Dipole Moments of the Rho Meson

M.B. Hecht, B.H.J. McKellar

School of Physics, University of Melbourne, Parkville VIC 3052, Australia

(January 28, 2022)

Abstract

The electric and magnetic dipole moments of the rho meson are calculated using the propagators and vertices derived from the QCD Dyson-Schwinger equations. Results obtained from using the Bethe-Salpeter amplitude studied by Chappell, Mitchell and Tandy, and Pichowsky and Lee, are compared. The rho meson EDM is generated through the inclusion of a quark electric dipole moment, which is left as a free variable. These results are compared to the perturbative results to obtain a measure of the effects of quark interactions and confinement. The two dipole moments are also calculated using the phenomenological MIT bag model to provide a further basis for comparison.

I. INTRODUCTION

The electric and magnetic dipole moments of the rho meson, the lowest lying vector particle state are calculated using the semi-phenomenological n-point functions of Quantum Chromodynamics (QCD) obtained in the Dyson-Schwinger/Bethe-Salpeter framework. The rho meson is studied to provide some insight into the effect of QCD and confinement on the electromagnetic moments of hadrons, especially the question of the existence of a non-zero EDM for the neutron and the applications this has to the study of CP violation. In practice one is interested in these parameters for the nucleon and other hadrons, where they may be measured. But the study of the rho allows us to obtain insights without venturing into the complications of the three body system in QCD.

The Dyson-Schwinger equations are a series of coupled integral equations relating the n-point functions of QCD to one another. They provide a continuum method of calculation in the strong coupling regime of QCD and as such are able to relate the Greens functions of QCD to hadronic properties. For a review of this topic see [1]. The use of the Dyson-Schwinger and Bethe-Salpeter equations to calculate hadronic properties has been applied to pion observables [2, 3], kaon electromagnetic form factors [3], \( \rho - \omega \) mixing [7] and the anomalous \( \gamma \pi^* \rightarrow \pi \pi \) form factor [8].

This calculation makes use of a model form for the quark propagator which ensures confinement by having no Lehmann representation, preventing free quark production thresholds, \( i.e., \) the quark cannot go “on mass-shell”. A phenomenological form for the rho amplitude, which models the momentum distribution of the quarks inside, and the finite size of, the rho, is used, as well as the Ball-Chiu/Curtis-Pennington quark-photon vertex which ensures that both the Ward-Takahashi Identity and multiplicative renormalizability are preserved. The CP violating electric dipole term is introduced via a quark EDM which is left as a free parameter which can be varied.

Results obtained from using the Bethe-Salpeter amplitude studied by Mitchell and Tandy [7], Chappell [9], and Pichowsky and Lee [10], are compared. Perturbation theory results
[11], which ignore the dressing of the vertex functions and propagators, are also included to observe the effect of using a quark propagator that correctly incorporates confinement and of modelling the dressed quark core of the rho.

A phenomenological model, the MIT bag model is also examined. This model incorporates relativistic, point-like confined quarks but ignores one-gluon exchange and centre of mass motion. Both the magnetic and electric dipole moments are calculated in the bag model providing a basis for comparison between the Dyson-Schwinger/Bethe-Salpeter framework and a purely phenomenological model, one that has been well studied over the years.

II. THE DIPOLE MOMENTS

A. The $\rho \rho \gamma$ Vertex

The form for the CP conserving $\rho \rho \gamma$ vertex is [12].

$$
\begin{aligned}
d_{\alpha}^{\nu}(p)\Gamma_{\mu\nu\sigma}d_{\beta}^{\sigma}(p') &= d_{\alpha}^{\nu}(p)[(p + p')_\mu(-g_{\nu\sigma}\mathcal{E}(q^2)
+q_\nu q_\sigma\mathcal{Q}(q^2))+(g_{\mu\nu}q_\sigma-g_{\mu\sigma}q_\nu)\mathcal{M}(q^2)]d_{\beta}^{\sigma}(p'),
\end{aligned}
$$

(1)

where $d_{\alpha\beta}$ are the rho polarisation vectors,

$$
d_{\alpha\beta}(k) = g_{\alpha\beta} - \frac{k_\alpha k_\beta}{k^2}.
$$

(2)

The form factors $\mathcal{E}$, $\mathcal{Q}$ and $\mathcal{M}$ reduce in the limit as $q^2 \rightarrow 0$ to

$$
\begin{aligned}
\mathcal{E}(0) &= 1,
\mathcal{M}(0) &= \mu, \text{ the magnetic moment in units of } e/2m
\mathcal{Q}(0) &= \frac{2}{m^2}(Q + \mu - 1), \text{ where } Q \text{ is the quadrupole moment in units of } e/m^2
\end{aligned}
$$
B. Projecting Out Charge and Dipole Terms

The integrals for the rho dipole moments that will be derived later, equations (10) and (39), are too difficult to perform analytically. This means that to isolate relevant terms they will have to be projected out from the integral before it is calculated numerically. Defining

\[ V_{\alpha\mu\beta} = d_{\alpha}(p)\Gamma_{\nu\mu\sigma}d_{\beta}'(p'), \]

and with the projection operator

\[ P_1^{\alpha\mu\beta} = d_{\nu}(p)P_\mu(-g^\nu\sigma)d_{\sigma}(p'), \]

where \( P_\mu = (p + p')_\mu \), the following result is obtained,

\[ P_1^{\alpha\mu\beta}V_{\alpha\mu\beta} \lim_{q^2 \to 0} 12\mathcal{E}(0). \]

To project out the magnetic dipole term we use the following projection operator,

\[ P_2^{\alpha\mu\beta} = d_{\nu}(p) \left[ \frac{g_{\mu\nu}' q^\sigma - g_{\mu\sigma}' q^\nu}{q^2} + \frac{P_\mu g^\mu_{\sigma}' q^\nu}{6p^2} \right] d_{\sigma}(p'), \]

which is such that

\[ P_2^{\alpha\mu\beta}V_{\alpha\mu\beta} \lim_{q^2 \to 0} 4\mathcal{M}(0). \]

C. Quark Contribution to the Magnetic Dipole Moment

All calculations below, except those involving the bag model, are carried out in Euclidean space where \( g_{\mu\nu} = \delta_{\mu\nu}, \gamma_\mu = \gamma_\mu^\dagger \) and \( \{\gamma_\mu, \gamma_\nu\} = 2\delta_{\mu\nu}. \)

The impulse approximation to the quark contribution to the magnetic dipole moment is given by (see Fig. [3])

\[ M_{fi} = \sum_{\text{flavour}=u,d} \varepsilon^\alpha(p)\varepsilon^\mu(q)\varepsilon^\beta(p') eQ_{\text{flavour}} r_{\alpha\mu\beta}^{\text{flavour}}. \]

\( Q_{\text{flavour}} \) is the charge of the quark interacting with the photon. The \( u \) and \( d \)-quarks are treated as identical except for their charge and so the contribution becomes
\[ M_{fi} = \varepsilon^\alpha(p)\varepsilon^\mu(q)\varepsilon^\beta(p')\epsilon I_{\alpha\mu\beta}, \quad (9) \]

\[ I_{\alpha\mu\beta} = (-1) \int \frac{d^4k}{(2\pi)^4} tr_{CFD}[\Gamma_\beta^\rho(k; p - q)S(k_{-+})\Gamma_\mu^{BC+CP}(k_{++}, k_{-+}) \times S(k_{++})\Gamma_\alpha^\rho(k + q/2; p)S(k_{+-})]. \quad (10) \]

Where \( k_{\alpha\beta} = k + \frac{\alpha q}{2} + \frac{\beta p}{2} \), \( \Gamma^\rho \) refers to the rho meson amplitude and \( \Gamma_\mu^{BC+CP} \) is the dressed quark-photon vertex, and \( S(p) \) is the dressed quark propagator for a quark of momentum \( p \), which will all be discussed in detail below.

**D. Quark Propagators**

The general form for the solution to the quark propagator Dyson-Schwinger equation [1] is

\[ S(p) = -i \not{p}\sigma_V(p^2) + \sigma_S(p^2) \]

\[ = \left( i \not{p}A(p^2) + B(p^2) \right)^{-1}. \quad (11) \]

A model form for the propagator is given by [3,4]

\[ \bar{\sigma}_S(x) = C_{\bar{m}}e^{-2x} + \left( \frac{1 - e^{-bx}}{b_1x} \right) \left( \frac{1 - e^{-bx}}{b_2x} \right) \left( b_0 + b_2 \left( \frac{1 - e^{-\Lambda x}}{\Lambda x} \right) \right) \]

\[ + \frac{\bar{m}}{x + \bar{m}^2} \left( 1 - e^{-2(x + \bar{m}^2)} \right), \quad (12) \]

\[ \bar{\sigma}_V(x) = \frac{2(x + \bar{m}^2) - 1 + e^{-2(x + \bar{m}^2)}}{2(x + \bar{m}^2)^2} - \bar{m}C_{\bar{m}}e^{-2x}, \quad (13) \]

where \( x = p^2/2D, \bar{\sigma}_V(x) = (2D)\sigma_V(p^2), \bar{\sigma}_S = \sqrt{2D}\sigma_S(p^2) \) and \( \bar{m} = m/\sqrt{2D}, D \) is a mass scale. (\( \Lambda = 10^{-4} \) is chosen to decouple the small and large spacelike \(-p^2\) behaviour in equation (12); i.e., to allow for \( b_0 \) to govern the ultraviolet behaviour and \( b_2 \) the infrared.) The parameters \( C_{\bar{m}}, \bar{m}, b_0, \ldots, b_3 \) are [3,4]
with the mass scale $D = 0.160$ GeV$^2$ chosen to give the correct value for $f_\pi$. This form for the quark propagator is based upon studies of the Dyson-Schwinger equation for $S(p)$ using a gluon propagator with an infrared singularity,

$$g^2 D_{\mu\nu}(k) \equiv \left(\delta_{\mu\nu} - \frac{k_{\mu}k_{\nu}}{k^2}\right)8\pi^4 D^4(k),$$

and a dressed quark-gluon vertex. Quark confinement is characterised by the non-observation of free quark states. A pole in the quark propagator in the timelike region would be a sign of a free quark state, just as a free bound state is manifest as a pole in a n-point Green’s function. Thus a sufficient condition for the lack of free quark production thresholds is the absence of timelike poles in the propagator. The model quark propagator given above is an entire function (except at timelike-$p^2 = \infty$) and so does not have a Lehmann representation. This means it can be interpreted as describing a confined particle and it ensures the lack of the unphysical singularities corresponding to free quarks in $I_{\alpha\mu\beta}$.

The dipole moments are also calculated using a form for the quark propagator developed by Mitchell and Tandy, to investigate $\rho$-$\omega$ mixing. This propagator is given by

$$\bar{\sigma}_S(x) = C\bar{m} e^{-2x} + \frac{\bar{m}}{x} \left(1 - e^{-2x}\right),$$

$$\bar{\sigma}_V(x) = \frac{e^{-2x} - (1 - 2x)}{2x^2} - \bar{m}C\bar{m} e^{-2x}.\tag{17}$$

To fix the parameters $\lambda = \sqrt{2D}$ and $C\bar{m}$, a fit to $\langle \bar{q}q \rangle$, $f_\pi$, $r_\pi$ and the $\pi$-$\pi$ scattering lengths was done. With $\frac{1}{2}(m_u + m_d) = 16$ MeV a best fit was obtained for $\lambda = 0.889$ GeV and
This form has a deficiency which can be seen in its failure to correctly model the behaviour of $\sigma_S$ away from $x = 0$, in the massless limit with dynamically broken chiral symmetry \cite{1}. The large value for the mass of the quark used is related to the deficiency of the propagator mentioned above \cite{13}.

### E. Rho-meson Amplitude

The dominant Bethe-Salpeter amplitude for the rho meson is given by \cite{14,15},

$$
\Gamma^l_{\rho \mu}(k, p) = i \left( \gamma_\mu - \frac{p_\mu p}{p^2} \right) \frac{\tau_l \Gamma_\rho(k, p)}{N_\rho},
$$

where $k$ is the relative momentum of the quark and anti-quark, $p$ is the momentum of the rho meson and $l$ and $\mu$ are flavour and Dirac indices respectively. This form ignores other allowable Dirac structure in the vector meson Bethe-Salpeter amplitude and so introduces errors of the order of 10% \cite{5}. Using the quark propagator defined in equations (12) and (13) and a Ball-Chiu quark-photon vertex (see later), Chappell uses the following approximate form for $\Gamma_\rho(k, p)$ \cite{9}

$$
\Gamma_\rho = e^{-k^2/a_1^2} + \frac{a_2}{1 + \frac{k^2}{a_1^2}},
$$

with $a_1 = 0.38845, a_2 = 0.01478, \alpha = 2$. The values for the parameters were found by fitting to the experimental values of $f_\rho$ and $g_{\rho\pi\pi}$ \cite{3}. Pichowsky and Lee, also using the quark propagator defined in equations (12) and (13) and a quark-photon vertex of the Ball-Chiu type, use an identical form for $\Gamma_\rho$, given by \cite{10}

$$
\Gamma_\rho(k, p) = e^{-k^2/a_V^2} + \frac{c_V}{1 + k^2/b_V^2}.
$$

Fitting to the experimental values for $f_\rho$ and $g_{\rho\pi\pi}$ they obtain values for the parameters of $a_V = 0.400, b_V = 0.008$ and $c_V = 125.0$. Using the quark propagator defined in equations (15) and (16) Mitchell and Tandy use a form for the amplitude $\Gamma_\rho$ given by

$$
\Gamma_\rho(k, p) = e^{-k^2/a^2},
$$
where \( a = 0.194 \text{ GeV} \). The normalisation for the rho amplitude is fixed by \([10]\)

\[
p_\mu \left( \delta_{\alpha\beta} - \frac{p_\alpha p_\beta}{p^2} \right) = N_c \text{tr}_D \int \frac{d^4 k}{(2\pi)^4} \frac{\partial S(k_+)}{\partial p_\mu} \Gamma_{\rho\alpha}(k,p) S(k_-) \Gamma_{\rho\beta}(k,p) \tag{22}
\]

\[
+ N_c \text{tr}_D \int \frac{d^4 k}{(2\pi)^4} S(k_+) \Gamma_{\rho\alpha}(k,p) \frac{\partial S(k_-)}{\partial p_\mu} \Gamma_{\rho\beta}(k,p),
\]

where \( k_\alpha = k + \frac{p_\alpha}{2} \). This condition, along with the fact that the quark-photon vertex given below obeys the Ward Identity, ensures that \( \mathcal{E}(q^2 = 0) = 1 \), i.e., that the rho has unit charge \([4]\).

Using the following transformation properties: \( S^T(-k) = C^\dagger S(k)C; \Gamma^\rho_T(-k,p) = -C^\dagger \Gamma^\rho(k,p)C \) and \( \Gamma^{\text{BC+CP}}_\mu (-p,-q) = -C^\dagger \Gamma^{\text{BC+CP}}(p,q)C \), where \( C = \gamma_2 \gamma_4 \) is the charge conjugation operator, and the Ward-Takahashi Identity, one can show that current conservation holds \([4]\), i.e.,

\[
q_\mu I_{\alpha\mu\beta} = 0. \tag{23}
\]

Given a description for the quark-photon vertex, the dipole moments of the rho can now be calculated using equations (12), (13) and (18); (12), (13) and (19), and (15), (16) and (20).

**F. Quark-Photon Vertex**

The quark-photon vertex also satisfies its own Dyson-Schwinger equation, but solving this integral equation is difficult. Despite this, a realistic ansatz for the vertex function has been developed by constraining its form using certain criteria \([17,18]\). The quark-photon vertex ansatz thus obtained is given by

\[
\Gamma^{\text{BC+CP}}_\mu (p,q) = \Gamma^{\text{BC}}_\mu (p,q) + \Gamma^{\text{CP}}_\mu (p,q). \tag{24}
\]

The Ball-Chiu vertex, \( \Gamma^{\text{BC}}_\mu \) has the form \([20]\)

\[
\Gamma^{\text{BC}}_\mu (p,q) = \frac{A(p^2) + A(q^2)}{2} \gamma_\mu + \frac{(p + q)_\mu}{p^2 - q^2} \left[ \frac{1}{2}(A(p^2) - A(q^2))(p \cdot q)
\right.
\]

\[
- i(B(p^2) - B(q^2)) \right]. \tag{25}
\]
This vertex ansatz is completely described by the dressed quark propagator and satisfies both the Ward-Takahashi and Ward Identities, is free of kinematic singularities as $q^2 \to p^2$, transforms correctly under appropriate transformations and reduces to the perturbative limit. To ensure multiplicative renormalizability Curtis and Pennington added a transverse piece to the Ball-Chiu vertex \[21\]. This term has the form given below

$$\Gamma_{\mu}^{CP}(p, q) = \left( \frac{-\imath \gamma_{\mu}(p^2 - q^2) - (p + q)_{\mu}(p - q)}{2d(p, q)} \right) \left( A(p^2) - A(q^2) \right), \quad (26)$$

with

$$d(p, q) = \frac{1}{p^2 + q^2} \left[ (p^2 - q^2)^2 + (M^2(p^2) + M^2(q^2))^2 \right], \quad (27)$$

$$M(p^2) = \frac{B(p^2)}{A(p^2)}.$$

\textbf{G. The Magnetic Dipole Moment}

The dipole moment can now be calculated. The colour, flavour and Dirac traces are performed for the integral $I_{\alpha\mu\beta}$, given in appendix A, and the charge and dipole terms projected out using the projection operators outlined above. The integrals are performed and the dipole calculated using

$$\mu = \lim_{q^2 \to 0} \mathcal{M}(q^2)$$

$$= \lim_{q^2 \to 0} P_{2}^{\alpha\mu\beta} I_{\alpha\mu\beta}/4. \quad (28)$$

The calculation is performed in the Breit Frame where

$$q = (0, 0, Q, 0),$$

$$p = \left( 0, 0, Q/2, \imath \sqrt{m_0^2 + Q^2/4} \right),$$

$$p' = \left( 0, 0, -Q/2, \imath \sqrt{m_0^2 + Q^2/4} \right).$$

A transformation to 4-dimensional hyper-spherical coordinates is carried out so that
\[ k = |k| (\sin \beta \sin \theta \cos \phi, \sin \beta \sin \theta \sin \phi, \sin \beta \cos \theta, \cos \beta), \tag{29} \]

with

\[ \int d^4k = \int_0^{\infty} k^3 dk \int_0^\pi \sin^2 \beta d\beta \int_0^\pi \sin \theta d\theta \int_0^{2\pi} d\phi. \tag{30} \]

There is no \( \phi \) dependence in the integrand so the \( \phi \) integral is performed analytically, contributing a factor of \( 2\pi \).

The integral is then performed numerically using Gaussian quadrature methods to obtain the results given in Table I. The results obtained using the framework of Chappell, and Pichowsky and Lee, are within 10% of each other which is indicative of the similarities of the approaches. The perturbative result from \[11\], and the non-relativistic SU(6) result are given for comparison. The later result is simply \[22\],

\[ \mu_{\rho^+} = \frac{e}{2m_q}. \tag{31} \]

In equation (31) the quark mass is to be interpreted a constituent quark mass of say 340 MeV \[23\], which gives \( \mu_{\rho^+} = 2.26 \frac{e}{2m_\rho} \). Thus one could say that the effect of QCD as interpreted in our calculation is to convert \( m_q \) from the current quark value to an appropriate constituent quark value. Note that the improper use of a current quark mass in equation (31) gives the large value \( \mu_{\rho^+} = 152 \frac{e}{2m_\rho} \).

H. The Electric Dipole Moment

CP violation is a feature of the weak interaction which is not well understood at present. It will, in principle, give rise to electric dipole moments for quarks and hadrons. In calculating hadronic electric dipole moments, the question of the effects of confinement and QCD in going from the quark EDM to the hadron EDM have not been studied. Here we study these effects for the rho meson.

The magnetic dipole of the rho meson comes from the term in the Salam-Delbourgo vertex function
\[(g_{\alpha\mu} q_{\beta} - g_{\beta\mu} q_{\alpha}) \mathcal{M}.\]

This results in a term in the $\rho \rho \gamma$ matrix element that looks like

\[\varepsilon(p) F.\varepsilon(p') \mathcal{M},\]

where

\[F_{\alpha\beta} = \partial_\beta A_\alpha - \partial_\alpha A_\beta\]

is the electromagnetic field tensor. To find the vertex function term that contributes to the electric dipole moment the familiar correspondence is used:

\[F_{\alpha\beta} \rightarrow \tilde{F}_{\alpha\beta} = \frac{1}{2} \varepsilon_{\alpha\beta\mu\nu} F^{\mu\nu}\]

\[\mathcal{M}(q^2) \rightarrow \mathcal{D}(q^2),\]

where $\mathcal{D}(0) = d$, the electric dipole moment in units of $e/2m$. Thus as

\[\frac{1}{2} \varepsilon_{\alpha\beta\mu\nu} F^{\mu\nu} = \varepsilon_{\alpha\beta\mu\nu} A^\mu q^\nu,\]

the term in the $\rho \rho \gamma$ vertex that defines the rho EDM is

\[\varepsilon_{\alpha\beta\mu\nu} q^\nu \mathcal{D}(q^2).\]  

Once again the electric and dipole terms will need to be projected out. The vertex function is given by

\[V_{\text{edm}}^{\alpha\beta} = d_{\alpha}^{\nu}(p) \Gamma_{\nu\sigma} d_{\beta}^{\beta}(p') \]

\[= d_{\alpha}^{\nu}(p) \left[ P_{\mu}(-g_{\nu\sigma} \varepsilon(q^2) + q_{\nu} q_{\sigma} Q(q^2)) \right. \]

\[+ (g_{\mu\nu} q_{\sigma} - g_{\mu\sigma} q_{\nu}) \mathcal{M}(q^2) + \varepsilon_{\nu\sigma\mu\rho} q^\rho \mathcal{D}(q^2) \right] d_{\beta}^{\sigma}(p').\]

Using a projection operator of the form

\[P_{3}^{\alpha\mu\beta} = - \left( \frac{1}{2q^2} \right) d^{\nu\rho}(p) \varepsilon_{\nu\sigma'}^{\rho} q_{\sigma} d^{3\sigma}(p'),\]

the result

\[P_{3}^{\alpha\mu\beta} V_{\alpha\beta} \quad \text{lim}_{q \rightarrow 0} \quad \mathcal{D}(0)\]

follows.
I. Quark Contribution to the Electric Dipole Moment

To introduce an electric dipole moment in the impulse approximation the $qq\gamma$ vertex needs to be modified to introduce a CP-violating term. Thus the following vertex is used:

$$\Gamma_\mu (p,q) = \Gamma^{BC+CP}_\mu (p,q) - iD_q \gamma_5 \sigma_{\mu \rho} (p - q) {\rho},$$

(37)

where $D_q$ is the EDM of the quark. This form for the $qq\gamma$ vertex still ensures that both the Ward-Takahashi and Ward Identities are preserved, is free of kinematic singularities as $q^2 \rightarrow p^2$ and reduces to the perturbative limit. It also still preserves multiplicative renormalizability. However we have ignored any structure of the CP-violating term which may be generated by strong or electromagnetic interactions.

Following the same procedure as outlined above, the impulse approximation to the EDM is given by

$$M_{fi} = \varepsilon^\alpha (p) \varepsilon^\mu (q) \varepsilon^\beta (p') e I^{edm}_{\alpha \mu \beta},$$

(38)

where the integral $I^{edm}_{\alpha \mu \beta}$ is given by

$$I^{edm}_{\alpha \mu \beta} = (-1) \int \frac{d^4 k}{(2\pi)^4} tr_{CFD} [\Gamma^\rho_\beta (k; p - q) S(k_{-+}) i\Gamma_\mu (k_{++}, k_{-+})$$

$$\times S(k_{++}) \Gamma^\rho_\alpha (k + q/2; p) S(k_{+-})].$$

(39)

The expanded form of the integral $I^{edm}_{\alpha \mu \beta}$ is given in appendix B. The EDM can now be calculated. Once again the Dirac traces are performed and the charge and electric dipole terms projected out using the projection operators given above. The integrals are performed and the dipole calculated using

$$d = \lim_{q^2 \rightarrow 0} D(q^2)$$

$$= \lim_{q^2 \rightarrow 0} P^{\alpha \mu \beta}_{3} I^{edm}_{\alpha \mu \beta}.$$  

(40)

The integral is again evaluated in the Breit frame.

The dipole interaction between the quark and the photon is governed by the term
\[ D_u \bar{u} \gamma_5 \sigma^{\mu\nu} q_\nu u A_\mu + D_d \bar{d} \gamma_5 \sigma^{\mu\nu} q_\nu d A_\mu, \]  

(41)

where the \( D_u \) and \( D_d \) are the electric dipole moments for the \( u \) and \( d \)-quarks respectively. In many models \( D \propto Q \) for quarks, so the following form is used,

\[ D_{\{u,d\}} = Q_{\{u,d\}} d_q. \]

(42)

The perturbative result has been calculated and it gives:

\[ d_{\text{pert.}} = 3m_q d_q \text{ in units of } e/2m. \]

(43)

The quark electric dipole moment has been left as a free parameter and so an estimate of the size of \( d_q \) is needed. The quark electric dipole moment can be generated in various models. One of these is the Weinberg model of three Higgs doublets \[24\]. In this model the quark EDM comes about due to neutral Higgs exchange with the quark dipole moment given by \[25\]

\[ d_q = \frac{e G_F}{\sqrt{2} \pi^2} m_q \sum_i X'_i Y'_i \frac{m_i^2}{m_{H_i}^2} \ln \frac{m_q^2}{m_{H_i}^2}, \]

(44)

where the \( m_{H_i} \) are the masses of the neutral Higgs and \( X'_i \) and \( Y'_i \) are mixings of the neutral Higgs. This gives a quark dipole moment of the order of \( 10^{-24} \text{e.cm} \). Thus we obtain the results for the rho electric dipole moment, in units of \( d_q \), listed in Table II. Again the perturbative result is included for comparison. For completeness, it is noted that the non-relativistic result is given by \( d_\rho = d_q \text{ e.cm} \). The results from the Chappell, and Pichowsky and Lee, amplitudes are again seen to be very close, as was the case for the magnetic moment.

III. THE BAG MODEL

There are purely phenomenological models that have been used over the years to describe the properties of hadrons. One successful and popular model which incorporates many of the features of QCD is the MIT bag model \[26,27\]. The MIT bag model includes relativistic, point-like, confined quarks and provides a phenomenological description of the
non-perturbative gluon interactions. The simplest form of the MIT model will be used, with one-gluon exchange and centre of mass motion ignored. While these results, at least for the magnetic moments of baryons, are well known we discuss them here to provide another point of comparison for the results of section [I].

The starting point for the bag model is the assumption of free quarks confined within a spherical volume of radius $R$. Solving the Dirac equation inside the sphere results in a wavefunction given by [27,28]

$$\psi(r) = \frac{N(x)}{\sqrt{4\pi}} \left( \begin{array}{c} \sqrt{\frac{w^2 + m^2}{w}} j_0 \left( \frac{xR}{w} \right) \chi \\ \sqrt{\frac{w^2}{w} i \sigma \cdot \hat{r}} j_1 \left( \frac{xR}{w} \right) \chi \end{array} \right),$$

(45)

where $w(m, R) = \sqrt{m_q^2 + x^2/R^2}$, $j_0$ and $j_1$ are spherical Bessel functions and $x$ is the quark momentum in units of $1/R$. The normalisation, $N(x)$, is given by

$$N^{-2}(x) = R^3 j_0^2(x) \frac{2w(w - 1/R) + m_q/R}{w(w - m)},$$

(46)

and the eigenfrequency $x$ by

$$\tan x = \frac{x}{1 - m_qR - (x^2 + (m_qR)^2)^{1/2}},$$

(47)

arising from the boundary condition:

$$- i \gamma \cdot \hat{r} \psi = \psi, \text{ at } r = R.$$  

(48)

To confine the quarks a “pressure” $B$ is introduced which ensures energy-momentum conservation and confinement. Thus the total energy of the bag becomes

$$E(R) = \sum_i N_i \left( m_{qi}^2 + \frac{x^2}{R^2} \right)^{1/2} + B^4 \frac{4}{3} \pi R^3,$$

(49)

where $N_i$ is the number of quarks or type $i$ inside the bag. The stability of the bag also implies that

$$\frac{\partial E(R)}{\partial R} = 0.$$  

(50)

All calculations will be carried out in the rest frame of the bag and so $E(R)$ will be equated with $m_\rho$. Equations (17), (49) and (50) will then be used to fix the variables $x$, $R$ and $B$. 

14
A. Magnetic Moment in the Bag Model

The magnetic moment is given by

\[
\mu = \frac{1}{2} \int d^3r \, r \times j_{em} \\
= \frac{1}{2} \int d^3r \, r \times \sum_i (\bar{\psi}_i \gamma \psi_i) Q_i e,
\]

where the summation is over the quarks. This gives

\[
\mu_\rho = \mu_q \sum_i \sigma_i Q_i, \tag{52}
\]

where \(\mu_q\), the magnetic dipole moment of the quark, is given by

\[
\mu_q = \frac{e}{2m_q} \frac{1}{3} m_q R \frac{4wR + 2m_q R - 3}{2(wR)^2 - 2wR + m_q R}. \tag{53}
\]

Using the standard spin-flavour wavefunction of the rho yields the results, listed in Table [III], and discussed in the final section of this paper.

B. Electric Dipole Moment in the Bag Model

Using the single particle wavefunction from above, and the P and CP violating electromagnetic current

\[
J_{\mu\nu} = -i D_q \bar{\psi} \gamma_5 \sigma_{\mu\nu} \psi, \tag{54}
\]

where \(\sigma_{\mu\nu} = \frac{i}{2} [\gamma_\mu, \gamma_\nu]\) it can be shown that

\[
J_{\mu\nu} F^{\mu\nu} = -D_q \bar{\psi} \sigma \psi \cdot E + \text{ terms involving } B, \tag{55}
\]

where \(F^{\mu\nu}\) is the standard electromagnetic tensor. Therefore

\[
d_\rho = \int_{\text{bag}} \langle \rho \uparrow | \sum_{\text{quarks}} D_q \bar{\psi} \sigma \psi | \rho \uparrow \rangle \\
= N^2 \int_0^R dr \, r^2 \left( j_0^2 \left( \frac{xR}{R} \right) + \frac{1}{3} j_1^2 \left( \frac{xR}{R} \right) \right) \langle \rho \uparrow | \sum_{\text{quarks}} D_q \sigma | \rho \uparrow \rangle. \tag{56}
\]
Thus, again using the rho spin-flavour wavefunction, the following formula for the EDM of the rho is obtained,

\[ d_\rho = N^2 \int_0^R dr \, r^2 \left( j_0^2 \left( \frac{xt}{R} \right) + \frac{1}{3} j_1^2 \left( \frac{xt}{R} \right) \right), \quad \text{in units of } d_q \text{ e cm.} \]  

(57)

This leads to the results given in Table IV and discussed below.

**IV. DISCUSSION**

Using a model form for the quark propagator obtained from the Dyson-Schwinger equations, two different phenomenological rho-meson amplitudes fitted to \( f_\rho \) and \( g_{\rho\pi\pi} \) and one used to describe \( \rho-\omega \) mixing, and a dressed quark-photon vertex, the rho dipole moments have been calculated.

All three non-perturbative models used, agree qualitatively, with the amplitude and propagator defined in [9] yielding the largest value for \( \mu_\rho \) and that of [7] the smallest. The Bethe-Salpeter amplitude of [10] resulted in the largest value for \( d_\rho \), with that of [7] yielding the smallest. Thus the values calculated for the rho magnetic and electric dipole moments are fairly robust when it comes to slight changes in the forms for both the quark propagator and the rho Bethe-Salpeter amplitude.

As seen above the inclusion of quark confinement gives greatly enhanced values over those obtained using perturbation theory. The non-perturbative results for the magnetic dipole moment are \( \sim 29\% - 51\% \) bigger than the perturbative result. While the electric dipole moment showed an even greater increase, being \( \sim 63 - 78 \) times larger than the value obtained with perturbation theory. \( d_\rho \) is linearly dependent upon the quark dipole moment and so a different model for the quark moment could change the value for \( d_\rho \) substantially. Conversely, an experimental measure for \( d_\rho \) would put a limit on \( d_q \) and possibly rule out some models.

The increase in the dipole moments is due to the inclusion of quark propagators that ensure confinement and a more accurate modelling of the momentum distribution and finite size of the rho meson. The kernel of the Bethe-Salpeter equation involves the dressed quark
and gluon propagators and so includes the effects of the quark-gluon sea. The amplitudes
that have been used here can thus be said to model these effects phenomenologically.

These calculations extend the process of using the Dyson-Schwinger/Bethe-Salpeter
framework to obtain hadron properties, to the rho meson.

The rho dipole moments have also been calculated in the MIT bag model. This phe-
nomenological model also includes confinement via the introduction of the “pressure” term
$B$. The bag is also assumed to incorporate the effects of the non-perturbative gluon ex-
change and interaction. This relativistic, confining model also yields values for the dipole
moments greater than that of perturbation theory, as was the case for the results using the
DSE/BSE framework, i.e., the results from both approaches agree qualitatively. The mag-
netic dipole moment is about $\sim 10\%$ bigger than the perturbative result, smaller than any of
the results obtained in the impulse approximation. The electric dipole calculation was $\sim 6\%$
bigger than the largest result using the Dyson-Schwinger/Bethe-Salpeter equations and $\sim 83$
times bigger than the perturbative result. Again the inclusion of confinement has led to
an enhancement in the dipole moments of the rho. Indeed, one could suggest that for the
calculation of the magnetic and electric dipole moments, the bag model gives a reasonable
estimate of the effects of confinement.

The rho meson has been used in this study, not because there is any realistic possibility
of measuring the electromagnetic moments we have calculated, but to provide some insight
into the effects of QCD and confinement on calculations of these moments in the hope of
obtaining insight into the effects these aspects of quark dynamics may have on estimates of
the electromagnetic moments of hadrons [30,31].

ACKNOWLEDGMENTS

M.B.H. wishes to thank C.D. Roberts for helpful discussions and for pointing out the
work of I. Chappell. M.B.H. also wishes to acknowledge the financial support given by the
Australian Postgraduate Award. This work was supported in part by the Australian Re-
search Grants Committee, and the Australian Department of Industry, Science and Tourism.

APPENDIX A: INTEGRAL FOR THE MAGNETIC DIPOLE MOMENT

With the definitions given above the integral \( I_{\alpha\mu\beta} \) becomes (after colour and flavour traces)

\[
I_{\alpha\mu\beta} = \frac{2tN_c}{N^2_F} \int \frac{d^4k}{(2\pi)^4} \Gamma_\mu(k)\Gamma_\rho(k + q/2) \text{tr}_D \left[ \\
\gamma_\beta \not{k}^- + \gamma_\mu \not{k}^+ + \gamma_\alpha \not{k}^+ T_1 + \gamma_\beta \not{k}^- + \gamma_\mu \gamma_\alpha T_2 \\
+ \gamma_\beta \not{k}^- + \gamma_\alpha \not{k}^+ T_3 + \gamma_\beta \not{k}^- + \gamma_\alpha k_{0+} T_4 \\
+ \gamma_\beta \not{k}^- + \gamma_\alpha \not{k}^+ T_5 + \gamma_\beta \gamma_\alpha k_{0+} T_6 \\
+ \gamma_\beta \not{k}^- + \gamma_\alpha \not{k}^+ T_7 + \gamma_\beta \not{k}^- + \gamma_\alpha k_{0+} T_8 \\
+ \gamma_\beta \gamma_\mu \gamma_\alpha \not{k}^+ T_9 + \gamma_\beta \gamma_\mu \not{k}^+ T_10 \\
+ \gamma_\beta \not{k}^- T_{11} + \gamma_\beta \gamma_\alpha k_{0+} T_{12} \\
+ \gamma_\beta \not{k}^- T_{13} + \gamma_\beta \not{k}^- + \gamma_\alpha k_{0+} T_{14} \\
+ \gamma_\beta \not{k}^- T_{15} + \gamma_\beta \gamma_\alpha k_{0+} T_{16} \right],
\]

(A1)

where the terms with an odd number of \( \gamma \) matrices have been dropped. The \( T_{1-16} \) are defined as follows:

\[
T_1 = t(V_1 + V_4)\sigma_V(k^2_{-+})\sigma_V(k^2_{++})\sigma_V(k^2_{+-}) \\
T_2 = -t(V_1 + V_4)\sigma_V(k^2_{-+})\sigma_S(k^2_{++})\sigma_S(k^2_{+-}) \\
T_3 = 2tk^2_{++}(V_2 + V_5)\sigma_V(k^2_{-+})\sigma_V(k^2_{++})\sigma_V(k^2_{+-}) \\
T_4 = -2t(V_2 + V_5)\sigma_V(k^2_{-+})\sigma_S(k^2_{++})\sigma_S(k^2_{+-}) \\
T_5 = 2tk^2_{-+}(V_2 - V_5)\sigma_V(k^2_{-+})\sigma_V(k^2_{++})\sigma_V(k^2_{+-}) \\
T_6 = -2tk^2_{-+}(V_2 - V_5)\sigma_V(k^2_{-+})\sigma_S(k^2_{++})\sigma_S(k^2_{+-}) \\
T_7 = -2V_3\sigma_V(k^2_{-+})\sigma_S(k^2_{++})\sigma_V(k^2_{+-}) \\
T_8 = -2V_3\sigma_V(k^2_{-+})\sigma_V(k^2_{++})\sigma_S(k^2_{+-})
\]
with,

\[
\begin{align*}
V_1 &= \frac{A(k_{++}^2) + A(k_{+-}^2)}{2}, \\
V_2 &= \frac{A(k_{++}^2) - A(k_{+-}^2)}{2(k_{++}^2 - k_{+-}^2)}, \\
V_3 &= \frac{-\tau(B(k_{++}^2) - B(k_{+-}^2))}{k_{++}^2 - k_{+-}^2}, \\
V_4 &= \frac{-\tau(k_{++}^2 - k_{+-}^2)(A(k_{++}^2) - A(k_{+-}^2))}{2d(k_{++}, k_{+-})}, \\
V_5 &= \frac{-(A(k_{++}^2) - A(k_{+-}^2))}{2d(k_{++}, k_{+-})}.
\end{align*}
\]

APPENDIX B: INTEGRAL FOR THE ELECTRIC DIPOLE MOMENT

The integral \( I_{\alpha\mu\beta}^{edm} \) becomes (after colour and flavour traces)

\[
I_{\alpha\mu\beta}^{edm} = \frac{2\tau N_c}{N^2} \int \frac{d^4k}{(2\pi)^4} \Gamma_\rho(k) \Gamma_\rho(k + q/2) tr_D \left[ \gamma_\beta k_{-+} + \gamma_\mu k_{+-} + \gamma_\alpha k_{++} \right] \right] T_1 + \gamma_\beta k_{-+}^\gamma_\mu^\gamma_\alpha T_2 \\
+ \gamma_\beta k_{-+} + \gamma_\alpha k_{+-} + \gamma_\mu T_3 + \gamma_\beta k_{-+}^\gamma_\alpha k_{0+} + \mu T_4 \\
+ \gamma_\beta k_{-+} + \gamma_\alpha k_{+-} + \gamma_\mu k_{0+} + \mu T_5 + \gamma_\beta^\gamma_\alpha k_{0+} + \mu T_6 \\
+ \gamma_\beta k_{-+} + \gamma_\alpha k_{0+} + \mu T_7 + \gamma_\beta k_{-+}^\gamma_\alpha k_{-0+} + \mu T_8 \\
+ \gamma_\beta k_{-+} + \gamma_5^\sigma_\mu^\rho_\gamma_\alpha k_{++} + \gamma_\beta k_{-+}^\gamma_5^\sigma_\mu^\rho_\gamma_\alpha k_{-+} + T_{10}
\]
Again dropping terms with an odd number of $\gamma$ matrices. The $T_{1-20}$ are defined as follows:

\begin{align*}
T_1 &= \gamma_2 \gamma_3 k_{++} \gamma_3 T_{11} + \gamma_3 \gamma_5 \gamma_3 k_{---} T_{12} \\
T_2 &= \gamma_2 \gamma_3 k_{0+++} T_{13} + \gamma_3 k_{++} \gamma_3 k_{---} k_{0+++} T_{14} \\
T_3 &= \gamma_2 k_{--} k_{+++} \gamma_3 k_{0+++} T_{15} + \gamma_3 k_{--} k_{+++} \gamma_3 k_{---} T_{16} \\
T_4 &= \gamma_2 k_{+++} \gamma_3 k_{---} k_{0+++} T_{17} + \gamma_3 \gamma_5 k_{0+++} T_{18} \\
T_5 &= \gamma_2 \gamma_3 \gamma_5 \gamma_5 \gamma_5 k_{++} k_{---} k_{---} T_{19} + \gamma_3 \gamma_5 \gamma_5 \gamma_5 \gamma_5 \gamma_5 \gamma_5 \gamma_5 k_{0+++} T_{20} \\
\end{align*}

(B1)
\[ T_{19} = -V_6 \sigma_S(k_{+-}^2) \sigma_V(k_{++}^2) \sigma_V(k_{+-}^2) \]

\[ T_{20} = V_6 \sigma_S(k_{+-}^2) \sigma_S(k_{++}^2) \sigma_S(k_{+-}^2), \]  \hspace{1cm} (B2)

where \( V_1 \ldots V_5 \) are defined as before and

\[ V_6 = -i d_q, ~ d_q \text{ the quark dipole moment.} \]  \hspace{1cm} (B3)
