conserving version of the model was considered in Ref. 71. Crucial to R-parity conservation is the nature of the Higgs multiplets in the theory. We choose the higgses belonging to \((5, \bar{5}), (15, 1) + (1, 15)\). The \(SU(5)\times SU(5)\) group is first broken down to \(SU(3)_c \times SU(2)_L \times SU(2)_R \times U(1)_{B-L}\) by the \((5, \bar{5})\) acquiring vev’s along Diag\((a, a, a, 0, 0)\). This also makes the new vectorlike particles \(U, D, E\) superheavy. The left-right group is then broken down to the \(G_{STD}\) by the \(15\)-dimensional Higgs acquiring a vev in its right handed multiplet along the \(\nu^c\) direction. This component has \(B - L = 2\) and therefore R-parity remains an exact symmetry. The light fermion masses and the electroweak symmetry breaking arise via the vev of a second \((5, \bar{5})\) multiplet acquiring vev along the direction Diag\((0, 0, 0, b, b)\).

A new feature of these models is that due to the presence of new fermions, the normalization of the hypercharge and color are different from the standard \(SU(5)\) or \(SO(10)\) unification models. In fact in this case, \(I_Y = \sqrt{3}\)\((Y/2)\) and as result, at the GUT scale \(\sin^2 \theta_W = \frac{3}{16}\). The GUT scale in this case is therefore much lower than the standard scenarios discussed prior to this.

5.3 Flipped \(SU(5)\)

This model was suggested in Ref. 72 and have been extensively studied as a model that emerges from string compactification. It is based on the gauge group \(SU(5) \times U(1)\) and as such is not a strict grand unification model. Nevertheless it has several interesting features that we mention here.

The matter fields are assigned to representations \(5_{-3}\) (F), \(1_{+5}\) (S) and \(10_{+1}\) (T). The detailed particle assignments are as follows:

\[
F = \begin{pmatrix} u^c_1 \\ u^c_2 \\ u^c_3 \\ e^- \\ \nu \end{pmatrix};
T = \begin{pmatrix} 0 & d_1^c & u_1 & d_1 \\ d_1 & 0 & u_2 & d_2 \\ 0 & u_3 & d_3 & \nu \\ 0 & 0 & 0 & 0 \end{pmatrix};
S = e^+ \tag{116}
\]
The electric charge formula for this group is given by:

\[ Q = I_{3L} - \frac{1}{\sqrt{15}} \lambda_{24} + \frac{1}{5} X \]  \hspace{1cm} (117)

where \( \lambda_a \) (\( a = 1 \ldots 24 \)) denote the SU(5) generators and \( X \) is the \( U(1) \) generator with \( I_{3L} \equiv \lambda_3 \). The Higgs fields are assigned to representations \( \Sigma(10_+1) + \bar{\Sigma} \) and \( H(5_{-2}) + \bar{H} \). The first stage of the symmetry breaking in this model is accomplished by \( \Sigma_{45} \neq 0 \). This leaves the standard model group as the unbroken group. Another point is that since the \( \Sigma_{45} \) has \( B-L = 1 \), this model breaks R-parity (via the nonrenormalizable interactions). \( H \) and \( \bar{H} \) contain the MSSM doublets. An interesting point about the model is the natural way in which doublet-triplet splitting occurs. To see this note the most general superpotential for the model involving the Higgs fields:

\[ W_5 = \epsilon_{abcde} \Sigma^{abc} \Sigma^{cde} H^e + \epsilon_{abcde} \bar{\Sigma}^{abc} \bar{\Sigma}^{cde} \bar{H}_e \]  \hspace{1cm} (118)

On setting \( \Sigma_{45} = M_U \), the first term gives \( \epsilon_{ijk} \Sigma^{ijk} H^k \) which therefore pairs up the triplet in \( H \) with the triplet in \( 10 \) to make it superheavy and since there is no color singlet weak doublet in \( 10 \), the doublet remains light. This provides a neat realization of the missing partner mechanism for D-T-S.

The fermion masses in this model are generated by the following superpotential:

\[ W_F = h_d TTH + h_u T\bar{\Sigma} \bar{H} + h_e \bar{F} HS \]  \hspace{1cm} (119)

It is clear that this model has no \( b - \tau \) mass unification; thus we lose one very successful prediction of the SUSY GUTs. There is also no simple see-saw mechanism. And furthermore the model does not conserve R-parity automatically as already noted. For instance there are higher dim. terms of the form \( TT\Sigma F/M_{Pl} \), \( FF\Sigma S/M_{Pl} \) that after symmetry breaking lead to R-parity breaking terms like \( QLd^c \) and \( LLe^c \). Thus they erase the baryon asymmetry in the model.

5.4 **SU(6) GUT and naturally light MSSM doublets:**

In this section, we discuss an SU(6) GUT model which has the novel feature that under certain assumptions the MSSM Higgs doublets arise as pseudo-Goldstone multiplets in the process of symmetry breaking without any need for fine tuning. This idea was suggested by Berezhiani and Dvali and has been pursued in several subsequent papers.
We will only discuss the Higgs sector of the model since our primary goal is to illustrate the new mechanism to understand the D-T-S. Consider the Higgs fields belonging to the $35$ (denoted by $\Sigma$), and to $6$ and $\bar{6}$ (denoted by $H, \bar{H}$ respectively). Then demand that the superpotential of the model has the following structure:

$$W = W_{\Sigma} + W(H, \bar{H})$$

(120)

i.e. set terms such as $H\Sigma\bar{H}$ to zero. This is a rather adhoc assumption but it has very interesting consequences. Let the fields have the following pattern of vev’s.

$$
\begin{pmatrix}
1 \\
0 \\
0 \\
0 \\
0
\end{pmatrix}
$$

(121)

\[ <\Sigma> = \text{Diag}(1,1,1,-2,-2) \]

Note that $\Sigma$ breaks the $SU(6)$ group down to $SU(4) \times SU(2) \times U(1)$ whereas $H$ field breaks the group down to $SU(5) \times U(1)$. Note that the Goldstone bosons for the breaking to $SU(5) \times U(1)$ are in $5 + \bar{5} + 1$ i.e. under the standard model group they transform as: $(SU(3) \times SU(2) \times U(1))$

$$GB's = (3,1) + (1,2) + (\bar{3},1) + (1,2) + (1,1)$$

(122)

whereas the Goldstone bosons generated by the breaking of $SU(6) \to SU(4) \times SU(2) \times U(1)$ by the $\Sigma$ are:

$$\bar{3},2 + (3,2) + (1,2) + (1,2)$$

(123)

Since both the vev’s break $SU(6) \to SU(3) \times SU(2) \times U(1)$, the massless states that are eaten up in the process of Higgs mechanism are

$$(3,1) + (\bar{3},1) + (1,2) + (1,2) + (3,2) + (\bar{3},2) + (1,1)$$

(124)

We then see that the only Goldstones that are not eaten up are the two weak doublets $(1,2) + (1,2)$. These can be identified with the MSSM doublets. This model can be made realistic by adding matter fermions to two $\bar{6}$’s and a $15$ per generation to make the model anomaly free. We do not discuss this here.
6 Epilogue

This set of lectures is meant to be a pedagogical overview of the vast (and still expanding) field of supersymmetric grand unification. The body of literature in this field is large and only a very selective sample has been given. They should be consulted for additional references.

While this is a very interesting field, it is by no means clear that a simple GUT group is the only way to achieve unification of particles and forces in the universe. It could for instance be that at the string scale, in superstring theories, the standard model or an extended version of it with extra U(1)’s emerges directly. This possibility has certain advantages and distinct signatures. For instance, one need not worry about questions such as doublet-triplet splitting in such models and there would be no need for proton to decay. There is however a puzzle with this scenario—i.e. the MSSM spectrum leads to unification around $10^{16}$ GeV whereas the string scale is around $10^{17.6}$ GeV or so. How does one understand this gap. It could be that there are intermediate scales or new particles that change the running of couplings that close this gap. A more intriguing suggestion recently put forward by Horava and Witten is that the existence of an 11th dimension with an appropriate compactification along it might change the running of the gravitational coupling from naive $G_N E^2$ to $G_N E^3 (R_{11})$ (where $R_{11}$ is the compactification radius of the 11th dimension) in such a way that it might bring all couplings to unify at the same $10^{16}$ GeV scale.

In the early days of grand unification, it used to be thought that in addition to the attractive property of unification of couplings, the GUT models are needed for an understanding of electric charge quantization and the origin of matter of in the universe. It is now known that one can understand the electric charge quantization using only cancellation of gauge anomalies; moreover, while GUT models lead to quantization of electric charge, to obtain observed values of these charges, an extra assumption regarding the Higgs representations is needed. Thus understanding the values of the electric charges of elementary fermions needs more than a simple GUT group.

On the cosmological side, the advent of the idea of weak scale baryogenesis has largely overshadowed the significance of grand unification in understanding the baryon asymmetry of nature. Thus ultimately, the unification of coupling constants may be the only (though very attractive) motivation for grand unification. This paragraph is meant to convey the sentiment that grand unification should not be considered a panacea for all the woes of the standard model but as an interesting approach to a more elegant extension.

On more phenomenological level, tests of the grand unification idea are
always quite model dependent; if any of them show up, we will know that the idea may be operative whereas if no experimental signal appears, it will not necessarily rule out the idea or make it any less plausible. An analogy may be made with the corresponding situation in supersymmetry. Most people believe that if the standard model Higgs boson with a mass less than 150 GeV does not show up at the LHC or some other high energy machine, interest in supersymmetry as an idea relevant for physics will lessen considerably. There is no such stringent test for SUSY GUTs. On the other hand, observation of significant flavor violation as in $\mu \rightarrow e + \gamma$ or $p \rightarrow K^+ \nu_{\mu}$ or $N \rightarrow \bar{N}$ oscillation will signal some form of grand unification. There will then be an urgency to focus on particular GUT models and to solve the various problems associated with them.

On the theoretical side, understanding the fermion mass and mixing hierarchies may or may not suggest SUSY GUT. While SUSY GUTs provide one class of models for this discussion, the fermion mass problem could also be addressed within the framework of radiative corrections as in the examples discussed in Ref. The recent indications of neutrino masses from various experiments such as the solar and atmospheric neutrino experiments, if they are confirmed, will certainly be strong indications of a local B-L symmetry as well as left-right symmetric grand unification and a scale of these new symmetries most likely in the $10^{11}$ Gev range.

Finally, the interplay between the hidden sector and the SUSY GUT of flavor is an interesting venue for research. Could complex structures for the hidden and the messenger sectors be maintained without sacrificing unification of couplings. What is the role of superstring theories in dictating the hidden sector? Is it the hidden sector gluino condensate that plays the role of the Polonyi singlet or is it different as in the anomalous U(1) models? SUSY GUTs with anomalous U(1) remains essentially unexplored and more work is needed to unravel its full ramifications.

The field clearly has immense possibilities and hopefully this review will provide a summary of the relevant basic ideas that a beginner could use to make effective contributions which are so badly needed in so many areas.

I would like to thank Jon Bagger and K. T. Mahanthappa for kind invitation to present these lectures at TASI97 and warm hospitality in a pleasant Boulder summer, the students for their responses and comments and many colleagues for sharing their insight and enthusiasm into various aspects of supersymmetric grand unification. In particular, I wish to thank K. S. Babu, Z. Berezhiani, B. Brahmachari, Z. Chacko, B. Dutta, R. Kuchimanchi, S. Nandi, M. K. Parida, J. C. Pati, A. Rasin, A. Riotto, G. Senjanović for discussions over the years on many of the topics discussed here. This work has been...
supported by the National Science Foundation grant no. PHY-9421386.
