Abstract
Let $K \subset S^3$ be a hyperbolic fibered knot such that $S^3_{p/q}(K)$, the $\frac{p}{q}$–surgery on $K$, is either reducible or an atoroidal Seifert fibered space. We prove that if the monodromy of $K$ is right-veering, then $0 \leq \frac{p}{q} \leq 4g(K)$. The upper bound $4g(K)$ cannot be attained if $K$ is an L-space knot. If the monodromy of $K$ is neither right-veering nor left-veering, then $|q| = 1$ and the surgery is irreducible.

As a corollary, for any given positive torus knot $T$, if $p/q \geq 4g(T) + 4$, then $p/q$ is a characterizing slope. This improves earlier bounds of Ni–Zhang and McCoy. We also prove that some finite/cyclic slopes are characterizing. More precisely, 14 is characterizing for $T_{4,3}$, 17 is characterizing for $T_{5,3}$, and $4n + 1$ is characterizing for $T_{2n+1,2}$ except when $n = 5$. By a recent theorem of Tange, this shows that $T_{2n+1,2}$ is the only knot in $S^3$ admitting a lens space surgery while the Alexander polynomial has the form $t^n - t^{n-1} + t^{n-2} + \cdots$.

In the appendix, we prove that if the rank of the second term of the knot Floer homology of a fibered knot is 1, then the monodromy is either right-veering or left-veering.

1 Introduction
Given a knot $K \subset S^3$, let $S^3_{p/q}(K)$ be the manifold obtained by $\frac{p}{q}$–surgery on $K$. The main theorem in this paper gives a constraint on Seifert fibered surgeries on hyperbolic fibered knots.

Theorem 1.1. Let $K \subset S^3$ be a hyperbolic fibered knot such that $S^3_{p/q}(K)$ is either reducible or an atoroidal Seifert fibered space.
(1) If the monodromy of $K$ is right-veering, then $0 \leq \frac{p}{q} \leq 4g(K)$. If $K$ is also an L-space knot, then $\frac{p}{q} \neq 4g(K)$.
(2) If the monodromy of $K$ is neither right-veering nor left-veering, then $|q| = 1$ and $S^3_{p/q}(K)$ is irreducible.
Remark 1.2. If a hyperbolic knot \( K \subset S^3 \) admits a reducible surgery, then the surgery slope is an integer \( p \) with \( 2 \leq |p| \leq 2g(K) - 1 \) [20, 21, 29].

Recall that a three-manifold \( Y \) is atoroidal if it does not contain an incompressible torus. Some authors use the term “atoroidal” to mean that \( \pi_1(Y) \) does not contain a \( \mathbb{Z}^2 \) subgroup, which is not the assumption we want.

Right-veering diffeomorphisms were defined in [25]. (This concept was originally conceived by Gabai.) Let \( F \) be a compact oriented surface with boundary, \( a, b \subset F \) be two properly embedded arcs with \( a(0) = b(0) = x \in \partial F \). We isotope \( a, b \) with endpoints fixed, so that \( |a \cap b| \) is minimal. We say \( b \) is to the right of \( a \) at \( x \), if either \( b \) is isotopic to \( a \) with endpoints fixed, or \((b \cap U) \setminus \{x\}\) lies in the “right” component of \( U \setminus a \), where \( U \subset F \) is a small neighborhood of \( x \). See Figure 1. A diffeomorphism \( \phi: F \to F \) with \( \phi|_{\partial F} = \text{id} \) is right-veering if for every \( x \in \partial F \) and every properly embedded arc \( a \subset F \) with \( x \in a \), the image \( \phi(a) \) is to the right of \( a \) at \( x \). Similarly, we can define left-veering diffeomorphisms.

![Figure 1: The arc b is to the right of a at x.](image)

A rational homology sphere \( Y \) is an \( L \)-space if \( \text{rank} \hat{HF}(Y) = |H_1(Y)| \). A knot \( K \subset S^3 \) is an \( L \)-space knot, if there exists a slope \( \frac{p}{q} > 0 \) such that \( S^3_{\frac{p}{q}}(K) \) is an \( L \)-space.

Remark 1.3. Theorem 1.1 was more or less known to experts. The point we want to make is that this theorem becomes very useful when combined with Heegaard Floer homology. First of all, knot Floer homology detects whether a knot is fibered [19, 33]. Secondly, the right-veering condition can often be checked using Heegaard Floer homology. Honda–Kazez–Matić [25] proved that if an open book supports a tight contact structure, then the corresponding monodromy is right-veering. It is often possible to get tightness from Heegaard Floer homology [40]. For example, when \( K \) is an \( L \)-space knot, then \( K \) is fibered, and the open book with binding \( K \) supports the unique tight contact structure on \( S^3 \), thus the monodromy of \( K \) is right-veering. In the appendix, we will prove that if \( \text{rank} \hat{HF}(K)(S^3, g(K) - 1) = 1 \) for a fibered knot \( K \), then its monodromy is either right-veering or left-veering.

Theorem 1.1 can be used to get bounds on characterizing slopes for torus knots. A slope \( \frac{p}{q} \in \mathbb{Q} \) is a characterizing slope for a knot \( L \subset S^3 \), if \( S^3_{\frac{p}{q}}(K) \cong S^3_{\frac{p}{q}}(L) \) implies \( K = L \), where “\( \cong \)” stands for orientation-preserving homeomorphism. A famous theorem of Kronheimer–Mrowka–Ozsváth–Szabó [27] says that all rational numbers are characterizing slopes for the unknot, confirming a
conjecture of Gordon. Special cases of this theorem were proved in \cite{12, 14, 21}, and a Heegaard Floer proof of this theorem was given in \cite{41}. Ozsváth and Szabó \cite{42} further proved that all rational numbers are characterizing slopes for the trefoils and the figure-8 knot. These knots are the only knots for which the sets of characterizing slopes are known.

Dehn surgeries on torus knots have been classified in \cite{32}. For the torus knot $T_{r,s}$, $r, s > 0$, the $\frac{r}{s}$–surgery is a connected sum of two lens spaces. If $\frac{p}{q} = rs \pm \frac{1}{r}$, the $\frac{p}{q}$–surgery will be the lens space $L(p, qs^2)$, where the convention for $L(p, q)$ is that it is oriented as the $\frac{p}{q}$–surgery on the unknot. For all other slopes, the $\frac{p}{q}$–surgery is a Seifert fibered space over $S^2(r, s, |ps - qr|)$.

Ni and Zhang \cite{34} proved that $\frac{p}{q}$ is characterizing for the torus knot $T_{r,s}$ whenever $\frac{p}{q} > \frac{30(r^2 - 1)(s^2 - 1)}{67}$, where $r, s > 0$. McCoy \cite{30} improved this lower bound to $\frac{43}{4}(rs - r - s)$ which is linear in terms of the genus. As a corollary of Theorem 1.1, we improve the lower bound.

**Corollary 1.4.** Let $r, s > 0$ be a pair of relatively prime integers. Then a slope $\frac{p}{q}$ is characterizing for the torus knot $T_{r,s}$ whenever

$$\frac{p}{q} \geq 4g(T_{r,s}) + 4 = 2(r - 1)(s - 1) + 4.$$ 

Note that Corollary 1.4 contains one previous unknown case of finite surgery: the 13–surgery on $T_{5,2}$, which is an I–type spherical manifold.

**Remark 1.5.** The bound $4g(T_{r,s}) + 4$ comes from a theorem of McCoy \cite{30} Theorem 1.1], which says $g(K) = g(T_{r,s})$ if $S^3_{p/q}(K) \cong S^3_{p/q}(T_{r,s})$ and $\frac{p}{q} \geq 4g(T_{r,s}) + 4$. As mentioned in \cite{30} Remark 3.9], it is possible to lower the bound $4g(T_{r,s}) + 4$. Thus it is conceivable to lower the bound in Corollary 1.4 to $4g(T_{r,s})$. However, this cannot hold for all torus knots, since $S^3_{21}(T_{5,4}) \cong S^3_{21}(T_{11,2})$ \cite{31} Example 1.1], and $21 = 4g(T_{11,2}) + 1$. So we will not seek a sharper bound for simplicity. Instead, we will focus on the surgeries with finite $\pi_1$ not covered by Corollary 1.4.

**Corollary 1.6.** The slope 14 is a characterizing slope for $T_{4,3}$, and the slope 17 is a characterizing slope for $T_{5,3}$.

A particularly interesting case is $s = 2, r = 2n + 1$, where $n = g(T_{r,2})$. The slopes $4n + t$, $t = 0, 1, 2, 3, 4$, are special. The $(4n + 2)$–surgery is reducible. The $(4n + 1)$ and $(4n + 3)$–surgeries are lens spaces $L(4n + 1, 4)$ and $L(4n + 3, 4)$. The $4n$ and $(4n + 4)$–surgeries are prism manifolds. It follows from a theorem of Greene \cite{23} that $4n + 2$ is characterizing. Baker \cite{1} proved that if $S^3_p(K)$ is a lens space with $p \geq 4g(K) - 1$, then $K$ is a doubly primitive knot. Building on Baker’s work, Rasmussen \cite{14} showed that $4n + 3$ is characterizing. The fact that $4n$ and $4n + 4$ are characterizing slopes was proved by Ni–Zhang \cite{35}.

Greene \cite{22} proved that the list of doubly primitive knots given by Berge \cite{3} is complete. Combined with Baker’s work, one can answer the question whether $4n + 1$ is a characterizing slope for $T_{2n+1,2}$, but the author did not find such
statement in the literature. In this paper, we will provide an answer to this question without using Baker’s work.

**Theorem 1.7.** If the \((4n+1)\)-surgery on a knot \(K \subset S^3\) is \(L(4n+1,4)\), then either \(K = T_{2n+1,2}\) or \(n = 5\) and \(K\) has the same knot Floer homology as \(T_{5,4}\).

Using a recent result of Tange [45], we also get the following characterization of \(T_{2n+1,2}\) among all knots with lens space surgeries.

**Corollary 1.8.** If a knot \(K \subset S^3\) admits a positive lens space surgery and

\[
\Delta_K(t) = t^n - t^{n-1} + t^{n-2} + \cdots ,
\]

then \(K = T_{2n+1,2}\).

**Proof.** Suppose that the \(p\)-surgery on \(K\) is a lens space \(L(p,q)\). By [45], \(L(p,q)\) is also the \(p\)-surgery on \(T_{2n+1,2}\). Our conclusion follows from Theorem 1.7 and [44].

This paper is organized as follows. In Section 2, we briefly recall some results about essential laminations and changemaker lattices. In Section 3, we prove Theorem 1.1 using essential laminations. Corollaries 1.4 and 1.6 are also proved. In Section 4, we prove Theorem 1.7 using Greene’s theory of changemaker lattices. In the appendix, we prove Theorem A.1 which says that if the second term of the knot Floer homology of a fibered knot has rank 1, then the monodromy is either right-veering or left-veering.

**Acknowledgements.** The author was partially supported by NSF grant numbers DMS-1252992 and DMS-1811900. The author wishes to thank David Gabai for commenting on an earlier draft of this paper, and referring the author to lots of work on laminations.

## 2 Preliminaries

In this section, we will collect some results about essential laminations and changemaker lattices we will use.

### 2.1 Essential laminations

Essential laminations were introduced by Gabai and Oertel [18] as a generalization of incompressible surfaces. There are two special classes of essential laminations: very full laminations (defined by Gabai and Mosher, see [10]) and genuine laminations [17]. We will not give the definitions here. Instead, we will list the necessary results.

The first result is in Gabai and Oertel’s original paper [18, Theorem 6.1].

**Theorem 2.1** (Gabai–Oertel). *If a closed oriented 3–manifold \(Y\) contains an essential lamination, then the universal cover of \(Y\) is \(\mathbb{R}^3\).*
The next theorem is due to Brittenham and Claus [11]. For the first part, see [7, Corollary 4] and the paragraph after it. The second part was explicitly stated in [3] Section 1].

**Theorem 2.2** (Brittenham, Claus). *If a Seifert fibered space with base orbifold \( S^2(a, b, c) \) contains an essential lamination, then it also contains a taut foliation. Moreover, this manifold does not contain any genuine lamination.*

Let \( K \subset S^3 \) be a hyperbolic knot. If \( \lambda \) is a very full lamination in the knot complement, one can define the *degeneracy locus* \( d(\lambda) \) which is in the form \( \frac{m}{n} \). Here \( m, n \) are integers which are not necessarily relatively prime, \((m, n) \neq (0, 0)\). Gabai and Mosher proved that any hyperbolic knot complement contains a very full lamination.

When \( K \) is fibered, the stable lamination transverse to the fibration is very full. In this case, \( \frac{1}{d(\lambda)} \in \mathbb{Q} \) is also known as the *fractional Dehn twist coefficient* of the monodromy [24]. The following proposition can be found in [25, Proposition 3.1].

**Proposition 2.3** (Honda–Kazez–Matić). *If \( K \) is a hyperbolic fibered knot, then the monodromy of \( K \) is right-veering if and only if \( \frac{1}{d(\lambda)} > 0 \).

As a result, the monodromy of \( K \) is left-veering if and only if \( \frac{1}{d(\lambda)} < 0 \). If the monodromy is neither right-veering nor left-veering, then \( d(\lambda) = \frac{m}{n} \).

The following theorem was due to Gabai [16, Theorem 8.8].

**Theorem 2.4** (Gabai). *Let \( K \subset S^3 \) be a hyperbolic knot, \( \lambda \) be a very full lamination in its complement, then the degeneracy locus \( d(\lambda) \) is either \( \frac{m}{n} \) or \( \frac{m}{1} \) for an integer \( m \) with \( |m| \leq 4g(K) - 2 \). If \( K \) is fibered and \( \lambda \) is the stable lamination transverse to the fibration, then \( |m| \geq 2 \).

If \( \frac{p}{q} \) is a slope, and \( d(\lambda) = \frac{m}{n} \), define \( \Delta(d(\lambda), \frac{p}{q}) = |pn - gm| \). The first part of the following theorem can be found in [18] Theorem 5.3], and the same proof yields the second part. Gabai was aware of the result about genuine laminations which was explicitly stated by Brittenham [9]. Gabai and Mosher also proved this theorem for any hyperbolic cusped manifolds, see [10, Theorem 6.48].

**Theorem 2.5** (Gabai). *Let \( K \subset S^3 \) be a hyperbolic fibered knot, \( \lambda \) be the stable lamination transverse to the fibration. If \( \Delta(d(\lambda), \frac{p}{q}) \geq 2 \), \( \lambda \) will be an essential lamination in \( S^3_{p/q}(K) \). If \( \Delta(d(\lambda), \frac{p}{q}) \geq 3 \), \( \lambda \) will be a genuine lamination in \( S^3_{p/q}(K) \).*

2.2 Changemaker lattices

In this subsection, we briefly recall the theory of changemaker lattices of Greene [22,23].

When \( Y \) is a rational homology sphere and \( t \in \text{Spin}^c(Y) \), Ozsváth and Szabó [36] defined the *correction term* \( d(Y, t) \in \mathbb{Q} \) which is an invariant of the pair.
Lemma 2.9. The torsion coefficients of \( K \) can be determined by

\[
t_i(K) = \begin{cases} 
\min_{c} \frac{c^2 - n - 1}{8}, & \text{for each } i \in \{0, 1, \ldots, \lfloor \frac{p}{2} \rfloor \}, \\
0, & \text{for } i > \frac{p}{2}.
\end{cases}
\]

where \( c \) is subject to

\[
c \in (1, 1, \ldots, 1) + 2\mathbb{Z}^{n+1}, \quad (c, \sigma) + p \equiv 2i \pmod{2p}.
\]
The coefficients $a_i$ of $\Delta_K$ can be determined by the following rule. For $i > 0$,

$$a_i = t_i - t_{i-1} - 2t_i + t_{i+1},$$

and

$$a_0 = 1 - 2 \sum_{i>0} a_i.$$  

Although the genus of $K$ can be deduced from $\Delta_K$, it is useful to know the following direct formula [23, Proposition 3.1]:

$$2g(K) = p - |\sigma|_1 = p - \sum_{j=0}^n |\sigma_j|.$$  

(2)

3 Seifert fibered surgeries

Now we are ready to prove our main theorem.

Proof of Theorem 1.1. (1) If the monodromy of $K$ is right-veering [25], let $\lambda$ be the stable lamination transverse to the fibration, then the degeneracy locus is positive by Proposition 2.3. So $d(\lambda)$ has the form $\frac{m}{1}$ for a positive integer $m$ with $2 \leq m \leq 4g(K) - 2$ by Theorem 2.4. If $\frac{p}{q} > 4g(K)$ or $\frac{p}{q} < 0$, $\Delta(\frac{p}{q}, \frac{m}{1}) \geq 3$, so Theorem 2.5 implies that $S^3_{p/q}(K)$ contains a genuine lamination. By Theorem 2.1, $S^3_{p/q}(K)$ is irreducible and its $\pi_1$ is infinite.

If $S^3_{p/q}(K)$ is an irreducible atoroidal Seifert fibered space with infinite $\pi_1$, then its base orbifold is $S^2$ with 3 singular points, we get a contradiction by Theorem 2.2.

If $S^3_{p/q}(K)$ is a torus knot, since $\Delta_K = \Delta_{T_{r,s}}$, we must have $K = T_{r,s}$. If $K$ is a satellite knot, let $R \subset S^3 \setminus K$ be an “innermost” incompressible torus. Let $V$ be the solid torus bounded by $R$ in $S^3$, and let $L$ be the core of $V$. Since $S^3_{p/q}(K)$ is irreducible and atoroidal, using [15], $V_{p/q}(K)$ must be a solid torus. In this case, $K$ is a 0–bridge or 1–bridge braid in $V$ with winding number $\theta$.

Proof of Corollary 1.4. When $\frac{p}{q} \geq 4g(T_{r,s}) + 4$ and $S^3_{p/q}(K) \cong S^3_{p/q}(T_{r,s})$, we know that $S^3_{p/q}(T_{r,s})$ is an L-space and $K$ is fibered [13, Proposition 3.1]. By the work of McCoy [30], Theorem 1.1, $\chi(K) = \chi(T_{r,s})$ and $\Delta_K = \Delta_{T_{r,s}}$.

If $K$ is hyperbolic, our result follows from Theorem 1.1.

If $K$ is a torus knot, since $\Delta_K = \Delta_{T_{r,s}}$, we must have $K = T_{r,s}$. If $K$ is a satellite knot, let $R \subset S^3 \setminus K$ be an “innermost” incompressible torus. Let $V$ be the solid torus bounded by $R$ in $S^3$, and let $L$ be the core of $V$. Since $S^3_{p/q}(K)$ is irreducible and atoroidal, using [13], $V_{p/q}(K)$ must be a solid torus. In this case, $K$ is a 0–bridge or 1–bridge braid in $V$ with winding number $\theta$. 

7
Figure 2: A negative definite plumbing diagram of $X$. There are $n-1$ copies of $-2$.

$w > 1$, and gcd$(p, w) = 1$ for homological reasons. The simple loop with slope $p/(qw^2)$ on $R$ is null-homologous in $V_{p/q}(K)$, so $S^3_{p/q}(K) = S^3_{p/(qw^2)}(L)$. Since $R$ is innermost, $L$ is not a satellite knot, so $L$ is either hyperbolic or a torus knot.

If $L$ is hyperbolic, it follows from [28, Theorem 1.2] that $w^2 \leq 8$, so $w = 2$. Hence $K$ is a $(2h+1, 2)$-cable of $L$ and $p/q = 4h+2+1/n$ for some $n \in \mathbb{Z} \setminus \{0\}$. Since $\frac{p}{q} \geq 4g(K) + 4$, we have

$$4h + 2 + \frac{1}{n} \geq 4g(K) + 4 = 4(2g(L) + h) + 4,$$

hence $2 + \frac{1}{n} \geq 8g(L) + 4$, which is not possible.

If $L$ is a torus knot, we can get a contradiction by the same argument as in the proof of [34, Proposition 2.5].

**Proof of Corollary 1.6.** Let $p = 14$ or $17$, and $T$ be $T_{4,3}$ or $T_{5,3}$. It follows from [24] that if $S^3_p(K) \cong S^3_p(T)$, then $\Delta_K = \Delta_T$. See also [35, Known Facts 1.2 (3)]. Hence Theorem 1.1 rules out the possibility that $K$ is hyperbolic. The finite surgeries on satellite knots have been classified in [6, Corollary 1.4] and [4, Theorem 7], thus we can check $K$ cannot be satellite. So $K$ is a torus knot. Since $\Delta_K = \Delta_T$, we must have $K = T$.}

4 The $(4n + 1)$–surgery on $T_{2n+1,2}$

Throughout this section, let $T = T_{2n+1,2}$ and let $K$ be a knot satisfying $S^3_{4n+1}(K) \cong S^3_{4n+1}(T)$.

The following lemma is a small part of Greene’s lens space realization theorem [22]. Since we do not need the full strength of Greene’s theorem, we will give a quick proof here.

**Lemma 4.1.** Either $\Delta_K = \Delta_T$, or $n = 5$ and $\Delta_K = \Delta_{T_{5,4}}$.

**Proof.** We know $Y = S^3_{4n+1}(T) \cong L(4n+1, 4) = -L(4n+1, n)$. (Note that our convention of the orientation of $L(p, q)$ is opposite to the convention in [22].) Since

$$\frac{4n+1}{n} = [5, 2, \ldots, 2]^- := 5 - \frac{1}{2 - \frac{1}{2 - \frac{1}{\ddots - \frac{1}{2}}}},$$

and
where there are \((n - 1)\) copies of 2 in the expression, we conclude that \(Y\) is the boundary of a negatively plumbed 4–manifold \(X\) with plumbing diagram given in Figure \(2\) Since \(X\) is sharp, it follows from Theorem \(2.8\) that the lattice \(\Lambda\) is a changemaker lattice.

Now \(\Lambda\) has a basis consisting of one vector with norm 5 and \((n - 1)\) vectors with norm 2. Any norm 2 vector in \(\mathbb{Z}^{n+1}\) must be of the form \(e_i \pm e_j\), where \(e_0, e_1, \ldots, e_n\) is the usual orthonormal basis. Since \(\Lambda = (\sigma)^\perp\), the two corresponding coordinates of \(\sigma\) must be equal. Thus we conclude that \(n\) coordinates of \(\sigma\) are equal. Since \(\sigma_0 = 1\) (see the proof of \([22, \text{Theorem 1.6}]\)), \(\sigma\) must be of the form

\[
(1, a, a, \ldots, a) \text{ or } (1, 1, 1, \ldots, 1, b)
\]

for some \(a, b \geq 1\). Since \(\Lambda = (\sigma)^\perp\) contains a vector with norm 5, we have \(a = 2\) and \(b \in \{2, 4\}\).

If \(\sigma = (1, 2, 2, \ldots, 2)\), using Lemma \(2.9\) we can get \(\Delta_K = \Delta_T\). (It is easier to see \(g(K) = n\) using \([21]\).)

If \(b = 2\), the norm of \(\sigma\) is \(n + 4\). By Theorem \(2.8\) the norm of \(\sigma\) is \(4n + 1\), so \(n = 1\). This falls into the case we just considered.

If \(b = 4\), the norm of \(\sigma\) is \(n + 16\). Since the norm of \(\sigma\) is \(4n + 1\), \(n = 5\). By the computation in \([36, \text{Section 10.3}]\), \(\Delta_K = \Delta_{T_{5,4}}\).

**Proof of Theorem \(1.7\)** By Lemma \(1.1\) either \(\Delta_K = \Delta_T\), or \(n = 5\) and \(\Delta_K = \Delta_{T_{5,4}}\). In the latter case, \(K\) has the same knot Floer homology as \(T_{5,4}\) by \([39]\).

Now we consider the case \(\Delta_K = \Delta_T\). We have \(g(K) = g(T)\).

If \(K\) is hyperbolic, we get a contradiction by Theorem \(1.1\).

If \(K\) is a torus knot, since \(\Delta_K = \Delta_T\), we get \(K = T\).

If \(K\) is a satellite knot, using the classification of lens space surgeries on satellite knots \([5, 46, 47]\), we see that \(K\) is the \((2uv + 1, 2)\)-cable of \(T_{u,v}\) and \(4n + 1 = 4uv + 1\). Then

\[
g(K) = (u - 1)(v - 1) + uv > uv = n,
\]

a contradiction. \(\square\)

**Appendix: A criterion for veering**

In this appendix, we assume the readers are familiar with the basic notions of knot Floer homology \([37, 42]\). We will prove the following theorem.

**Theorem A.1.** Let \(Y\) be a closed, oriented 3–manifold, \(K \subset Y\) be a fibered knot with fiber \(F\) and monodromy \(\phi\). If

\[
\text{rank}HF_{\phi}(Y, K, [F], g(F) - 1) = 1,
\]

then \(\phi\) is either right-veering or left-veering.
Theorem A.1 easily follows from Baldwin and Vela-Vick’s work [2], which will be introduced below.

Let $K$ be a null-homologous knot in a closed, oriented 3–manifold $Y$, and let $F$ be a Seifert surface. There is a chain map
\[ \partial_z: \CFK(Y, K, [F], i) \to \CFK(Y, K, [F], i - 1) \]
defined by counting holomorphic disks with $n_z = 1$. Similarly, there is a chain map
\[ \partial_w: \CFK(Y, K, [F], i - 1) \to \CFK(Y, K, [F], i). \]

The following theorem is contained in the proof of [2, Theorem 1.1].

**Theorem A.2.** Let $K$ be a fibered knot in a closed, oriented 3–manifold $Y$. Let $F$ be a Seifert surface, and let $\phi: F \to F$ be the monodromy of the corresponding open book. If $\phi$ is not left-veering, then the induced map
\[ (\partial_z)_*: \HF(Y, K, [F], 1 - g(F)) \to \HF(Y, K, [F], -g(F)) \]
is nonzero. Similarly, if $\phi$ is not right-veering, then the induced map
\[ (\partial_w)_*: \HF(Y, K, [F], -g(F)) \to \HF(Y, K, [F], 1 - g(F)) \]
is nonzero.

**Proof of Theorem A.1.** We will use $\mathbb{Q}$–coefficients for Heegaard Floer homology. Assume that $\phi$ is neither right-veering nor left-veering. Let $C = \CFK(Y, K, [F])$ be the $\mathbb{Z}^2$–filtered knot Floer chain complex. By [43, Lemma 4.5], $C$ is filtered chain homotopy equivalent to a chain complex $C'$ with
\[ C'\{i, j\} \cong \HF(Y, K, [F], j - i). \]

Let $a$ be a generator of $C'\{(0, -g(F))\}$, consider the component $b$ of $\partial^2 a$ in $C'\{(-1, -1 - g(F))\}$. On one hand, since $\partial^2 = 0$, $b = 0$. On the other hand, $b$ is just $(\partial_z)_* \circ (\partial_w)_*(a)$. By Theorem A.2, both $(\partial_z)_*$ and $(\partial_w)_*$ are isomorphisms, so $b \neq 0$, a contradiction.

It is well-known that $\HF(Y, K, [F], g(F))$, the topmost term in knot Floer homology, contains a lot of information about the topology of the knot complement [19, 33, 35]. It is natural to ask what topological information is contained in other terms of $\HF(Y, K, [F], g(F))$. Baldwin and Vela-Vick’s work [2] and our Theorem A.1 gave some partial answers to this question.
