On global fluctuations for non-colliding processes

Maurice Duits ∗

December 22, 2015

Abstract

We study the global fluctuations for a class of determinantal point processes coming from large systems of non-colliding processes and non-intersecting paths. Our main assumption is that the point processes are constructed by biorthogonal families that satisfy finite term recurrence relations. The central observation of the paper is that the fluctuations of multi-time or multi-layer linear statistics can be efficiently expressed in terms of the associated recurrence matrices. As a consequence, we prove that different models that share the same asymptotic behavior of the recurrence matrices, also share the same asymptotic behavior for the global fluctuations. An important special case is when the recurrence matrices have limits along the diagonals, in which case we prove Central Limit Theorems for the linear statistics. We then show that these results prove Gaussian Free Field fluctuations for the random surfaces associated to these systems. To illustrate the results, several examples will be discussed, including non-colliding processes for which the invariant measures are the classical orthogonal polynomial ensembles and random lozenge tilings of a hexagon.

1 Introduction

Random surfaces appearing in various models of integrable probability, such as random matrices and random tilings, are known to have a rich structure. A particular feature, one that has received much attention in recent years, is the Gaussian free field that is expected to appear as a universal field describing the global fluctuations of such random surfaces. Using the integrable structure, this has been rigorously verified in a number of models in

∗Department of Mathematics, Royal Institute of Technology (KTH), Stockholm Lindstedsvägen 25, SE-10044, Sweden. Email: duits@kth.se. Supported by the Swedish Research Council (VR) Grant no. 2012-3128.
the literature. For a partial list of reference see \[5, 6, 7, 8, 16, 28, 34, 39\]. The results so far indicate the universality of the Gaussian Free Field in this context is rather robust. In this paper, we will be interested in the global fluctuations for a particular class of models, namely that of non-colliding processes and ensembles of non-intersecting paths. For those models, we will provide a general principle that leads to Gaussian Free Field type fluctuations.

Non-colliding process and non-intersecting path ensembles form an important class of two dimensional random interacting systems. For instance, Dyson showed [19] that the Gaussian Unitary Ensemble is the invariant measure for a system of non-colliding Ornstein-Uhlenbeck processes. Replacing the Ornstein-Uhlenbeck process by its radially squared version defines a similar stochastic dynamics for the Laguerre Unitary Ensemble [32]. In Section 3 we will recall a generalization to non-colliding processes for which the classical orthogonal polynomial ensembles (continuous and discrete) are the invariant measures. Another source of models that lead non-intersecting paths are random tilings of planar domains. Lozenge tilings of a hexagon on a triangular lattice, for example, can alternatively be described by discrete random walks that start and end at opposite sites of the hexagon [21, 26]. In that way, a probability measure on all tilings of the hexagon induces a non-intersecting path ensemble.

By the tandem of the Karlin-McGregor or Gessel-Lindström-Viennot Theorem and the Eynard-Mehta Theorem, it follows that many non-colliding process are determinantal point processes, see, e.g., [27]. This makes them especially tractable for asymptotic analysis. A natural way to study the random surfaces appearing in this way is to analyze linear statistics for such determinantal point processes. The purpose of this paper is to prove Central Limit Theorems for multi-time or multi-layer linear statistics for a certain class of determinantal point processes. The conditions under which the results hold are easily verified in the classical ensembles. In particular, we will show that this Central Limit Theorem confirms the universality conjecture for the Gaussian free field in these models. We will illustrate our results by considering several examples, including dynamic extension of Unitary Ensembles and other ensembles related to (bi)orthogonal polynomials.

In the remaining part of the Introduction we give an example of what type of results we will prove by discussing a well-known model. Consider the left picture as shown in Figure 1 showing \( n \) Brownian bridges \( t \mapsto \gamma_j(t) \) that start for \( t = 0 \) at the origin and return there at \( t = 1 \). We also condition the bridges never to collide. The \( \gamma_j(t) \) turn out to have the same distribution as
the ordered eigenvalues of an \( n \times n \) Hermitian matrix for which the real and imaginary part of each entry independently (up to the symmetry) performs a Brownian bridge. Hence, at any given time \( t \in (0,1) \) the locations \( \gamma_j(t) \) have the exact same distribution of the appropriately scaled eigenvalues of a matrix taken randomly from the Gaussian Unitary Ensemble (=GUE). For more details and background on this, by now classical, example we refer to \cite{1,19}. See also \cite{46} for a general reference on Random Matrix Theory.

Because of the non-colliding condition, we can view the paths as level lines for a random surface. More precisely, if we define the height function by

\[
h_n(t,x) = \#\{j \mid \gamma_j(t) \leq x\},
\]

i.e. \( h_n(t,x) \) counts the number of paths directly below a given point \((t,x)\), then the trajectories are the lines where the stepped surface defined by the graph of \( h_n(t,x) \) makes a jump by one. The question is what happens with \( h_n \) when the size of the system grows large, i.e. \( n \to \infty \).

It turns out that as \( n \to \infty \) the normalized height function \( \frac{1}{n} h_n \) has an almost sure limit, also called the limit shape. Indeed, when \( n \to \infty \) the paths will all accumulate on a region \( \mathcal{E} \) that is usually referred to as the disordered region. We will assume that the original system is rescaled such that \( \mathcal{E} \) does not depend on \( n \) and is a non-empty open domain in \( \mathbb{R}^2 \). In fact, after a proper rescaling, the domain \( \mathcal{E} \) is the ellipse

\[
\mathcal{E} = \{(t,x) \mid x^2 \leq 4t(1-t)\}.
\]

It is well-known that the eigenvalue distribution of a GUE matrix converges to that of a semi-circle law (see, e.g., \cite{1}). This implies that we have the
following limit for the height function
\[
\lim_{n \to \infty} \frac{1}{n} \mathbb{E} h_n(t, x) = \frac{1}{2\pi t(1-t)} \int_{-\sqrt{4t(1-t)}}^{x} \sqrt{4t(1-t)-s^2} \, ds.
\]

The next question is about the fluctuations of the random surface, i.e. the behavior of \( h_n(t, x) - \mathbb{E} h_n(t, x) \). For a fixed point \((t, x)\) we note that \( h_n(t, x) \) is a counting statistic counting the number of eigenvalues of a suitably normalized GUE matrix in a given semi-infinite interval \((-\infty, x]\). The variance for such a statistic is known to be growing logarithmically \( \sim c \ln n \) as \( n \to \infty \).

Moreover, by dividing by the variance we find that
\[
\frac{h_n(t, x) - \mathbb{E} h_n(t, x)}{\sqrt{\text{Var} h_n(t, x)}} \to N(0, 1),
\]
as \( n \to \infty \). The principle behind this result goes back to Costin-Lebowitz [13] and was later extended by Soshnikov [44]. However, if we consider the correlation between several points that are macroscopically far apart,
\[
\mathbb{E} \left[ \prod_{j=1}^{R} (h_n(t_j, x_j) - \mathbb{E} h_n(t_j, x_j)) \right],
\]
we obtain a finite limit as \( n \to \infty \). When \( n \to \infty \) the random surface defined by the graph of \( h_n(t, x) - \mathbb{E} h_n(t, x) \) converges to a rough surface. The pointwise limit does not make sense (due to the growing variance) but it has a limit as a generalized function. This generalized function is, up to coordinate transform, known in the literature as the Gaussian free field.

Since the Gaussian Free Field is a random generalized function, it is natural to pair it with a test function \( \phi \), i.e.
\[
\langle h_n, \phi \rangle = \int \int h_n(t, x) \phi(t, x) \, dt \, dx,
\]
(1.3)
(as we will show in Section 2.4 the Dirichlet pairing is more appropriate, also including a coordinate transform, but this simpler pairing does show the essential idea). Then by writing \( h_n(t, x) = \sum_{j=1}^{n} \chi_{(-\infty, \gamma_j(t)]}(x) \) and by a discretization of the time integral we obtain
\[
\langle h_n, \phi \rangle = \sum_{j=1}^{n} \int_{-\infty}^{\gamma_j(t)} \phi(t, x) \, dx \, dt = \sum_{m=1}^{N} \sum_{j=1}^{n} (t_{m+1} - t_m) \int_{-\infty}^{\gamma_j(t_m)} \phi(t_m, x) \, dx,
\]
(1.4)
where we choose $N \in \mathbb{N}$ time points $t_m \in (0, 1)$ such that
\[ 0 = t_0 < t_1 < \ldots < t_N < t_{N+1} = 1, \]
and typically want the mesh $\sup_{m=0,\ldots,N}(t_{m+1} - t_m)$ to be small. The fact of the matter is that the right-hand side is a linear statistic for the point process on $\{1, \ldots, N\} \times \mathbb{R}$ defined by the locations
\[ \{(m, \gamma_j(t_m))\}_{j=1}^n, \quad \tau_m = \frac{1}{2} \ln \frac{t_m}{1 - t_m} \quad \text{and} \quad f_k^{(m)} = \frac{1}{2\pi} \int_0^{\pi} f \left( m, 2\sqrt{t_m(1 - t_m)} \cos \theta \right) \cos k\theta \, d\theta, \]
for $k \in \mathbb{N}$.

This Central Limit Theorem is a special case of a more general theorem that we will state in the next section. The main point of the present paper is to show that such results follow from a general principle for models that...
have a determinantal structure for which the integrating functions (i.e. the Hermite polynomials in the above example) satisfy a finite term recurrence. The proof of Proposition 1.1 will be discussed in Example 3.2 (see also [5] for a similar statement in the context of stochastic evolutions for Wigner matrices). The precise connection to the Gaussian Free Field will be explained in Section 2.3.

Overview of the rest of the paper

In Section 2 we will formulate the model that we will consider and state our main results, including various corollaries. The proofs of those corollaries will also be given in Section 2, but the proofs of the main results, Theorem 2.2, 2.5, 2.6 and 2.9 will be given in Section 6. Our approach is a connection to recurrence matrices, which will be explained in Section 4. Then in Section 5 we will analyze the asymptotic behavior of a general Fredholm determinant from which the proofs of the main results are special cases. Finally, in Section 3 we will provide ample examples to illustrate our results.

2 Statement of results

In this section we will discuss the general model that we will consider and state our main results. Some proofs are postponed to later sections.

2.1 The model

Determinantal point processes that come from non-colliding process and non-intersecting paths have a particular form. In this paper, we will therefore consider probability measures on \((\mathbb{R}^n)^N\) that can be written as the product of several determinants,

\[
\frac{1}{Z_n} \det (\phi_{j,1}(x_{1,k}))_{j,k=1}^n \prod_{m=1}^{N-1} \det (T_m(x_{m,i}, x_{m+1,j}))_{i,j=1}^n \\
\times \det (\psi_{j,N}(x_{N,k}))_{j,k=1}^n \prod_{m=1}^N \prod_{j=1}^n d\mu_m(x_{m,j}), \quad (2.1)
\]

where \(Z_n\) is a normalizing constant, \(d\mu_m\) are Borel measures on \(\mathbb{R}\), \(\phi_{j,1} \in L_2(\mu_N)\) and \(\psi_{j,N} \in L_2(\mu_1)\). The function \(T_m\) is such that the integral
operator $T_m : L^2(\mu_m) \to L^2(\mu_{m+1})$ defined by

$$T_m f(y) = \int f(x) T_m(x, y) d\mu_m(x),$$

is a bounded operator.

The form of (2.1) may look very special at first, but it appears often when dealing with non-colliding processes and non-intersecting paths. See, e.g., [27] and the references therein. The key is the Karlin-McGregor Theorem in the continuous setting or the Gessel-Lindström-Viennot Theorem in the discrete setting, that say that the transition probabilities of non-colliding processes can be expressed as determinants of a matrix constructed out of the transition probability for a single particle. We will discuss several explicit examples in Section 3.

It is standard that without loss of generality we can assume that

$$\int \psi_{j,N}(x) T_{N-1} T_{N-2} \cdots T_1 \phi_{k,1}(x) d\mu_N(x) = \delta_{jk}, \quad (2.2)$$

for $j, k = 1, \ldots, n$. To show this, we first recall Andrieu’s identity: For any measure $\nu$ and $f_j, g_j \in L^2(\nu)$ for $j = 1, \ldots, n$ we have

$$\int \cdots \int \det (f_j(x_k))_{j,k=1}^n \det (g_j(x_k))_{j,k=1}^n \frac{d\nu(x_1)}{j,k=1} \cdots \frac{d\nu(x_n)}{j,k=1} = n! \det \left( \int f_j(x) g_k(x) d\nu(x) \right)_{j,k=1}^n. \quad (2.3)$$

Then, by iterating (2.3), we see that $Z_n$ can be expressed as the determinant of the Gram-matrix associated to $\phi_{i,1}$ and $\psi_{j,N}$, i.e.

$$Z_n = (n!)^N \det \left( \int \psi_{i,N}(x) T_{N-1} T_{N-2} \cdots T_1 \phi_{j,1}(x) d\mu_N(x) \right)_{i,j=1}^n.$$ 

Since $Z_n$ can not vanish, it means that Gram-matrix is non-singular. The fact of the matter is that by linearity of the determinant, we can replace the $\phi_{j,1}$’s and $\psi_{k,N}$’s in the determinants in (2.1) by any other linear combinations of those functions, as long as the resulting family is linearly independent. A particular choice, for example by using the singular value decomposition of the original Gram-matrix, is to make sure that the new Gram-matrix becomes the identity. In other words, without loss of generality we can assume that we $\phi_{j,1}$ and $\psi_{k,N}$ are such that (2.2) holds. This also shows that in that case $Z_n = (n!)^N$. 

7
An important role in the analysis is played by the functions

\[ \phi_{j,m} = T_{m-1} \cdots T_1 \phi_{j,1}, \quad \psi_{j,m} = T_1^* \cdots T_{N-1}^* \psi_{j,N}, \quad (2.4) \]

for \( m = 1, \ldots, N \), where \( T_m^* \) stands for the adjoint of \( T_m \) which is given by

\[ T_m^* f(x) = \int f(y) T_m(x,y) d\mu_m(y). \]

Note that it follows from (2.2) that

\[ \int \phi_{j,m}(x) \psi_{k,m}(x) d\mu_m(x) = \delta_{jk}, \quad (2.5) \]

for \( j,k = 1, \ldots, n \) and \( m = 1, \ldots, N \). The marginals in (2.1) for the points \( \{(m,x_m)\}_{j=1}^n \) for a fixed \( m \) are given by the measure

\[ \frac{1}{n!} \det (\phi_{j,m}(x_m,k))_{j,k=1}^n \det (\psi_{j,m}(x_m,k))_{j,k=1}^n d\mu_m(x_{1,m}) \cdots d\mu_m(x_{n,m}). \quad (2.6) \]

A probability measure of this type is known in the literature as a biorthogonal ensemble [3].

It is well-known that, by the Eynard-Mehta Theorem, measures of the form (2.1) are examples of determinantal point processes. We recall that a determinantal point process is a point process for which the \( k \)-point correlation functions can be written as \( k \times k \) determinants constructed out of a single function of two variables, called the correlation kernel. More precisely, there exists a \( K_{n,N} \) such that for any test function \( g \) we have

\[ \mathbb{E} \left[ \prod_{m=1, j=1}^{N,n} \left( 1 + g(m, x_{m,j}) \right) \right] = \sum_{\ell=0}^{\infty} \int_{\Lambda^\ell} g(\eta_1) \cdots g(\eta_\ell) \det (K_{n,N}(\eta_i, \eta_j))_{i,j=1}^\ell d\nu(\eta_1) \cdots d\nu(\lambda_\ell), \quad (2.7) \]

where \( \Lambda = \{1, 2, \ldots, N\} \times \mathbb{R} \) and \( \nu \) is a measure on \( \Lambda \), called the reference measure. For the point process defined by (2.1), this kernel has the form

\[ K_{n,N}(m_1, x_1, m_2, x_2) = \begin{cases} \sum_{k=1}^n \phi_{j,m_1}(x_1) \psi_{j,m_2}(x_2), & \text{if } m_1 \geq m_2, \\ \sum_{k=1}^n \phi_{j,m_1}(x_1) \psi_{j,m_2}(x_2) - T_{m_1,m_2}(x_1, x_2), & \text{if } m_1 < m_2, \end{cases} \quad (2.8) \]
with reference measure \( \nu = \sum_{m=1}^{N} \delta_m \times \mu_m \). Here \( T_{m_1,m_2}(x_1, x_2) \) stands for the integral kernel for the integral operator \( T_{m_1} T_{m_1+1} \cdots T_{m_2-1} \). For more details and background on determinantal point process for extended kernels we refer to [4, 27, 35, 45].

For a determinantal point process, all information is in one way or the other encoded in the correlation kernel. For that reason, a common approach to various results for determinantal point processes goes by an analysis of the kernel and its properties. However, in this paper we use an alternative approach for analyzing the global fluctuations. We follow the idea of [10] and assume that the biorthogonal families admit a recurrence.

**Assumption 2.1.** We assume that \( \{ \phi_{j,1} \}_{j=1}^{N} \) and \( \{ \psi_{j,N} \}_{j=1}^{N} \) can be extended to families \( \{ \phi_{j,1} \}_{j=1}^{\infty} \) and \( \{ \psi_{j,N} \}_{j=1}^{\infty} \) such that the functions defined by

\[
\phi_{j,m} = T_{m-1} \cdots T_1 \phi_{1,m}, \quad \psi_{j,m} = T_{m}^* \cdots T_{N-1}^* \psi_{j,N},
\]

for \( m = 1, \ldots, N \), have the properties

1. **Biorthogonality:**

   \[
   \int \phi_{j,N}(x) T_{N-1} \cdots T_1 \psi_{k,1}(x) d\mu_N(x) = \delta_{jk},
   \]

   for \( j, k = 1, 2, \ldots \)

2. **Recursion:** for each \( m \in \{1, \ldots, N\} \) there is a banded matrix \( \mathbb{J}_m \) such that

\[
\begin{pmatrix}
\phi_{0,m}(x) \\
\phi_{1,m}(x) \\
\phi_{2,m}(x) \\
\vdots
\end{pmatrix}
= \mathbb{J}_m
\begin{pmatrix}
\phi_{0,m}(x) \\
\phi_{1,m}(x) \\
\phi_{2,m}(x) \\
\vdots
\end{pmatrix}.
\]

We will denote the bandwidth by \( \rho \), i.e.

\[
(\mathbb{J}_m)_{k,l} = 0, \text{ if } |k - l| \geq \rho.
\]

We will assume that \( \rho \) does not depend on \( m \) or \( n \) (but \( J_m \) may also depend on \( n \)).

Note that (2.9) and the banded structure of \( \mathbb{J}_m \) means that the functions \( \phi_{j,m} \) satisfy finite term recurrence relation

\[
\begin{align*}
 x \phi_{k,m}(x) = & \sum_{|j| \leq \rho} (\mathbb{J}_m)_{k,k+j} \phi_{k+j,m}(x). 
\end{align*}
\]
The number of terms in the recurrence equals the number of non-trivial diagonals, which is at most $2\rho + 1$. Also note that by biorthogonality we have

$$(\mathbb{I}_m)_{k\ell} = \int x\phi_{k,m}(x)\psi_{\ell,m}(x)d\mu_m(x).$$

Finally, we mention that although the arguments in this paper can likely be adjusted to allow for a varying bandwidth (but keeping the bandwidth uniformly bounded in $m,n,N$), in the relevant examples we always have a fixed bandwidth independent of $n,m$.

An important special class of examples that we will study in this paper is when the biorthogonal families are related to orthogonal polynomials. If each $\mu_m$ has finite moments, then we can define $p_{j,m}$ as the polynomial of degree $j$ with positive leading coefficient such that

$$\int p_{j,m}(x)p_{k,m}(x)d\mu_m(x) = \delta_{jk}.$$  

As we will see in Section 3 in many examples we end up with a measure \[ (2.1) \] with $\phi_{j,1} = c_{j,1}p_{j-1,m}$, $\psi_{j,N} = p_{j-1,N}/c_{j,N}$ and

$$T_m(x,y) = \sum_{j=1}^{\infty} \frac{c_{j,m+1}}{c_{j,m}} p_{j-1,m}(x)p_{j-1,m+1}(y),$$

for some coefficients $c_{j,m} \neq 0$. In that case, we find

$$\phi_{j,m}(x) = c_{j,m}p_{j-1,m}, \quad \text{and} \quad \psi_{j,m}(x) = \frac{1}{c_{j,m}}p_{j-1,m}(x). \quad (2.10)$$

Such examples satisfy Assumption 2.1. Indeed, it is classical that the orthogonal polynomials satisfy a three-term recurrence

$$xp_{k,m}(x) = a_{k+1,m}p_{k+1,m}(x) + b_{k,m}p_{k,m}(x) + a_{k,m}p_{k-1,m}(x),$$

for coefficients $a_{k,m} > 0$ and $b_{k,m} \in \mathbb{R}$. This recurrence can be written as

$$x \begin{pmatrix} p_{0,m}(x) \\ p_{1,m}(x) \\ p_{2,m}(x) \\ \vdots \end{pmatrix} = \mathcal{J}_m \begin{pmatrix} p_{0,m}(x) \\ p_{1,m}(x) \\ p_{2,m}(x) \\ \vdots \end{pmatrix}. \quad (2.11)$$

The matrix $\mathcal{J}_m$ is then a symmetric tridiagonal matrix containing the recurrence coefficients, also called the Jacobi matrix/operator associated to
It is not hard to check that in this situation, Assumption 2.1 is satisfied with
\[(\mathcal{J}_m)_{kl} = \frac{c_{k,m}}{c_{l,m}} (\mathcal{J}_m)_{kl}.\] (2.12)

We stress that such a recurrence relation is not special for orthogonal polynomials only, but appear often in the presence of an orthogonality condition. For instance, multiple orthogonal polynomial ensembles [30] also appear in the context of non-colliding processes, such as external source models. Multiple orthogonal polynomials satisfy recurrence relations involving more terms then only three, see e.g. [14].

Finally, note that in the example in the Introduction, it was needed to rescale the process as \(n \to \infty\). This rescaling means that all the parameters will depend on \(n\). Therefore we will allow \(\mu_m, \phi_{j,m}\) and \(\psi_{j,m}\) to depend on \(n\), but for clarity reasons we will suppress this dependence in the notation.

### 2.2 Fluctuations of linear statistics for fixed \(N\)

We will study linear statistics for the determinantal point process. That is, for a function \(f : \{0, 1, \ldots, N\} \times \mathbb{R} \to \mathbb{R}\) we define
\[X_n(f) = \sum_{m=0}^{N} \sum_{j=1}^{n} f(m, x_{j,m})\]

where \(\{(m, x_{j,m})\}_{j=1, m=1}^{N} \) are sampled from a probability measure of the form (2.1) satisfying Assumption 2.1. As we will see, the linear statistics \(X_n(f)\) admit a useful representation in terms of the recurrence matrices \(\mathcal{J}_m\). In fact, one of the main points of the paper is that for studying linear statistics, this representation appears to be more convenient than the representation in terms of the correlation kernel \(K_{n,N}\). In many interesting examples the asymptotic study of the relevant parts of \(\mathcal{J}_m\) are trivial, whereas the asymptotic analysis (in all the relevant regimes) of the kernel is usually tedious.

The central observation of this paper, is that the fluctuation of the linear statistic depend strongly on just small part of the operators \(\mathcal{J}_m\). More precisely, the coefficients \((\mathcal{J}_m)_{n+k, n+l}\) for fixed \(k, l\) are dominant in the fluctuations for large \(n\). The other coefficients only play a minor role. Two different models for which these coefficients behave similarly, have the same fluctuations. This is the content of the first main result.

**Theorem 2.2.** Consider two probability measures of the form (2.1) satisfying Assumption 2.1 and denote expectations with \(\mathbb{E}\) and \(\tilde{\mathbb{E}}\) and the banded
matrices by \( \tilde{J}_m \) and \( \tilde{\tilde{J}}_m \). Assume that for any \( k,l \in \mathbb{Z} \) the sequence \( \{(\tilde{J}_m)_{n+k,n+l}\}_n \) is bounded and

\[
\lim_{n \to \infty} \left( (\tilde{J}_m)_{n+k,n+l} - (\tilde{\tilde{J}}_m)_{n+k,n+l} \right) = 0, \tag{2.13}
\]

Then for any function \( f : \{0,1,\ldots,N\} \times \mathbb{R} \to \mathbb{R} \) such that \( f(m,x) \) is a polynomial in \( x \), we have for \( k \in \mathbb{N} \),

\[
E \left[ (X_n(f) - E X_n(f))^k \right] - E \left[ (X_n(f) - \tilde{E} X_n(f))^k \right] \to 0, \tag{2.14}
\]
as \( n \to \infty \).

The proof of this theorem will be given in Section 6.

This result is a genuine universality result, in the sense that there is no specification of a limit. If two families of models have the same asymptotic behavior of the recurrence matrices, then the fluctuations are also the same. As a consequence, after computing the limiting behavior for a particular example, we obtain the same result for all comparable processes.

The natural question is then what the typical behaviors are that one observes in the models of interest. As we will illustrate in Section 2.4, one important example is when the recurrence coefficients have a limiting value or, more precisely, the matrices \( J_m \) have limits along the diagonals. The fluctuations in that case are described by the following theorem.

**Theorem 2.3.** Consider a probability measure of the form \( (2.1) \) satisfying Assumption 2.1. Assume that there exists \( a_j^{(m)} \in \mathbb{R} \) such that

\[
\lim_{n \to \infty} (\tilde{J}_m)_{n+k,n+l} = a_k^{(m)}, \tag{2.15}
\]

for \( k,l \in \mathbb{Z} \) and \( m = 1,\ldots,N \). Then for any function \( f : \{1,\ldots,N\} \times \mathbb{R} \to \mathbb{R} \) such that \( f(m,x) \) is a polynomial in \( x \), we have

\[
X_n(f) - E X_n(f) \to \\
N \left( 0, 2 \sum_{m_1=1}^{N} \sum_{m_2=m_1+1}^{N} \sum_{k=1}^{\infty} k f_k^{(m_1)} f_{-k}^{(m_2)} + \sum_{m=1}^{N} \sum_{k=1}^{\infty} k f_k^{(m)} f_{-k}^{(m)} \right), \tag{2.16}
\]

where

\[
f_k^{(m)} = \frac{1}{2\pi i} \oint_{|z|=1} f(m,a^{(m)}(z)) \frac{dz}{z^{k+1}}, \tag{2.17}
\]

and \( a^{(m)}(z) = \sum_j a_j^{(m)} z^j \).
Remark 2.1. Note that each \( J_n \) is banded and hence only finitely many \( a_j^{(m)} \) are non-zero. In particular, each \( a_j^{(m)}(z) \) is a Laurent polynomial.

The proof of this theorem will be given in Section 6.

The latter result in particular applies when we are in the situation of orthogonal polynomials \( (2.10) \). In that case, the following corollary will be particularly useful to us.

**Corollary 2.4.** Consider a probability measure of the form \( (2.1) \) with \( \phi_{j,m} \) and \( \psi_{j,m} \) as in \( (2.10) \). Assume that for \( k, \ell \in \mathbb{Z} \) with \( |k - \ell| \leq 1 \) we have

\[
\lim_{n \to \infty} (J_m)_{n+k,n+l} = a_{|k-l|}^{(m)}, \tag{2.18}
\]

for some \( a_0^{(m)} \in \mathbb{R} \) and \( a_1^{(m)} > 0 \) and

\[
\lim_{n \to \infty} c_{n+k,m} = e^{\tau_m \ell - k}, \tag{2.19}
\]

for some \( \tau_1 < \tau_2 < \ldots < \tau_m \). Then for any function \( f : \{1, \ldots, N\} \times \mathbb{R} \to \mathbb{R} \) such that \( f(m, x) \) is a polynomial in \( x \) we have

\[
X_n(f) - \mathbb{E}X_n(f) \to N \left( 0, \sum_{m_1=1}^{N} \sum_{m_2=1}^{N} \sum_{k=1}^{\infty} k e^{-\tau_{m_1} - \tau_{m_2}} k \hat{f}_k^{(m_1)} \hat{f}_k^{(m_2)} \right), \tag{2.20}
\]

where

\[
\hat{f}_k^{(m)} = \frac{1}{\pi} \int_{0}^{\pi} f(m, a_0^{(m)} + 2a_1^{(m)} \cos \theta) \cos k \theta d\theta. \tag{2.21}
\]

**Proof.** This directly follows from Theorem 2.3, the relation \( (2.12) \) and a rewriting of the limiting variance. For the latter, note that by a rescaling and a symmetry argument \( (2.17) \) can be written as

\[
\hat{f}_k^{(m)} = e^{-\tau_m k} \hat{f}_k^{(m)}. \]

Moreover, by \( \hat{f}_k^{(m)} = \hat{f}_{-k}^{(m)} \) and the fact that \( \tau_\ell < \tau_k \) for \( \ell < k \), we can symmetrize the limiting variance in Theorem 2.3 to obtain the one in \( (2.20) \).

As we will see in Section 3, Theorem 2.3 and Corollary 2.4 cover several interesting examples.

In case \( N = 1 \) the determinantal point process reduces to the definition of a biorthogonal ensemble [4]. In this situation, the above results are already
proved by the author and Breuer [10]. In that paper, the approach using recurrence matrices was used for the first time and later used again in a mesoscopic analysis for orthogonal polynomials ensembles [11]. The results in [10] are a generalization of various earlier works in the determinantal setting and there is a vast amount of references on the subject. We only single out the influential work of Johansson [24] on Unitary Ensembles (and extensions to general $\beta$) and refer to [10] for further references. However, much less is known in the case of $N > 1$. To the best of the author’s knowledge, the statement above are the first general results for multi-time or multi-layer linear statistics for determinantal point processes.

**Remark 2.2.** The conditions in both Theorem 2.2 and 2.3 can be relaxed. In fact, we only need the limits (2.13) along a subsequence $\{n_k\}_k$ to conclude (2.14) along that same subsequence. Similarly, for the limits in Theorem 2.3 and Corollary 2.4. For the case $N = 1$ and $\mathcal{J}$ the Jacobi operator associated with the orthogonal polynomials corresponding to the measure $\mu$, this relates the study of possible limit theorems for the linear statistic to the study of right limits of the Jacobi operator. For the interested reader we refer to the discussion in [10]. However, in the present setup this generality seems less relevant.

**Remark 2.3.** The conditions in both Theorem 2.2 and 2.3 are not sufficient to guarantee that a limit shape exists. That is, we do not know (nor need) the limit of $\frac{1}{n} \mathbb{E} X_n(f)$.

**Remark 2.4.** In Corollary 2.4 it is easy to see that the variance is positive. In fact, in that case the variance can also be written in a different form that will be useful to us. We recall the standard integral

$$e^{-k|\tau|} = \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{k}{k^2 + \omega^2} e^{-i\omega \tau} d\tau. \quad (2.22)$$

By inserting this back into (2.20) and a simple reorganization we see that the limiting variance can be written as

$$\frac{1}{\pi} \sum_{k=1}^{\infty} \int_{-\infty}^{\infty} \left| \sum_{m=1}^{N} e^{-i\tau_m \omega} k f_k^{(m)} \right|^2 \frac{d\omega}{k^2 + \omega^2}. \quad (2.23)$$

This will be of use later on when we explain the connection of the above results with the Gaussian Free Field.

In the general case, the limiting variance is of course also positive, but this is not evident from the expression due to the lack of symmetry. This feature is already present in the $N = 1$ case, as discussed in [10].
In the situation of Corollary 2.4 we can formulate natural conditions that allow us to extend Theorem 2.3 so that it holds for more general functions $f$. In that case we will prove that the variance is continuous with respect to the $C^1$ norm. Hence we can try to extend the theorem to $C^1$ functions by polynomial approximation. For such an approximation it is convenient to work on a compact set.

**Theorem 2.5.** Suppose all the conditions in Corollary 2.4 hold and in addition there exists a compact set $E \subset \mathbb{R}$ such that either (1) all supports $S(\mu_m^{(n)}) \subset E$ for $n \in \mathbb{N}$ and $m = 1, \ldots, N$, or, more generally, (2) for every $k \in \mathbb{N}$ and $m = 1, \ldots, N$, we have

$$\int_{\mathbb{R} \setminus E} |x|^k K_{n,N}(m, x, m, x) d\mu_m(x) = o(1/n),$$

as $n \to \infty$.

Then the conclusion of Corollary 2.4 also holds for any $f : \{1, \ldots, N\} \times \mathbb{R} \to \mathbb{R}$ such that for $m \in \{1, \ldots, N\}$ the map $x \mapsto f(m, x)$ is a $C^1$ function that grows at most polynomially at $\pm \infty$.

The proof of this theorem will be given in Section 6.

The conditions in the theorem are rather mild. In case of unbounded supports, one can often show in the classical situations, by standard asymptotic methods such as classical steepest descent arguments or Riemann-Hilbert techniques, that the second condition is satisfied with exponentially small terms at the right-hand side, instead of only $o(1/n)$.

### 2.3 Varying $N_n$

Motivated by the example of non-colliding Brownian bridges in the Introduction, the natural question rises whether we can allow $N_n$ to depend on $n$ and such that $N_n \to \infty$. Indeed, in that example we wanted to view the discrete sum $\{1.4\}$ as a Riemann sum. Hence we will now consider probability measures of the form $(2.1)$ with $N = N_n$ and keep in mind that in many examples we have $T_m = P_{t_{m+1} - t_m}$ for some transition probability function $P_t$ and sampling times $t_m$.

We start with a partitioning $\alpha = t_{0(n)} < t_{1(n)} < t_{2(n)} < \ldots < t_{N(n)} < t_{N+1(n)} = \beta$, of an interval $I = [\alpha, \beta] \subset \mathbb{R}$ such that

$$\sup_m (t_{m+1(n)} - t_m(n)) \to 0,$$
as \( n \to \infty \). And then, for a function on \( g : I \times \mathbb{R} \to \mathbb{R} \) we ask for the equivalent statement of Theorems 2.2, 2.3 and 2.5 for the linear statistic

\[
Y_n(g) = \sum_{m=1}^{N_n} \frac{1}{t_{m+1}^{(n)} - t_m^{(n)}} \sum_{j=1}^{n} g(t_m^{(n)}, x_{j,m}).
\]

(2.24)

The first result is that Theorem 2.2 continues to hold when the limits (2.13) hold uniformly in \( m \).

**Theorem 2.6.** Let \( \{N_n\}_n \) be a sequence of integers such that \( N_n \to \infty \) as \( n \to \infty \). Consider two probability measures of the form (2.1) with \( N = N_n \) and satisfying Assumption 2.1 and denote the banded matrices by \( \mathbb{J}_m \) and \( \tilde{\mathbb{J}}_m \) for \( m = 1, \ldots, N_n \).

Assume that for any \( k, l \in \mathbb{Z} \) the set \( \{\mathbb{J}_m\}_{m=1}^{\infty} \) is bounded

\[
\lim_{n \to \infty} \sup_{m=1, \ldots, N_n} \left| (\mathbb{J}_m)_{n+k,n+l} - (\tilde{\mathbb{J}}_m)_{n+k,n+l} \right| = 0.
\]

(2.25)

Then for any function \( g(t,x) \) such that polynomial \( g \mapsto g(t,x) \) is a polynomial in \( x \) we have, for \( k \in \mathbb{N} \) and \( Y_n(g) \) as in (2.24),

\[
\mathbb{E} \left[ (Y_n(g) - \mathbb{E}Y_n(g))^k \right] - \mathbb{E} \left[ \left( Y_n(g) - \mathbb{E}Y_n(g) \right)^k \right] \to 0,
\]

as \( n \to \infty \).

Also Theorem 2.3 has an extension to the varying \( N_n \) setting.

**Theorem 2.7.** Let \( \{N_n\}_n \) be a sequence of integers such that \( N_n \to \infty \) as \( n \to \infty \) and suppose that for each \( n \) we have a probability measures of the form (2.1) with \( N = N_n \) and satisfying Assumption 2.1.

Assume that there exists piecewise continuous functions \( a_k(t) \) on the interval \( I \) such that, for \( k, l \in \mathbb{Z} \),

\[
\lim_{n \to \infty} \sup_{m=1, \ldots, N_n} \left| (\mathbb{J}_m)_{n+k,n+l} - a_{k-l}(t_m^{(n)}) \right| = 0.
\]

Then for any function \( g(t,x) \) such that \( t \mapsto g(t,x) \) is piecewise continuous and \( x \mapsto g(t,x) \) is a polynomial, we have that \( Y_n(g) \) as defined in (2.24) satisfies

\[
Y_n(g) - \mathbb{E}Y_n(g) \to N \left( 0, \sum_{k=1}^{\infty} 2 \int_{\alpha<t_1<t_2<\beta} kg_k(t_1)g_{-k}(t_2)dt_1dt_2 \right)
\]

16
as \( n \to \infty \), with

\[
g_k(t) = \frac{1}{2\pi i} \oint_{|z|=1} g \left( t, \sum_{\ell} a_{\ell}(t)z^\ell \right) \frac{dz}{z^{k+1}}.
\]

As before, in the special case that we deal with orthogonal polynomials the latter theorem takes the following form.

**Corollary 2.8.** Let \( a_0(t), a_1(t) \) and \( \tau(t) \) be piecewise continuous functions on an interval \( I \) and assume that \( \tau(t) \) is increasing.

Suppose that for each \( n \) we have a probability measures of the form (2.1) satisfying Assumption 2.1 with \( \phi_{j,m} \) and \( \psi_{j,m} \) as in (2.10) and assume that for \( k, \ell \in \mathbb{Z} \), for \( k, \ell \in \mathbb{Z} \) with \(|k - \ell| \leq 1\), we have

\[
\lim_{n \to \infty} \sup_{m=1,\ldots,N_n} \left| (J_m)_{n+k,n+\ell} - a_{|k-\ell|}(t^{(n)}_m) \right| = 0, \tag{2.26}
\]

and

\[
\lim_{n \to \infty} \sup_{m=1,\ldots,N_n} \left| \frac{c_{n+k,m}}{c_{n+k,l}} - e^{\tau(t^{(n)}_m)(k-\ell)} \right| = 0. \tag{2.27}
\]

Then for any function \( g : I \times \mathbb{R} \to \mathbb{R} \) such that \( t \mapsto g(t,x) \) is piecewise continuous and \( x \mapsto g(t,x) \) is a polynomial, we have that \( Y_n(g) \) as defined in (2.24) satisfies

\[
Y_n(g) - EY_n(g) \to N \left( 0, \sum_{k=1}^{\infty} \int_I \int_I e^{-|\tau(t_2) - \tau(t_1)|k} g_k(t_1)g_{-k}(t_2)dt_1 dt_2 \right)
\]

as \( n \to \infty \), with

\[
g_k(t) = \frac{1}{\pi} \int_0^\pi g \left( t, a_0(t) + 2a_1(t) \cos \theta \right) \cos k\theta d\theta.
\]

**Proof.** The proof follows from Theorem 2.7 in the same way as Corollary 2.4 followed from 2.3. \( \square \)

**Remark 2.5.** By (2.22) we can write the variance also as

\[
\frac{1}{\pi} \sum_{k=1}^{\infty} \int_{\omega^2 + k^2}^{\infty} \left| \int_I e^{-i\omega \tau(t)} g_k(t)dt \right|^2 d\omega. \tag{2.28}
\]

This will be useful later on.
Again, Theorem 2.7 is stated for a function \( g(t,x) \) that is a polynomial in \( x \). Under similar conditions as in Theorem 2.5 we can extend this to a larger class of functions.

**Theorem 2.9.** Assume that all the conditions of Corollary 2.8 hold. In addition, assume that there exists a compact set \( E \subset \mathbb{R} \) such that either

1. all supports \( S(\mu_m^{(n)}) \subset E \) for \( n \in \mathbb{N} \) and \( m = 1, \ldots, N \),

or, more generally,

2. for every \( k \in \mathbb{N} \) and we have

\[
\sup_{m=1,\ldots,N_n} \int_{\mathbb{R}\setminus E} |x|^k K_{n,N}(m,x,m,x) d\mu_m(x) = o(1/n),
\]

as \( n \to \infty \).

Moreover, assume that \( t_m^{(n)} \) are such \( N_n \sum_{m=1}^{N_n} (t_{m+1}^{(n)} - t_m^{(n)})^2 \) is bounded in \( n \). Then Theorem 2.7 also holds with any \( g \) such that \( x \mapsto g(t,x) \) is a \( C^1 \) function growing at most polynomially at \( \pm \infty \).

### 2.4 Connection to Gaussian Free Field

Finally, we discuss the relation of the above results with the Gaussian Free Field. We will focus on the situation of Theorem 2.7 and such that one of the conditions in Theorem 2.9 is valid, such that Theorem 2.7 holds for continuously differentiable \( g \).

We will start by recalling the definition of the Gaussian Free Field without a detailed justification. More details and background can be found in the survey [40].

Let \( \mathcal{D} \) be a simply connected domain in \( \mathbb{R}^2 \). With this domain we consider the space of test functions \( \mathcal{H}_\nabla \) defined as follows: we start with space \( C^1_0(\mathcal{D}) \) of all continuously differentiable functions that vanish at the boundary of \( \mathcal{D} \). On that space we define the norm

\[
\|\phi\|^2_{\nabla} = \pi \iint_\mathcal{D} |\nabla \phi(w)|^2 dm(w),
\]

where \( dm \) stands for the planar Lebesgue measure on \( \mathcal{D} \). The space of test function \( \mathcal{H}_\nabla \) is then defined as the closure of \( C^1_0(\mathcal{D}) \) with respect to this norm. Now that we have the space of test functions, we then define the Gaussian free field to be the collection of Gaussian random variables \( \langle F, \phi \rangle_\nabla \) indexed by \( \phi \in \mathcal{H}_\nabla \) such that

\[
\langle F, \phi \rangle_\nabla \sim N(0, \|\phi\|^2_\nabla),
\]
and such that $\phi \mapsto \langle F, \phi \rangle$ is linear.

Now let us first focus on the example given in the introduction and let $h_n$ be the height function as defined in (1.1). The statement now is that the fluctuations of $h_n - \mathbb{E} h_n$ are described by the Gaussian free field in appropriately chosen coordinates. That is, there is a simply connected domain $D$ and a homeomorphism

$$\Omega : D \to \mathcal{E} : w = (\tau, \theta) \mapsto (t, x),$$

where $\mathcal{E}$ is the ellipse (1.2), such that the push-forward of $h_n - \mathbb{E} h_n$ under the map $\Omega$. That is,

$$\langle h_n \circ \Omega, \phi \rangle - \langle \mathbb{E} h_n \circ \Omega, \phi \rangle \to N(0, \|\phi\|^2_\nabla),$$

as $n \to \infty$, for some natural pairing $\langle h_n \circ \Omega, \phi \rangle$. It is important to note that the Gaussian Free Field is a universal object, the coordinate transform is not and depends on the specific problem at hand.

The relation with linear statistics is explained as follows (see also [16]), which also gives the precise form of the pairing $\langle h_n \circ \Omega, \phi \rangle$ that we will use. First, by integration by parts and a change of variables we obtain

$$\pi \int_D \nabla h_n(\Omega(w)) \cdot \nabla \phi(w) dm(w) = -\pi \int_{\mathcal{E}} h_n(x, t) \Delta \phi(w(t, x)) \frac{d(\tau, \theta)}{d(x, t)} dx dt,$$

where $d(\tau, \theta)/d(x, t)$ stands for the Jacobian of the map $\Omega^{-1}$. We then use the fact that $h_n(t, x) = \sum_{j=1}^{n} \chi_{(-\infty, \gamma_j(t))]}(x)$ to rewrite the right-hand side as

$$-\pi \int \sum_{j=1}^{n} \int_{-\infty}^{\gamma_j(t)} \Delta \phi(w(t, x)) \frac{d(\tau, \theta)}{d(x, t)} dx dt$$

Finally, the pairing $\langle h_n, \phi \rangle$ is then defined by a discretization of the integral over $t$,

$$\langle h_n, \phi \rangle = -\sum_{m=1}^{N} \frac{1}{t_{m+1} - t_m} \sum_{j=1}^{n} \pi \int_{-\infty}^{\gamma_j(t_m)} \Delta \phi(w(t_m, x)) \frac{d(\tau, \theta)}{d(x, t)} dx.$$  \hspace{1cm} (2.30)

Now note that $\langle h_n, \phi \rangle = Y_n(g)$ where $Y_n(g)$ is the linear statistic as in (2.24) with

$$g(t, y) = -\pi \int_{-\infty}^{y} \Delta \phi(w(t, x)) \frac{d(\tau, \theta)}{d(x, t)} dx.$$  \hspace{1cm} (2.30)

Hence the pairing of the height function with a test function, reduces to a linear statistic for the point process $\{\gamma_j(t_m)\}_{j=1, m=1}^{n, N}$ and we can apply
Proposition 1.1 to find its limiting fluctuations, which leads to (2.29) as we will show below.

We will state the result in the more general setup of Theorem 2.9. That is we consider a probability measure of the form in (2.1) satisfying Assumption 2.1 in the orthogonal polynomial situation (2.10). We then assume that there exists interval \( I = [\alpha, \beta] \) and functions \( a_0 : I \to \mathbb{R}, a_1 : I \to \mathbb{R} \) and an increasing function \( \tau(t) \) such that we have the limits (2.26) and (2.27) for some partitioning \( \{t_m^{(n)}\} \) of \( I \). This gives us the random points \( \{(m, x_{j,m})\}_{j=1,m=1}^{n,N} \) and we ask for the fluctuations of the height function defined by

\[
h(t_m^{(n)}, x) = \#\{j \mid x_{j,m} \leq x\}.
\]

The coordinate transform is now constructed as follows. First, define

\[
\mathcal{E} = \{(t, x) \mid -2a_1(t) \leq x - a_0(t) \leq 2a_1(t)\}.
\]

Note that \( \tau(t) \) is strictly increasing as a function of \( t \) and hence it has an inverse \( t(\tau) \). Then, with

\[
\mathcal{D} = \{(\tau, \theta) \mid \tau \in (\tau(\alpha), \tau(\beta)), \theta \in (0, \pi)\},
\]

the map

\[
\Omega : \mathcal{D} \to \mathcal{E} : (\tau, \theta) \mapsto (t(\tau), x(\tau, \theta)) = (t(\tau), 2a(t(\tau)) \cos \theta),
\]

is a bijection and has the inverse

\[
\Omega^{-1} : \mathcal{E} \to \mathcal{D} : (t, x) \mapsto (\tau(t), \theta(t, x)) = \left(\tau(t), \arccos \frac{x}{2a(t)}\right).
\]

In this setting, we have that the push-forward by \( \Omega \) of the fluctuations of the height function \( h_n \) are governed by the Gaussian Free Field on \( \mathcal{D} \) in the following sense.

**Theorem 2.10.** Let \( \{(m, x_{j,m})\}_{j,m=1}^{n,N} \) be random from a probability measure of the form (2.1) satisfying the conditions in Theorem 2.9 with the parameters as described above.

Let \( \phi \) be a twice continuously differentiable real-valued function with compact support in \( \mathcal{D} \) and consider the pairing

\[
\langle h_n, \phi \rangle_{\nabla} := -\sum_{m=1}^{N} \frac{1}{t_{m+1}^{(n)} - t_m^{(n)}} \sum_{j=1}^{n} \pi \int_{-\infty}^{x_{j,m}} \Delta \phi(w(t, x)) \frac{d(\tau, \theta)}{d(x, t)} dx.
\]

20
Then, as $n \to \infty$,

$$\langle h_n, \phi \rangle \nabla - \mathbb{E}[\langle h_n, \phi \rangle \nabla] \to N(0, \|\phi\|_\nabla^2),$$

in distribution.

**Proof.** We start by recalling that $\langle h_n, \phi \rangle \nabla$ is the linear statistic $Y_n(g)$ as in (2.24) with

$$g(t, y) = -\pi \int_{-\infty}^y \Delta \phi(w(t, x)) \frac{d(\tau, \theta)}{d(x, t)} dx.$$

Note that $x \mapsto g(t, x)$ is a continuously differentiable and bounded function. Moreover, the point process satisfies the assumptions in Theorem 2.9 so that, as $n \to \infty$,

$$\langle h_n, \phi \rangle \nabla - \mathbb{E}[\langle h_n, \phi \rangle \nabla] \to N(0, \sigma(g)^2),$$

in distribution, with (see Remark 2.4)

$$\sigma(g)^2 = \frac{1}{\pi} \sum_{k=1}^\infty \int_{\mathbb{R}} \frac{k^2}{\omega^2 + k^2} \left| \int_1 e^{-ir(t)\omega} g_k(t) dt \right|^2 d\omega.$$

and

$$g_k(t) = \frac{1}{\pi} \int_0^\pi g(t, a_0(t) + 2a_1(t) \cos \theta) \cos k\theta d\theta.$$

It remains to show that we can rewrite the variance so that it matches with the one in the statement.

We start by noting that the Jacobian for the map is given by

$$\frac{d(\tau, \theta)}{d(t, x)} = \tau'(t) \frac{\partial \theta}{\partial x}.$$

Then, by a change of variables we have

$$g(t, y) = \pi \int_{a_0(t)-2a_1(t)}^y \Delta \phi(\tau(t), \theta(t, x)) \frac{d(\tau, \theta)}{d(t, x)} dx$$

$$= \pi \tau'(t) \int_{a_0(t)-2a_1(t)}^y \Delta \phi(\tau(t), \theta(t, x)) \frac{\partial \theta}{\partial x} dx = \pi \tau'(t) \int_0^{\theta(t, y)} \Delta \phi(\tau(t), \theta) d\theta.$$

Clearly, since $\Omega$ and $\Omega^{-1}$ are each others inverse maps, we have

$$\theta(t, a_0(t) + 2a_1(t) \cos(t)) = \theta.$$
and hence
\[ g(t, a(t) + 2a_1(t) \cos \theta) = \pi' t(t) \int_0^\theta \Delta \phi(t, \tilde{\theta}) d\tilde{\theta}. \]

This implies that
\[
kg(t) = \frac{1}{\pi} \int_0^\pi g(t, a(t) + 2a_1(t) \cos \theta) k \cos k\theta d\theta
\]
\[
= \pi' t(t) \int_0^\pi \Delta \phi(t, \tilde{\theta}) d\tilde{\theta} k \cos k\theta d\theta = \pi' t(t) \int_0^\pi \Delta \phi(t, \theta) k \sin k\theta d\theta
\]
using integration by parts in the last step. We then continue by inserting the last expressions and using the fact that \( \phi \) has compact support in \( D \),
\[
k \int_I e^{-i\tau(t)\omega} g_k(t) dt = \int_I \int_0^\pi e^{-i\tau(t)\omega} \Delta \phi(t, \theta) k \sin k\theta d\theta d\tau(t) dt
\]
\[
= \int_R \int_0^\pi e^{-i\tau(t)\omega} \Delta \phi(t, \theta) k \sin k\theta d\theta d\tau = \pi \left( G \Delta \phi \right)(\omega, k),
\]
where \( G \) is the operator
\[
G f(\omega, k) = \frac{1}{\pi} \int_R \int_0^\pi f(\tau, \theta) e^{-i\omega\tau} \sin k\theta d\theta d\tau.
\]

Since \( \{ \sqrt{2/\pi} \sin k\theta \}_{k=1}^\infty \) is an orthonormal basis for \( L_2([0, \pi]) \) and since the integral over \( \tau \) is the usual Fourier transform (with normalization \( (2\pi)^{-1/2} \)), we see that \( G \) defines a unitary transform from \( L_2(D) \) to \( L_2(R) \times l_2(N) \). It is also easy to check that \( G \Delta \phi(\omega, k) = -(\omega^2 + k^2)G \phi(\omega, k) \). We then apply Plancherel’s Theorem to write
\[
\frac{1}{\pi} \sum_{k=1}^\infty \int_R \frac{k^2}{\omega^2 + k^2} \left| \int_I e^{-i\tau(t)\omega} g_k(t) dt \right|^2 d\omega = \pi \sum_{k=1}^\infty \int_R \frac{|(G \Delta \phi)(\omega, k)|^2}{\omega^2 + k^2} d\omega
\]
\[
- \pi \sum_{k=1}^\infty \int_R \overline{G \Delta \phi(\omega, k)} G \phi(\omega, k) d\omega = -\pi \int_D \overline{\phi \Delta \phi} = \pi \int_D \phi \Delta \phi = \| \phi \|_V^2,
\]
and this proves the statement.

\[ \square \]

3 Examples

In this section we will illustrate the main results by discussing several examples.
3.1 Stationary non-colliding processes

The first class of examples is that of non-colliding processes for which the classical orthogonal polynomials ensembles are the invariant measures. The construction we will follow is a well-known approach using Doob’s $h$-transform and the Karlin-McGregor Theorem, see e.g. [31] for a discussion. An alternative way of defining the processes is to start with a generator for a single particle process and then define an $n$-particle process by constructing a generator on the space of symmetric functions [9, 36].

Suppose we are given a Markov process for a single particle and let us assume that it has a transition function $P_t(x, y)d\mu(y)$ on a subset $E \subset \mathbb{R}$ that can be written as

$$P_t(x, y)d\mu(y) = \sum_{j=0}^{\infty} e^{-\lambda_j t} p_j(x)p_j(y)d\mu(y), \quad (3.1)$$

where $0 = \lambda_0 < \lambda_1 < \lambda_2 < \ldots$ and $p_j(x)$ are orthogonal polynomials with respect to $d\mu(y)$. That is, $\{p_k\}_k$ is the unique family of polynomials such that $p_k$ is a polynomial of degree $k$ with positive leading coefficient and

$$\int p_k(x)p_l(x)d\mu(x) = \delta_{k,l}.$$

In other words, we assume that the generator for the Markov process has eigenvectors $p_j$ and eigenvalues $\lambda_j$. It is standard that the classical orthogonal polynomials appear in this way, as we will see.

We then construct a Markov process on the Weyl chamber

$$\mathcal{W}_n = \{(x_1, \ldots, x_n) \in \mathbb{R}^n \mid x_1 < \ldots < x_n\}.$$

First we note that by a theorem of Karlin-McGregor it follows, under general conditions on the Markov process, that the joint probability distribution for the positions $y_j$ after time $t > 0$ of particles that (1) each perform a single particle process given by $P_t$, (2) start at $x_1, \ldots, x_n$ and (3) are conditioned not to collide in $[0, 1]$, is given by

$$\det (P_t(x_i, y_j)).$$

Then by (2.3) and (3.1) it follows that
\[
\int_{W_n} \det (P_t(x_i, y_j)) \det (p_{j-1}(y_k))_{j,k=1}^n \, d\mu(y_1) \cdots d\mu(y_n)
\]
\[
= e^{-t \sum_{j=0}^{n-1} \lambda_j} \det (p_{j-1}(x_k))_{j,k=1}^n.
\]

Moreover, \(\det (p_{j-1}(x_k))_{j,k=1}^n = c \prod_{1 \leq i < j \leq n} (x_j - x_i)\) is positive. Hence it is a positive harmonic function and we can apply Doob’s \(h\)-transform to arrive at the transition function

\[
P_t(\vec{x}, \vec{y}) = e^{t \sum_{j=0}^{n-1} \lambda_j} \det (P_t(x_i, y_j))_{i,j=1}^n \frac{\det (p_{j-1}(y_k))_{j,k=1}^n}{\det (p_{j-1}(x_k))_{j,k=1}^n}.
\]

This defines the Markov process on \(W_n\) that we will be interested in. Finally, it is not hard to show from (2.3) that the unique invariant measure is given by the orthogonal polynomial ensemble [31],

\[
\left( \det (p_{j-1}(x_k))_{j,k=1}^n \right)^2 d\mu(x_1) \cdots d\mu(x_n).
\]

In other words, the above construction provides a way for defining a stochastic dynamics for which the classical orthogonal polynomial ensembles are the invariant measures.

We consider this Markov process in the stationary situation. That is, we fix \(t_1 < t_2 < \ldots < t_N \in \mathbb{R}\) and start the Markov process with the invariant measure at \(t_1\). Then we obtain a probability measure for the locations at \(t_m\)

\[
\det (p_{j-1}(x_k(t_1)))_{j,k=1}^n \prod_{m=1}^{N-1} \det (P_{t_{m+1}-t_m}(x_j(t_m), x_k(t_{m+1})))_{j,k=1}^n \times \det (p_{j-1}(x_k(t_N)))_{j,k=1}^n \prod_{m=1}^{N} \prod_{j=1}^{n} d\mu(x_j(t_m)),
\]

which, after a symmetrization, is exactly of the form (2.1). In fact it is an example of an orthogonal polynomial situation as given in (2.10) with \(c_{j,m} = e^{-t_m \lambda_j}\). Before we apply Corollary 2.4 we recall that the orthogonal polynomials on the real line are subject to a three term recurrence relation

\[
xp_k(x) = a_{k+1}p_{k+1}(x) + b_kp_k(x) + a_kp_{k-1}(x),
\]

for some numbers \(b_k \in \mathbb{R}\) and \(a_k > 0\). We recall that we allow the measure \(\mu\) to vary with \(n\) so that also \(b_k\) and \(a_k\) may vary with \(n\) and hence we will write \(a_k = a_k^{(n)}\) and \(b_k^{(n)}\).
Theorem 3.1. Suppose that, for some \( a > 0 \) and \( n \in \mathbb{R} \) we have
\[
\begin{align*}
a_{n+k}^{(n)} &\to a, \\
b_{n+k}^{(n)} &\to b,
\end{align*}
\]
and choose \( t_j \) such that, for some \( \tau_j \) and sequence \( \kappa_n \),
\[
\kappa_n(\lambda_{n+k} - \lambda_{n+l})t_j \to (k-l)\tau_j
\]
as \( n \to \infty \). Then for any \( f : \{1, \ldots, N\} \times \mathbb{R} \) such that \( f(m, x) \) is a polynomial, we have
\[
X_n(f) - \mathbb{E}X_n(f) \to N \left( 0, \sum_{m_1, m_2=1}^{N} \sum_{k=1}^{\infty} ke^{-|\tau_{m_1} - \tau_{m_2}|k} f_k^{(m_1)} f_k^{(m_2)} \right),
\]
where
\[
f_k^{(m)} = \frac{1}{\pi} \int_0^{\pi} f(m, 2a \cos \theta + b) \cos k\theta d\theta.
\]
Moreover, for any \( g : I \times \mathbb{R} \to \mathbb{R} \) such that \( g(t, x) \) is a polynomial in \( x \) we have that \( Y_n(g) \) as defined in \([2.24] \) satisfies
\[
Y_n(g) - \mathbb{E}Y_n(g) \to N \left( 0, \sum_{k=1}^{\infty} \int_{I \times I} e^{-|\tau(t_2) - \tau(t_1)|k} g_k(t_1)g_{-k}(t_2) dt_1 dt_2 \right)
\]
as \( n \to \infty \), with
\[
g_k(t) = \frac{1}{\pi} \int_0^{\pi} g(t, a_0 + 2a_1 \cos \theta) \cos k\theta d\theta.
\]
Proof. This is a direct consequence of Corollaries \([2.4] \) and \([2.8] \) with \( c_{j,m} = e^{-t_m^{(n+j)}} \).

The point is now that for the Markov process related to the classical polynomials we can easily verify the stated condition by looking up the explicit values of the parameters in standard reference works on classical orthogonal polynomials, such as \([29] \).

We will now illustrate the results with some examples. To start with, we consider the classical Hermite, Laguerre and Jacobi polynomials, which are well-known to be eigenfunctions for a second order differential operator that can be used as the generator for the Markov process.
Figure 2: The left figure shows a sampling from a stationary non-colliding process generated by the Ornstein-Uhlenbeck process of size $n = 20$. At the right we intersect the trajectories at multiple times $t_m$.

**Example 3.2** (Non-colliding Ornstein-Uhlenbeck processes). Let us start where we take $P_t(x,y)$ according to the Ornstein-Uhlenbeck process. This is the model that was considered by Dyson [19] for $\beta = 2$. In that case we have

$$P_t(x,y)\,d\mu(y) = \frac{1}{\sqrt{2\pi(1-e^{-2t})}} e^{-\frac{(e^{-t}x-y)^2}{2(1-e^{-2t})}} dy,$$

as the transition function. By Mehler’s formula for the Hermite polynomials this can be expanded as

$$P_t(x,y)\,d\mu(y) = \sum_{j=0}^{\infty} e^{-jt}H_j(x)H_j(y)e^{-y^2/2}dy,$$

where $H_j(y)$ are the normalized Hermite polynomials where the orthogonality is with respect to $e^{-y^2/2}dy$ on $\mathbb{R}$.

The Hermite polynomials satisfy the recurrence

$$xH_k(x) = \sqrt{k+1}H_{k+1}(x) + \sqrt{k}H_{k-1}(x).$$

The recurrence coefficients grow and in order to get a meaningful limit we need to rescale the process. Indeed, when $n \to \infty$ the paths at any given time $t$ fill the interval $(-2\sqrt{n}, 2\sqrt{n})$ and we rescale the space variable and introduce the new variable $\xi$ by

$$x = \sqrt{n}\xi.$$

Then the rescaled orthonormal polynomials are $p_k(\xi) = n^{-1/4}H_k(\sqrt{n}\xi)$ and for these polynomials we have the following recursion

$$p_k(\xi) = \sqrt{\frac{k+1}{n}} p_{k+1}(\xi) + \sqrt{\frac{k}{n}} p_{k-1}(\xi).$$
One readily verifies that
\[ a^{(n)}_{n+k,n} \to 1, \quad b^{(n)}_{n+k,n} = 0. \]

Moreover, since \( \lambda_j = j \), we also have
\[ (\lambda_{n+k} - \lambda_{n+\ell})t_j = (k - \ell)t_j. \]

Therefore, the conditions of Theorem 3.1 are satisfied with \( a = 1, b = 0 \) and \( \tau_j = t_j \). In fact, for the Hermite polynomials one can verify that the second condition in Theorem 2.5 is satisfied and hence Theorem 3.1 also holds for function \( f : \{1, \ldots, N\} \times \mathbb{R} \) such that \( x \to f(m, x) \) is a continuously differentiable function that grows at most polynomially at \( \pm \infty \). This follows for example after a classical steepest decent analysis on the integral representation of the Hermite polynomials or by a Riemann-Hilbert analysis. We will leave the tedious details to the reader.

Finally, we note that the non-colliding brownian bridges model from the Introduction can be obtained from the above model after the change of variables
\[ (t, \xi) \mapsto \left( \frac{1}{1 + e^{-t} \cosh \xi} \right). \]

This is discussed in, for example, [26] and we refer to that paper for more details. This also proves Proposition 1.1.

**Example 3.3** (Non-colliding squared radial Ornstein-Uhlenbeck processes).
In the next example, we replace the Ornstein-Uhlenbeck process with its squared radial version. That is,
\begin{align*}
P_t(x, y) d\mu(y) &= \frac{1}{1 - e^{-t}} \left( \frac{y}{xe^{-t}} \right)^{r/2} e^{-\frac{xy}{1 - e^{-t}}} e^{-\frac{x}{1 - e^{-t}}} I_r \left( \frac{2 e^{-t} xy}{1 - e^t} \right)
\end{align*}
on \([0, \infty)\) where \( r > -1 \) is a parameter and \( I_r \) stands for the modified Bessel function of the first kind of order \( r \). The squared radial Ornstein-Uhlenbeck process is related to the squared Bessel process in a similar way as the Ornstein-Uhlenbeck process is to Brownian motion. Indeed, the squared Bessel process can be obtained by a change of variables. The latter process has been studied in the literature in the context of non-colliding processes before. In [32] it was used to define a dynamic version of the Laguerre ensemble from Random Matrix Theory.
To see its connection we note that we can expand the transition function as

\[ P_t(x, y) d\mu(y) = \sum_{j=1}^{\infty} e^{-jt} \frac{j!}{\Gamma(j+r+1)} L_j^{(r)}(x) L_j^{(r)}(x) y^r e^{-y} dy, \]

where \( L_j^{(r)}(x) \) is the generalized Laguerre polynomial of degree \( r \) (with orthogonality with respect to \( y^r e^{-y} dy \)). These polynomials satisfy the recursion

\[ xL_k^{(r)} = -(k + 1)L_{k+1}^{(r)}(x) + (2k + r + 1)L_k^{(r)}(x) - (k + r)L_{k-1}^{(r)}(x). \]

Note that the recursion coefficients are growing, which means that we need to rescale the process. Moreover, the Laguerre polynomials are not normalized. To be able to apply Theorem 3.1 we therefore define the normalized and rescaled polynomials by

\[ p_k(\xi) = \sqrt{\frac{k!}{\Gamma(k+r+1)}} L_k^{(r)}(n\xi)(-1)^k. \]

The \( p_k \) then satisfy the recursion

\[ \xi p_k(\xi) = \frac{\sqrt{(k+1)(k+r+1)}}{n} p_{k+1}(\xi) + \frac{(2k + r + 1)}{n} p_k(\xi) + \frac{\sqrt{k(k+r)}}{n} p_{k-1}(\xi). \]

Then one readily verifies that

\[ a_{n+1,k,n}^{(n)} \to 1, \quad b_{n+1,k,n}^{(n)} \to 2. \]

Moreover, as in the previous example we have \( \lambda_j = j \), and hence also

\[ (\lambda_{n+k} - \lambda_{n+\ell}) t_j = (k - \ell) t_j. \]

Therefore, the conditions of Theorem 3.1 are satisfied with \( a = 1, b = 2 \) and \( \tau_j = t_j \). To the best of our knowledge we believe that this example is a new result that has not appeared before.

Also in the case it is possible to prove the conditions of Theorems 2.5 and 2.9. 

**Example 3.4 (Non-colliding Jacobi diffusions).** The last of the continuous examples is that of Jacobi diffusions, which have also been discussed in [18, 22]. For \( \alpha, \beta > -1 \), consider the Jacobi diffusion

\[ P_t(x, y) d\mu(y) = \sum_{j=1}^{\infty} e^{-j(j+\alpha+\beta+1)} p_j^{\alpha,\beta}(x) p_j^{\alpha,\beta}(y) y^\alpha (1-y)^\beta dy \]

where \( p_j^{\alpha,\beta} \) are the associated Jacobi polynomials of degree \( j \).
Figure 3: The left figure shows a sampling from a stationary non-colliding process generated by the squared radial Ornstein-Uhlenbeck process of size $n = 20$. At the right we intersect the trajectories at multiple times $t_m$.

On $[0, 1]$, where $p_j^{(\alpha, \beta)}(x)$ is the polynomial of degree $j$ with positive leading coefficient satisfying

$$
\int_0^1 p_j^{(\alpha, \beta)}(x)p_k^{(\alpha, \beta)}(x)x^\alpha(1-x)^\beta \, dx = \delta_{jk}.
$$

Also in this case, the recurrence coefficient are explicit. Without giving them we mention that it can easily be computed that

$$a_{n+k} \to \frac{1}{4}, \quad b_{n+k} \to 1/2.
$$

In fact, this result is true for any measure $w(x)\, dx$ on $[0, 1]$ with positive weight $w(x) > 0$ (and even more general, the Denisov-Rakhmanov Theorem [43, Th. 1.4.2] says that it holds for any general measure for which the essential support is $[0, 1]$ and for which the density of the absolutely continuous part is strictly positive on $(0, 1)$).

In this case the $\lambda_j = j(j + \alpha + \beta + 1)$ is quadratic. For that reason we will consider times $t_j = n(\alpha + \beta + 2)\tau_j$ for some fixed $\tau_j$’s, so that we have

$$\kappa_n t_j(\lambda_{n+k} - \lambda_{n+\ell}) = \tau_j(k - \ell),$$

with $\kappa_n = \frac{1}{n(\alpha+\beta+2)}$ and hence both conditions in Theorem 3.1 are satisfied with $a = 1/4$ and $b = 1/2$.

The three examples above can also be obtained from stochastic evolution for matrices. See [18, 19, 32] for more details.

The last three example are continuous in time and space. The next examples are concerned with a discrete space variable, based on birth and death processes. These are processes that model a population that can increase
or decrease by one. By tuning the birth/death rates (which may depend on the size of the population) one obtains classical orthogonal polynomials of a discrete variable. We refer to [41] for more details and background. In the \( n \)-particle construction as before we then arrive at stochastic evolution for which the classical discrete orthogonal polynomial ensembles are the invariant measures. We emphasize that there are other constructions [37] that lead to discrete orthogonal polynomial ensembles, such as the Charlier processes. Although there may be relations, these examples should not be confused with each other.

**Example 3.5 (Non-colliding Meixner Ensemble).** In the first example we start with a birth and death process on \( \{0, 1, \ldots\} \) with birth \( \mu(n + \gamma) \) and death rate \( n \), where \( n \) is the size of the population. This process has the transition function

\[
P_t(x, y) d\mu(y) = \sum_{j=0}^{\infty} e^{-jt} \frac{\mu^j(\gamma)y^j}{j!} M_j(x; \gamma, \mu) M_j(y; \gamma, \mu)(1 - \mu)\frac{\mu^y(\gamma)y}{y!}
\]

on \( \{0, 1, 2, 3, \ldots\} \). Here \((\gamma)_y\) denotes the Pochhammer symbol and \( M_j \) is the Meixner polynomial of degree \( j \).

The associated \( n \)-particle generalization appeared in [9]. We now show how the conditions of Theorem 3.1 are met.

The Meixner polynomials satisfy the following recursion

\[
xM_k(x; \gamma, \mu) = -\frac{\mu(k + \gamma)}{1 - \mu} M_{k+1}(x, \gamma, \mu) + \frac{k(1 + \mu) + \mu\gamma}{1 - \mu} M_k(x, \gamma, \mu)
\]

\[
- \frac{k}{1 - \mu} M_{k-1}(x, \gamma, \mu).
\]

Also in this case, both a recalling and normalization are needed. We define

\[
p_k(\xi) = (-1)^k \sqrt{\frac{\mu^k(\gamma)k(1 - \mu)^\gamma}{k!}} M_k(\xi; \gamma, \mu).
\]

Then the recursion turns into

\[
xp_k(\xi) = \sqrt{\frac{\mu(k + \gamma)(k + 1)}{n(1 - \mu)}} p_{k+1}(\xi) + \frac{k(1 + \mu) + \mu\gamma}{1 - \mu} p_k(\xi)
\]

\[
+ \frac{\sqrt{\mu(\gamma + k - 1)k}}{n(1 - \mu)} p_{k-1}(\xi).
\]
Now it easily follows that
\[ a^{(n)}_{n+k,n} \to \frac{\sqrt{\mu}}{1 - \mu}, \quad b^{(n)}_{n+k,n} \to \frac{1 + \mu}{1 - \mu}. \]

Also \( \lambda_j \) so we have \( \tau_j = t_j \). This shows that the conditions of Theorem 3.1 hold.

**Example 3.6** (Non-colliding Charlier). In the next example we consider a birth and death process on \( \{0, 1, \ldots\} \) with birth \( \mu \) and death rate \( n \), where \( n \) is the size of the population. This process has the transition function
\[
P_t(x, y)\,d\mu(y) = \sum_{j=0}^{\infty} e^{-jt} \frac{\mu^j}{j!} C_j(x; \mu) C_j(y; \mu) e^{-n \mu} \frac{\mu^k}{k!}
\]
for \( x, y \in \{0, 1, 2, 3, \ldots\} \), where \( C_j(x; \mu) \) is the Charlier polynomial of degree \( j \).

To apply Theorem 3.1 for the corresponding \( n \)-particles process, we recall that the recursion for the Charlier reads
\[xC_k(x; \mu) = -\mu C_{k+1}(x; \mu) + (k + \mu) C_k(x; \mu) - k C_{k-1}(x; \mu).\]

As before, we renormalize
\[ p_k(x) = (-1)^k \sqrt{\frac{\mu^k}{k!}} C_k(x; \mu), \]
which gives the new recurrence
\[ xp_k(x) = \sqrt{\mu(k + 1)} p_k(x) + (k + \mu) p_k(x) + \sqrt{\mu} p_{k-1}(x). \]

Now note that this case is special, since the \( a_k \)'s and \( b_k \)'s grow with different rates. This is a well-known feature of the Charlier polynomials. It means that there are two ways to get an interesting limit which we will treat separately.

In the first one, we shift and rescale the space variable according to \( \xi = (x - n)/\sqrt{n} \), and set \( \hat{p}_k(\xi) = n^{1/4} p_k(n + \sqrt{n} x) \). These polynomials satisfy the recurrence
\[
\hat{p}_k(\xi) = \sqrt{\frac{\mu(k + 1)}{n}} \hat{p}_{k+1}(\xi) + \frac{k - n + \mu}{\sqrt{n}} \hat{p}_k(\xi) + \sqrt{\frac{\mu k}{n}} p_{k-1}(\xi).
\]

Hence we see that
\[ a^{(n)}_{n+k,n} \to \sqrt{\mu} \quad \text{and} \quad b^{(n)}_{n+k,n} \to 0. \]
Combining this with the fact $\lambda_j = j$ we see that in this way the conditions of Theorem 3.1 are met.

In the second way we allow $\mu$ to vary with $n$ and write $\mu = \tilde{\mu}n$. Then we consider the new variable $\xi = x/n$, and set $\tilde{p}_k(\xi) = \sqrt{n}\tilde{p}_k(xn)$. Now the recurrence becomes

$$\tilde{p}_k(\xi) = \frac{\sqrt{\mu k(k+1)}}{n}\tilde{p}_{k+1}(\xi) + \frac{k(1+\mu)}{n}\tilde{p}_k(\xi) + \frac{\sqrt{\mu k}}{n}\tilde{p}_{k-1}(\xi).$$

In this case we have $a_{n+k}^{(n)} \rightarrow \sqrt{\mu}$ and $b_{n+k}^{(n)} \rightarrow 1 + \mu$.

Combining this again with the fact $\lambda_j = j$ we see that also in this way the conditions of Theorem 3.1 are met.

Finally, we want to mention that this process is different from what is usually referred to as the Charlier process [33, 38], which is non-colliding Poisson random walks starting from densely packed initial points. In that case we only allow for up jumps. The Charlier Ensemble appears there as the fixed time distribution, but not as the invariant measure.

\[\text{Example 3.7 (Non-colliding Krawtchouck).}\] In the final example we consider a birth and death process on $\{0, 1, \ldots, M\}$ with birth rate $p(M-n)$ and death rate $n(1-p)$, where $n$ is the size of the population, $p \in (0, 1)$ and $M \in \mathbb{N}$. We then have the transition function

$$P_t(x, y) d\mu(y) = \sum_{j=0}^{M} e^{-jt} \binom{M}{j} p^j (1-p)^{M-j} K_j(x; M, p) K_j(y; M, p) \binom{M}{k} p^k (1-p)^{M-k}$$

(3.2)

on $\{0, 1, 2, 3, \ldots, M\}$, where $K_j$ is the Krawtchouk polynomial of degree $j$.

In order for the $n$-particles process to make sense, we need enough available nodes for all the paths. That is, we need a $M \geq n$. In fact, when taking the limit $n \rightarrow \infty$, we will assume that $M_n$ also goes to infinity such that

$$\frac{M_n}{n} \rightarrow \gamma > 1.$$

The Krawtchouk polynomial satisfy the recurrence

$$x K_k(x; M, p) = p(M-k)K_{k+1}(x; M, p) - (p(M-k) + k(1-p)) K_k(x; M, p)$$
In this case we define the rescaled and normalized polynomials

\[
p_k(x) = (-1)^k \binom{M}{k}^{1/2} \left( \frac{p}{1-p} \right)^{k/2} (-1)^k K_k(x; M, p),
\]

and for these polynomials we get the recursion

\[
x p_k(x) = \sqrt{p(1-p)} \left( \frac{1}{k+1} \right) p_{k+1}(x) + \frac{pM - 2pk + k}{n} p_k(x) + \sqrt{p(1-p)} \left( \frac{1}{k+1} \right) p_{k-1}(x).
\]

Hence in this model we have, with \( M/n \rightarrow \gamma \),

\[
a_{n+k,n} \rightarrow \sqrt{p(1-p)\gamma}, \quad b_{n+k,n}^{(n)} \rightarrow p\gamma - 2p + 1,
\]

and, again \( \lambda_j = j \), so that the conditions of Theorem 3.1 are satisfied.

The invariant measure for the \( n \)-particle process is the Krawtchouk ensemble. This ensemble also appears in random domino tilings of an Aztec diamond [25]. However, the multi-time processes here is different from the extended Krawtchouk Ensemble in [25]. It is also different from the process introduced in [33] for which the single time distribution is a Krwatchouk Ensembles.

3.2 Non-stationary example

We now consider the same construction ideas as the non-colliding Ornstein-Uhlenbeck process of Example 3.2, but instead of having the invariant measure as initial condition, we take the initial points random from a Unitary Ensemble. That is, we take \( x_j \) random from the probability measure on \( \mathbb{R}^n \) proportional to

\[
\prod_{1 \leq i < j \leq n} (x_i - x_j)^2 e^{-n \sum_{j=1}^{n} V(x_j)} dx_1 \cdots dx_n,
\]

where \( V \) is a polynomial of even degree and positive leading coefficient (so that the above measure is indeed of finite mass). Then if we start the non-colliding Ornstein-Uhlenbeck process from these initial points and look at the positions \( \{x_{j,m}\}_{j=1,m=1}^{n,N} \) at times

\[0 = t_1 < \ldots < t_N,\]

33
then we find that the following joint probability for these locations is proportional to
\[
\det \left( x_{j,k}^{j-1} \right)_{j,k=1}^n \prod_{m=1}^N \det \left( T_m(x_{j,m}, x_{k,m+1}) \right)_{j,k=1}^n \times \det \left( x_{j,k}^{j-1} \right)_{j,k=1}^n \prod_{m=1}^N \prod_{j=1}^n d\mu_{m}(x_{j,m}), \quad (3.3)
\]
where, with \( \Delta_m = e^{-t_{m+1}^{(n)} - t_{m}^{(n)}} \),
\[
T_m(x, y) = (2\pi)^{-1/2} \exp \left( \frac{-n\Delta_m^2 (x^2 + y^2) + n\Delta_m xy}{1 - \Delta_m^2} \right) = \sum_{j=0}^{\infty} e^{-jt} H_j(\sqrt{n}x)H_j(\sqrt{n}y)
\]
and
\[
d\mu_{m}(x) = \begin{cases} 
    e^{-nV(x)}dx, & m = 1 \\
    e^{-nx^2/2}dx, & m = 2, \ldots, N.
\end{cases}
\]
(Note that we have rescaled space immediately).

The functions in the determinant are not in the right form, as Assumption 2.1 is not yet satisfied. Hence the first thing to do is to rewrite the probability density. We start by defining \( p_{j,n} \) to be the normalized orthogonal polynomial (with positive leading coefficient) with respect to \( e^{-nV(x)}dx \).

Now set
\[
\phi_{j,1}(x) = p_{j-1,n}(x).
\]
To define the \( \phi_{j,m} \)'s we first expand \( p_{j-1,n} \) in terms of Hermite functions
\[
p_{j,n}(x) = \sum_{k=0}^{j} c_{j,k} H_k(x),
\]
where \( H_n(x) \) are the normalized Hermite polynomials. We then define
\[
\psi_{j,N}(x) = \sum_{k=0}^{j-1} c_{j,k} e^{kt_N} H_k(x).
\]
It is then straightforward that
\[
\psi_{j,m}(x) = T_m^* \cdots T_{N-1}^* \psi_{j,N}(x) = \sum_{k=0}^{j-1} c_{j,k} e^{kt_m} H_k(x).
\]
Figure 4: The non-colliding Ornstein-Uhlenbeck process started from arbitrary points at \( t = 0 \). In the example of Section 3.2 we take those initial points randomly from a Unitary Ensemble.

Hence, we also have \( \phi_{j,1} = \psi_{j,1} = p_{j-1,n}(x) \) and the biorthogonality condition is satisfied. In the following lemma we show that these indeed are biorthogonal families and that they satisfy a recursion.

**Lemma 3.8.** The \( \phi_{j,m} \) satisfy a recurrence relation

\[
x \begin{pmatrix} \phi_{1,m}(x) \\ \phi_{2,m}(x) \\ \vdots \\ \phi_{j,m}(x) \\ \vdots \end{pmatrix} = \mathbb{J}_m \begin{pmatrix} \phi_{1,m}(x) \\ \phi_{2,m}(x) \\ \vdots \\ \phi_{j,m}(x) \\ \vdots \end{pmatrix}
\]

with

\[
(\mathbb{J})_{j,k} = \begin{cases} e^{-tm}(\mathcal{J})_{j,k}, & \text{if } j > k, \\
e^{-tm}(\mathcal{J})_{j,k} + 2 \sinh tm(V'(\mathcal{J}))_{j,k}, & \text{if } j \leq k, \end{cases}
\]

where \( \mathcal{J} \) is the Jacobi matrix associated to the polynomials \( p_j \).

**Proof.** For \( m = 1 \) the statement is trivial since then \( \psi_{j,1} = \phi_{j,1} = p_{j-1,n} \) and the the recurrence matrix is \( \mathcal{J} \) by definition, which is also the result when we substitute \( t_m = 0 \) in the statement.

So it remains to deal with the case \( m > 1 \). We first claim that

\[
p'_{j-1,n}(x) = n \sum_{k<j} (V'(\mathcal{J}))_{k,j} p_{k-1,n}(x).
\]

To see this, we note that \( p'_{j-1,n}(x) \) is a polynomial of degree \( j - 2 \) and hence it can be expanded in terms of the polynomials \( p_{k-1,n} \) for \( k = 0, \ldots, j - 1 \). That the coefficients in the expansion are indeed as stated follows from an integration by parts.
\[
\int p_{k-1,n}(x)p'_{j-1,n}(x)e^{-nV(x)}dx = n \int V(x)p_{k-1,n}(x)p_{j-1,n}(x)e^{-nV(x)}dx
\]
\[
- \int p'_{k-1,n}(x)p_{j-1,n}(x)e^{-nV(x)}dx = (V'(J))_{k,j}, \quad (3.5)
\]

where the second integral in the middle part vanishes by orthogonality and the fact that \(k < j\).

Then, for \(m > 1\), we have

\[
\phi_{j,m}(x) = \frac{1}{\sqrt{2\pi(1 - e^{-2t_m})}} \int p_{j-1,n}(y)e^{-n\left(V(y)+\frac{e^{-2t_m}(x^2+y^2)-2e^{-t_m}xy}{2(1-e^{-2t_m})}\right)}dy.
\]

Hence, by integration by parts,

\[
x\phi_{j,m}(x) = -\frac{2 \sinh t_m}{n} e^{-\frac{e^{-2t_m}x^2}{2(1-e^{-2t_m})}} \int p_{j-1,n}(y)e^{-n\left(V(y)+\frac{e^{-2t_m}y^2}{2(1-e^{-2t_m})}\right)} \frac{\partial}{\partial y} e^{-\frac{e^{-t_m}xy}{2\sinh t_m}} dy
\]
\[
= 2 \sinh t_m \int \left(-p'_{j-1,n}(y)/n + p_{j-1,n}(y)V'(y) + p_{j-1,n}(y)\frac{e^{-t_m}y}{2\sinh t_m}\right)
\]
\[
\times e^{-n\left(V(y)+\frac{e^{-2t_m}(x^2+y^2)+2e^{-t_m}xy}{2(1-e^{-2t_m})}\right)} dy \quad (3.6)
\]

The statement now follows by a rewriting of the latter using the recurrence matrix \(J\) and using (3.4).

From Lemma 3.8 it in particular follows that if the recurrence coefficients for the orthogonal polynomials have the required asymptotic behavior, then also the recurrence coefficients for \(\phi_{j,m}\) have the required behavior and Theorems 2.3 and 2.7 apply.

**Proposition 3.9.** If the recurrence coefficients \(a_{k,n}\) and \(b_{k,n}\) for \(p_{k,n}\) satisfy

\[
a_{n+k,n} \to a, \quad b_{n+k,n} \to b,
\]

as \(n \to \infty\), then Theorem 2.2 applies where

\[
a^{(m)}(z) = 2 \sinh(t_m)(V'(az+b+a/z))_+ + e^{-t_m}(az+b+a/z),
\]

where \((V'(az+b+a/z))_+\) is the part of the Laurent polynomial \(V'(az+b+a/z)\) containing the non-negative powers.

Moreover, Theorem 2.6 also applies with

\[
\sum_j a_j(t)z^j = 2 \sinh(t)(V'(az+b+a/z))_+ + e^{-t}(az+b+a/z).
\]
The conditions of the latter proposition are met, when the polynomial $V$ is such that the zeros of $p_n$ accumulate on a single interval \[15\]. This happens for example when $V$ is convex.

Finally, we note that the above model is a special case of the Hermitian multi-matrix model. In the present setting the limiting distribution of points at a given time $t$ can also be computed using the recurrence coefficients, as was done in \[17\] for the special case where $V$ is an even quartic. This even leads to a vector equilibrium problem for the limiting distribution.

3.3 Lozenge tilings of a hexagon

The last example that we will treat is that of lozenge tilings of an $abc$-hexagon. See Figure 5. This well-studied model can also be viewed as a model of discrete non-intersecting paths. It was proved in \[39\] (in a more general context) that the height function associated to the paths indeed has Gaussian Free Field fluctuations. We will show here that it also follows from our general results. We first give the two equivalent descriptions of the model in terms of tilings and in terms of non-intersecting paths, starting with the latter.

Fix $a, b, c \in \mathbb{N}$ and without loss of generality we assume that $b \leq c$. Then we consider a collection $\tilde{\gamma}$ of $c$ zig-zag paths $\gamma_j : \{0, 1, \ldots, b + c\} \rightarrow \mathbb{Z}$ for $j = 1, \ldots, a$ such that

Figure 5: A lozenge tiling of an $abc$-hexagon (l) and the equivalent representation in terms of non-intersecting paths (r).
1. They start $\gamma(0) = 2j - 1$ and end at $\gamma(b + c) = c - b + 2j - 1$ for $j = 1, \ldots, a$.

2. At each step by one to the right, the path goes up or down by one, i.e., $\gamma_j(k + 1) = \gamma_j(k) \pm 1$.

3. The paths never cross $\gamma_j(k) < \gamma_{j+1}(k)$.

Note that due to the conditions on the starting and endpoints, each path will consist of $b$ down steps and $c$ up steps. We then take the uniform measure on all such $\gamma$. This is equivalent to say that we consider a random walkers with given starting and ending points conditioned never to intersect.

A different representation is that of lozenge tiling of the hexagon. Indeed, if we take an $abc$-hexagon with corners $(0, 0)$, $(0, 2a)$, $(c, 2a + c)$, $(b + c, 2a + c - b)$, $(b + c, c - b)$ and $(b, -b)$ and tile this hexagon with lozenges of type I, type II, and type III.

To make the connection with the above path model, we associate to each tiling of the hexagon a collection of paths by drawing a down step on a lozenge of type I and an up step on a type III lozenge going through the centers of the lozenges. That is,

To make the connection with the above path model, we associate to each tiling of the hexagon a collection of paths by drawing a down step on a lozenge of type I and an up step on a type III lozenge going through the centers of the lozenges. That is,

It is then easy to see that this indeed defines a collection of zig-zag paths that do not intersect and start and end from the given points. Moreover, by taking the uniform measure on all possible tiling, we obtain the uniform measure on all zig-zag paths.

In [21, 26] it was proved that the locations of the paths $\{(k, \gamma_j(k))\}_{k=1, j=1}^{b+c-1, a}$ form a determinantal point process with a kernel constructed out of the Hahn polynomials. We recall that the Hahn polynomials $q_{k,M}^{(\alpha, \beta)}$ are the orthonormal polynomials with respect to the weight

$$w^{(\alpha, \beta)}_M(x) = \frac{1}{x!(x + \alpha)!(M + \beta - x)!(M - x)!}$$

on $\{0, 1, \ldots, M\}$, i.e.

$$\sum_{x=0}^{M} q_{k,M}^{(\alpha, \beta)}(x)q_{\ell,M}^{(\alpha, \beta)}(x)w_{N}^{(\alpha, \beta)} = \delta_{k\ell}.$$
They have the explicit representation

\[
q_{k,M}^{(\alpha,\beta)} = \frac{(-\alpha - M - \beta k(-M)_k)}{k!d_{k,M}^{(\alpha,\beta)}} 3F_2 \left( \begin{array}{c} -k, k - 2M - \alpha - \beta - 1, -x \\ -M - \beta, -M \end{array} \right) ; 1
\]

with

\[
d_{k,M}^{(\alpha,\beta)} = \frac{(\alpha + \beta + M + 1 - k)_{M+1}}{(\alpha + \beta + 2kM + 1 - 2k)k!(\beta + M - k)!(\alpha + M - k)!(M - k)!},
\]

and \((\alpha)_M = \alpha(\alpha + 1) \cdots (\alpha + M - 1)\) denotes the usual Pochhammer symbol.

From [29 §9.5] it follows that the normalized Hahn polynomials have the recurrence

\[
x q_{k,M}^{(\alpha,\beta)}(x) = a_{k+1} q_{k+1,M}^{(\alpha,\beta)}(x) + b_k q_{k,M}^{(\alpha,\beta)}(x) + a_k q_{k-1,M}^{(\alpha,\beta)}(x), \quad (3.7)
\]

where

\[
a_k = \sqrt{\frac{(M - k + 1)k(M - k + 1 + \alpha)(M - k + 1 + \beta)(M - k + 1 + \alpha + \beta)(2M - k + 2 + \alpha + \beta)}{(1 + 2M - 2k + \alpha + \beta)(2 + 2M - 2k + \alpha + \beta)^2(3 + 2M - 2k + \alpha + \beta)}},
\]

and

\[
b_k = \frac{(2M + \alpha + \beta + k - 1)(M + \beta - k)(M - k)}{(2M - 2k + \alpha + \beta)(2M - 2k + \alpha + \beta + 1)}
\]

\[+ \frac{k(2M + \alpha + \beta + 1 - k)(M - k + 1)}{(2M - 2k + \alpha + \beta + 2)(2M - 2k + \alpha + \beta + 1)} \quad (3.9)
\]

Now we come back to the tiling process. We first need some notations in which we follow [26]. Set \(\alpha_r = |c - r|\), \(\beta_r = |b - r|\), \(L_r = b - b_r\) and

\[
M_r = \begin{cases} r + a - 1, & 0 \leq r \leq b, \\ b + a - 1, & b \leq r \leq c, \\ a + b + c - 1 - r, & c \leq r \leq a + c. \end{cases}
\]

Then, as shown in [21 26], the locations of the paths \(\{(m, \gamma_j(m))\}\) (or, equivalently, the centers of the tiles of type II) form a determinantal point process on \(\{0, 1, \ldots, B + C\} \times \mathbb{Z}\) with kernel

\[
K_a(r, L_r + 2x + 1, s, L_s + 2y + 1) = \begin{cases} \sum_{k=0}^{a-1} \sqrt{\frac{(a + s - 1 - k)![(a + b + c - r - 1 - k)]!}{(a + r - 1 - k)![(a + b + c - s - 1 - k)]!}} q_{k,M_r}^{(\alpha_r,\beta_r)}(x) q_{k,M_s}^{(\alpha_s,\beta_s)}(y), & r \leq s, \\ -\sum_{k=a}^{-1} \sqrt{\frac{(a + s - 1 - k)![(a + b + c - r - 1 - k)]!}{(a + r - 1 - k)![(a + b + c - s - 1 - k)]!}} q_{k,M_r}^{(\alpha_r,\beta_r)}(x) q_{k,M_s}^{(\alpha_s,\beta_s)}(y), & r > s. \end{cases} \quad (3.10)
\]

39
The question of interest is what happens with the system as the hexagon becomes large. That is, we introduce a big parameter $n$ and scale $a, b$ and $c$ such that

$$a/n \to 1, \quad b/n \to B > 0, \quad c/n \to C > 0.$$ 

Then we take $\rho_m \in (0, B + C)$ for $m = 1, \ldots, N$ and set $r_r = \lfloor n\rho_r \rfloor$ where $\lfloor \cdot \rfloor$ denotes the integer part. We also rescale the process along the vertical axis by $n$ (hence we replace $x$ by $[nx]$).

We then set $p_{j,m}(x) = \theta_{j,M_{j,m}}([nx])$ and

$$c_{j,m} = \sqrt{\frac{(a + b + c - r_m - 1 - j)!}{(a + r_m - 1 - j)!}},$$

and consider the probability measure (2.1) with $\phi_{j,m} = c_{j,m}p_{j-1,m}$ and $\psi_{j,m} = 1/c_{j,m}p_{j-1,m}$ as in (2.10) (with $T_m(x,y) = \sum_{j=0}^{\infty} c_{j,m+1}/c_{j,m}p_{j,m}(x)p_{j,m+1}(y)$).

Denote the recurrence coefficients for $p_{j,m}$ by $a_{j,m}^{(n)}$ and $b_{j,m}^{(n)}$. Then, from (3.8), (3.9) and the choice of the parameters is not hard to show that there exists functions $F_1$ and $F_2$ as $n \to \infty$,

$$a_{n+k,m}^{(n)} \to F_1(\rho_m; B, C), \quad b_{n+k,m}^{(n)} \to F_2(\rho_m; B, C),$$

for any $k \in \mathbb{N}$. In other words, condition (2.18) is satisfied. Moreover, we also we easily verify (2.19) and find

$$\lim_{n \to \infty} \frac{c_{l,m}}{c_{k,m}} = e^{\tau_m (k-l)}, \quad \text{with} \quad \tau_m = \frac{1}{2} \ln \frac{1 + B + C - \rho_m}{1 + \rho_m}.$$

Hence we see that Theorem 2.4 applies. Also note that after rescaling with $n$ the hexagon will always be contained in a fixed compact set for every $n$, hence also Corollary 2.5 applies.

Similarly, in the same way one can verify that Corollary 2.8, Theorem 2.9 and Theorem 2.10 apply. We leave the precise statement to the reader.

4 From linear statistics to the recurrence matrices

In this section we show how the moments and cumulants of the linear statistics are connected to the matrices $J_m$.

The determinantal structure of the process means that we can express the moments of linear statistics in terms of the kernel $K_{n,N}$ (2.8). Indeed,
Figure 6: A sampling of a random tiling of a large regular hexagon (l) and the alternative representation in terms of non-intersecting paths (r). The disorded regime, circle inside the hexgon, and the frozen corners are clearly visible.

It is standard that from (2.7) and some computations one can show

\[
\mathbb{E}X_n(f) = \sum_{m=1}^{N} \int f(m, x)K_{n,N}(m, x, m, x)d\mu_m(x),
\]

implying that \(K_{n,N}(m, x, m, x)\) is the mean density. Moreover,

\[
\text{Var} X_n(f) = \sum_{m=1}^{N} \int f(m, x)^2K_{n,N}(m, x, m, x)d\mu_m(x)
\]

\[
- \sum_{m_1, m_2=1}^{N} \iint f(m_1, x_1)f(m_2, x_2)K_{n,N}(x_1, m_1, x_2, m_2)K_{n,N}(x_2, m_2, x_1, m_1)d\mu_{m_1}(x_1)d\mu_{m_2}(x_2).
\]

(4.1)

and similar expressions hold for the higher terms.

Although we use these expressions in the proofs of Theorem 2.5 and 2.9, the general strategy in this paper is based on a different approach. The key identity is the following lemma, connecting the moments to the recurrence matrices \(J_m\).

\[\text{These figures are produced using a code that was kindly provided to the author by Leonid Petrov.}\]
Lemma 4.1. Suppose that \( f(m, x) \) is a polynomial in \( x \) and \( \mathbb{J}_m \) is bounded for \( m = 1, \ldots, N \), then
\[
\mathbb{E}\left[e^{\lambda X_n(f)}\right] = \det\left(\left(e^{\lambda f(1,J_1)}e^{\lambda f(2,J_2)} \cdots e^{\lambda f(N,J_N)}\right)_{i,j}\right)^n_{i,j=1}.
\] (4.2)

In case one of the \( \mathbb{J}_m \) is an unbounded matrix, the equality is understood as an equality between formal power series by expanding each exponential. More precisely, with \( R_M(x) = \sum_{k=0}^{M} x^k / k! \) consider the expansion
\[
\det\left(\left(R_M(\lambda f(1,J_1))R_M(\lambda f(2,J_2)) \cdots R_M(\lambda f(N,J_N))\right)_{i,j}\right)^n_{i,j=1} = \sum_{k=0}^{\infty} D_{k,M}(f) \frac{\lambda^k}{k!},
\] (4.3)
then we have \( \mathbb{E}\left[(X_n(f))^k\right] = D_{k,M}(f) \), for \( k \leq M \).

Remark 4.1. Before we come to the proof we note that since the \( \mathbb{J}_m \)'s are banded matrices and \( f \) is a polynomial, the product of the matrices \( R_m(f(\mathbb{J}_m, m)) \) is well-defined so that the determinant at the left-hand side of (4.3) makes sense.

Proof. It is enough to prove (4.3). In case all \( \mathbb{J}_m \) are bounded we then obtain (4.2) by taking the limit \( M \to \infty \) in a straightforward way.

We first note that the first \( M + 1 \) terms of the (formal) expansions
\[
\mathbb{E}\left[e^{\lambda X_n(f)}\right] = \mathbb{E}\left[\prod_{j=1}^{n,N} e^{\lambda f(m,x_{m,j})}\right]
\]
and
\[
\mathbb{E}\left[\prod_{j=1}^{n,N} R_M(\lambda f(m,x_{m,j}))\right]
\]
are equal. To prove the lemma it thus suffices to prove that the last expectation equals the left-hand side of (4.3). To this end, we note
\[
\mathbb{E}\left[\prod_{j=1}^{n,N} R_M(\lambda f(m,x_{m,j}))\right] = \frac{1}{(n!)^N} \int \cdots \int \left(\prod_{j=1}^{n,N} R_M(\lambda f(m,x_{m,j}))\right) \det(\phi_{j,1}(x_{1,k}))^n_{j,k=1} \times \prod_{m=1}^{N-1} \det(T_m(x_{m,i}, x_{m+1,j}))^n_{i,j=1} \det(\psi_{j,N}(x_{N,k}))^n_{j,k=1} \prod_{m=1}^{N} \prod_{j=1}^{n} d\mu_m(x_{m,j})
\]
\[
= \frac{1}{(n!)^N} \int \cdots \int \det (\phi_{s,1}(x_{1,k}))_{j,k=1}^n \prod_{m=1}^{N-1} \det (R_M(\lambda f(m, x_{m,i}))T_m(x_{m,i}, x_{m+1,j}))_{i,j=1}^n \\
\times \det (R_M(\lambda f(N, x_{N,k}))\psi_j,N(x_{N,k}))_{j,k=1}^n \prod_{m=1}^N \prod_{j=1}^n d\mu_m(x_{m,j}),
\]

For convenience we set some notation \( A_m = R_M(\lambda f(m, J_m)) \). Now the statement is a special case (where \( s_j = j \)) of the more general claim

\[
\frac{1}{(n!)^N} \int \cdots \int \det (\phi_{s,1}(x_{1,k}))_{j,k=1}^n \prod_{m=1}^{N-1} \det (R_M(\lambda f(m, x_{m,i}))T_m(x_{m,i}, x_{m+1,j}))_{i,j=1}^n \\
\times \det (R_M(\lambda f(N, x_{N,k}))\psi_j,N(x_{N,k}))_{j,k=1}^n \prod_{m=1}^N \prod_{j=1}^n d\mu_m(x_{m,j})
= \det (\prod_{j=1}^n j)_{i,j=1}^n, \quad (4.4)
\]

for any \( s_1 < \ldots < s_n \).

The proof of (4.4) goes by induction to \( N \).

The case of \( N = 1 \) is a direct consequence of Andreief’s identity in (2.3)

\[
\frac{1}{n!} \int \cdots \int \det (\phi_{s,1}(x_{1,k}))_{j,k=1}^n \det (R_M(\lambda f(1, x_{1,k}))\psi_{s,1}(x_{1,k}))_{j,k=1}^n \prod_{j=1}^n d\mu_1(x_{1,j})
= \det \left( \int R_M(\lambda f(1, x))\phi_{s,1}(x)\psi_{s,1}(x)d\mu_1(x) \right)_{i,j=1}^n = \det (A_{s_1,s_1})_{i,j=1}^n.
\]

For \( N > 1 \) we use Andreief’s identity to write

\[
\frac{1}{n!} \int \cdots \int \det (\phi_{s,1}(x_{1,k}))_{j,k=1}^n \det (R_M(\lambda f(x_{1,i}, 1))T_1(x_{1,i}, x_{2,j}))_{i,j=1}^n \prod_{j=1}^n d\mu_1(x_{1,j})
= \det \left( \int T_1(x, x_{2,i})R_M(\lambda f(x, 1))\phi_{s,1,N}(x)d\mu_1(x) \right). \quad (4.5)
\]

By using the recurrence and the fact that

\[
\int T_1(x, x_{2,i})\phi_{k,1}(x)d\mu_1(x) = \phi_{k,2}(x_{2,i})
\]

we find that the right-hand side of (4.5) can be written as

\[
\det \left( \sum_k A_{s,k}\phi_{k,2}(x_{2,i}) \right)_{i,j=1}^n = \sum_{l_1 < l_2 < \ldots < l_n} \det (A_{s,l_1})_{i,j=1}^n \det (\phi_{l_1,2}(x_{2,i}))_{i,j=1}^n
\]

43
where we used Cauchy-Binet in the last step. By inserting the latter with (4.5) back into the left-hand side of (4.4) and using the induction hypothesis we find that the left-hand side of (4.4) can be written as
\[
\sum_{l_1 < l_2 < \ldots < l_n} \det \left( (A_{1})_{s_k, l_j} \right)_{j,k=1}^{n} \det \left( (A_2 \ldots A_N)_{l_j, s_i} \right)_{i,j=1}^{n} = \det \left( (A_1 \ldots A_N)_{s_i, s_k} \right)_{i,k=1}^{n},
\]
where we used Cauchy-Binet in the last step again. This proves the claim in (4.4) and hence the statement. □

This lemma also has a convenient consequence. Since all \( \mathbb{J}_m \) are banded, each entry
\[
(R_M(\lambda f(1, \mathbb{J}_1))R_M(\lambda f(2, \mathbb{J}_2)) \ldots R_M(\lambda f(N, \mathbb{J}_N)))_{i,j}
\]
for \( i, j = 1, \ldots, n \) only depends on some entries of the individual \( \mathbb{J}_m \)'s. By writing out the matrix product it is not hard to see that these entries do not depend on any \( (\mathbb{J}_m)_{rs} \) for \( m = 1, \ldots, N \) and \( r, s > S \) for some sufficiently large \( S \). Hence if we define the cut-offs
\[
(\mathbb{J}_{m,S})_{j,k} = \begin{cases} 
(\mathbb{J}_m)_{j,k} & j, k \leq S \\
0 & \text{otherwise,}
\end{cases}
\]
and expand
\[
det \left( (e^{\lambda f(1, \mathbb{J}_{m,S})} e^{\lambda f(2, \mathbb{J}_{2,S})} \ldots e^{\lambda f(N, \mathbb{J}_{N,S})}) \right)_{i,j=1}^{n} = \sum_{k=0}^{\infty} \frac{\lambda^k}{k!} \tilde{D}_{k,S}(f), \tag{4.6}
\]
then for each \( k \in \mathbb{N} \) we have \( \mathbb{E} \left[ (X_n(f))^k \right] = \tilde{D}_{k,S}(f) \) for sufficient large \( S \) (which may depend on \( k \)). The benefit is that the matrix in the determinant consists of a product of bounded operators and the series is convergent. Hence we do not have to worry about formal series and this will be convenient for technical reasons.

Instead of the moments, it will be more convenient to work with the cumulants \( C_k(X_n(f)) \). These are special combinations of the linear statistic, determined by the (formal) generating function
\[
\log \mathbb{E} [\lambda X_n(f)] = \sum_{k=1}^{\infty} \frac{\lambda^k}{k!} C_k(X_n(f)). \tag{4.7}
\]
Note that $C_1(X_n(f)) = \mathbb{E}X_n(f)$ and $C_2(X_n(f)) = \text{Var} X(f)$. The $k$-th cumulant can be expressed in terms of the first $k$ moments and vice versa. Since the first terms in the expansion on the right-hand side of (4.6) are the moments, we can take the logarithm at both sides and immediately obtain the following lemma.

**Lemma 4.2.** Let $C_{k,S}(f)$ be the coefficients in the series

$$\log \det \left( \left( e^{\lambda f(1, J_{m,S})} e^{\lambda f(2, J_{m,S})} \ldots e^{\lambda f(N, J_{m,S})} \right)_{i,j=1}^{n} \right) = \sum_{k=0}^{\infty} \frac{\lambda^k}{k!} C_{k,S}(f),$$

then $C_k(X_n(f)) = C_k,S(f)$ for sufficiently large $S$.

Using this representation, we will give useful expressions for all the cumulants. We will do this in the next section in a more general setup.

## 5 Expansions of Fredholm determinant

In this section we will look at the expansion given in Lemma 4.2 where we replace the $f(m, J_{m,S})$’s in the determinant by general banded and bounded operators $A_m$.

### 5.1 Preliminaries

We start by recalling traces and determinants for trace class operators. We refer to [23, 42] for more details.

For a compact operator $A$ on a separable Hilbert space $\mathcal{H}$ we define the singular values

$$\sigma_1(A) \geq \sigma_2(A) \geq \sigma_3(A) \geq \ldots > 0,$$

as the square roots of the eigenvalues of the self-adjoint compact operators $A^*A$. The space of trace class operators is then defined as the Banach space

$$\mathcal{B}_1(\mathcal{H}) = \{ A \mid \sum_{k=1}^{\infty} \sigma_k(A) < \infty \},$$

equipped with the trace norm

$$\|A\|_1 = \sum_{k=1}^{\infty} \sigma_k(A).$$
The space of Hilbert-Schmidt operators is then defined as the Hilbert space
\[ B_2(\mathcal{H}) = \{ A \mid \sum_{k=1}^{\infty} \sigma_k(A)^2 < \infty \}, \]
equipped with the Hilbert-Schmidt norm
\[ \| A \|_2 = \left( \sum_{k=1}^{\infty} \sigma_k(A)^2 \right)^{1/2}. \]
We also denote the operator norm by \( \| A \|_\infty \) and the space of bounded operators by \( B_\infty(\mathcal{H}) \).

The following identities are standard. For any \( A \in B_\infty(\mathcal{H}) \) and \( B \in B_1(\mathcal{H}) \) we have
\[ \| AB \|_1, \| BA \|_1 \leq \| A \|_\infty \| B \|_1. \]
Similarly, for any \( A \in B_\infty(\mathcal{H}) \) and \( B \in B_2(\mathcal{H}) \) we have
\[ \| AB \|_2, \| BA \|_2 \leq \| A \|_\infty \| B \|_2. \]
For any \( A, B \in B_2(\mathcal{H}) \) we have
\[ \| AB \|_1 \leq \| A \|_2 \| B \|_2. \]
The trace class operators \( B_1(\mathcal{H}) \) are precisely the operators for which we can define the trace, denote by \( \text{Tr} A \), by naturally extending the trace for finite rank operators. We note that
\[ | \text{Tr} A | = \| A \|_1. \]
For any trace class operator \( A \in B_1(\mathcal{H}) \) we can also define the operator determinant \( \det(I + A) \) by natural extension from the finite rank operators. Here we note that
\[ | \det(I + A) - \det(I + B) | \leq \| A - B \|_1 \exp(\| A \|_1 + \| B \|_1 + 1). \]
A particular relation between the trace and the determinant that we will use is the following
\[ \log \det(I + A) = \sum_{j=1}^{\infty} \frac{(-1)^{j+1}}{j} \text{Tr} A^j, \quad (5.1) \]
valid for any \( A \in B_1(\mathcal{H}) \) for which \( \| A \|_\infty < 1 \) (ensuring the convergence of the right-hand side).
5.2 A cumulant-type expansion

Let \( A_1, \ldots, A_N \) be bounded operator on \( \ell_2(\mathbb{N}) \) (in the coming analysis we will identity bounded operators on \( \ell_2(\mathbb{N}) \) with their semi-infinite matrix representations with respect to the canonical basis). We will also use the notation \( P_n \) for the projection operators on \( \ell_2(\mathbb{N}) \) defined by

\[
P_n: (x_1, x_2, \ldots) \mapsto (x_1, \ldots, x_n, 0, 0, \ldots),
\]

and \( Q_n = I - P_n \). Then

\[
\det \left( I + P_n \left( e^{\lambda A_1}e^{\lambda A_2} \cdots e^{\lambda A_N} - I \right) P_n \right),
\]

is a well-defined and entire function of \( \lambda \). By taking \( A = e^{\lambda A_1}e^{\lambda A_2} \cdots e^{\lambda A_N} - I \) in (5.1) for sufficiently small \( \lambda \) we define \( C_k^{(n)}(A_1, \ldots, A_N) \) by

\[
\log \det \left( I + P_n \left( e^{\lambda A_1}e^{\lambda A_2} \cdots e^{\lambda A_N} - I \right) P_n \right) = \sum_{m=1}^{\infty} \lambda^k C_k^{(n)}(A_1, \ldots, A_N),
\]

which is valid for small \( \lambda \). In Lemma 4.2 we have shown that the relation between the cumulant \( C_k(X_n(f)) \) and the general coefficient \( C_k^{(n)}(A_1, \ldots, A_N) \) is given by

\[
C_k(X_n(f)) = C_k^{(n)}(f(1, \mathbb{J}_1, s), \ldots, f(N, \mathbb{J}_N, s)),
\]

for sufficiently large \( S \). We will use this connection only in Section 6 when we give the proofs of the main results. In this section we focus on general properties of \( C_k^{(n)}(A_1, \ldots, A_N) \). To start with, an easy consequence of the above is the following.

**Lemma 5.1.** We have

\[
C_k^{(n)}(A_1, \ldots, A_N) = \frac{1}{2\pi i} \oint_{|z|=\rho} \text{Tr} \log \left( I + P_n \left( e^{\lambda A_1}e^{\lambda A_2} \cdots e^{\lambda A_N} - I \right) P_n \right) \frac{d\lambda}{\lambda^{k+1}},
\]

where \( 0 < \rho < (2 \sum_{j=1}^{N} \|A_j\|_{\infty})^{-1} \).

**Proof.** The only remaining is the choice of \( \rho \). To this end, we note that

\[
\left\| P_n \left( e^{\lambda A_1}e^{\lambda A_2} \cdots e^{\lambda A_N} - I \right) P_n \right\|_{\infty} \leq |\lambda| \sum_{j=1}^{N} \|A_j\|_{\infty} \exp \left( |\lambda| \sum_{j=1}^{N} \|A_j\|_{\infty} \right),
\]

and that \( \frac{1}{2} e^{\frac{1}{2}} < 1 \). Hence the integrand at the right-hand side of (5.4) is well-defined and analytic for \( |\lambda| < \rho \). This proves the statement. \( \square \)
Lemma 5.2. We have

\[ C_k^{(n)}(A_1, \ldots, A_N) = \sum_{j=1}^{k} \frac{(-1)^{j+1}}{j} \sum_{\ell_1 + \ldots + \ell_j = k} \sum_{(r_{s,v})_{s=1}^{N} \in R_{\ell_1, \ldots, \ell_j}} \frac{\operatorname{Tr} \prod_{s=1}^{j} (P_n A_1^{r_{s,1}} \ldots A_N^{r_{s,N}} P_n)}{r_{1,1}! \ldots r_{1,N}! r_{2,1}! \ldots r_{2,N}! \ldots r_{j,1}! \ldots r_{j,N}!} \]  

(5.5)

where

\[ R_{\ell_1, \ldots, \ell_j} = \left\{ (r_{s,v})_{s=1}^{N} | r_{s,v} \in \{0, 1, 2, \ldots\}, \sum_{s=1}^{N} r_{s,v} = \ell_s \right\} \]

Proof. We note the following expansion which is valid for any bounded operators \( A_1, \ldots, A_N \) and sufficiently small \( \lambda, \)

\[ \log \left( (1 + P_n(e^{\lambda A_1} e^{\lambda A_2} \ldots e^{\lambda A_N} - I) P_n) \right) = \sum_{j=1}^{\infty} \frac{(-1)^{j+1}}{j} \operatorname{Tr} \left( P_n (e^{\lambda A_1} e^{\lambda A_2} \ldots e^{\lambda A_N} - I) P_n \right)^j \]

\[ = \sum_{j=1}^{\infty} \frac{(-1)^{j+1}}{j} \left( \sum_{\ell_1 + \ldots + \ell_N = \ell} \sum_{r_{1,1} + \ldots + r_{N,N} \geq 1} \lambda^{r_{1,1} + \ldots + r_{N,N}} \operatorname{Tr} P_n A_1^{r_{1,1}} \ldots A_N^{r_{N,N}} P_n \right)^j \]

\[ = \sum_{j=1}^{\infty} \frac{(-1)^{j+1}}{j} \sum_{\ell_1, \ldots, \ell_j = 1} \lambda^{\ell_1 + \ldots + \ell_j} \sum_{(r_{s,v})_{s=1}^{N} \in R_{\ell_1, \ldots, \ell_j}} \frac{\operatorname{Tr} \prod_{s=1}^{j} (P_n A_1^{r_{s,1}} \ldots A_N^{r_{s,N}} P_n)}{r_{1,1}! \ldots r_{1,N}! r_{2,1}! \ldots r_{2,N}! \ldots r_{j,1}! \ldots r_{j,N}!} \]

This proves the statement. \( \square \)

In the proofs of the main theorems it will be important to have the following continuity result.
Lemma 5.3. Let $A_1, \ldots, A_N$ and $B_1, \ldots, B_N$ be semi-infinite matrices, then

\[ |C_k^{(n)}(A_1, \ldots, A_N) - C_k^{(n)}(B_1, \ldots, B_N)| \leq \frac{2e}{(2 - \sqrt{e})^2} (2 \max(\sum_{j=1}^N \|A_j\|_\infty, \sum_{j=1}^N \|B_j\|_\infty))^{k-1} \sum_{j=1}^N \|A_j - B_j\|_1. \]

Proof. We start by writing

\[
\frac{1}{2\pi i} \oint_{|z| = \rho} \text{Tr} \left( \log \left( I + P_n \left( e^{\lambda A_1} e^{\lambda A_2} \cdots e^{\lambda A_N} - I \right) P_n \right) \\
- \log \left( I + P_n \left( e^{\lambda B_1} e^{\lambda B_2} \cdots e^{\lambda B_N} - I \right) P_n \right) \right) \frac{d\lambda}{\lambda^{k+1}}, \quad (5.6)
\]

We estimate the integrand using

\[
|\text{Tr} (\log(I + A) - \log(1 + B))| \leq \frac{\|A - B\|_1}{(1 - \|A\|_\infty)(1 - \|B\|_\infty)}. \quad (5.7)
\]

If we take $\rho = (2 \max(\sum_{j=1}^N \|A_j\|_\infty, \sum_{j=1}^N \|B_j\|_\infty))^{-1}$. Then

\[
\left\| e^{\lambda A_1} e^{\lambda A_2} \cdots e^{\lambda A_N} - I \right\|_\infty \leq \frac{\sqrt{e}}{2} \quad (5.8)
\]

\[
\left\| e^{\lambda B_1} e^{\lambda B_2} \cdots e^{\lambda B_N} - I \right\|_\infty \leq \frac{\sqrt{e}}{2} \quad (5.9)
\]

for $\lambda = \rho$. Moreover,

\[
\left\| e^{\lambda A_1} e^{\lambda A_2} \cdots e^{\lambda A_N} - I \right\|_1 = \left\| \sum_{j=1}^N e^{\lambda A_1} \cdots e^{\lambda A_{j-1}} \left( e^{\lambda A_j} - e^{\lambda B_j} \right) e^{\lambda B_{j+1}} \cdots e^{\lambda B_N} \right\|_1
\leq \sum_{j=1}^N \|e^{\lambda A_1}\|_\infty \cdots \|e^{\lambda A_{j-1}}\|_\infty \left\| e^{\lambda A_j} - e^{\lambda B_j} \right\|_1 \left\| e^{\lambda B_{j+1}} \cdots e^{\lambda B_N} \right\|_\infty
\leq |\lambda| \sum_{j=1}^N \|A_j - B_j\|_1 \exp |\lambda| \left( \sum_{j=1}^N (\|A_j\|_\infty + \|B_j\|_\infty) \right)
\leq \frac{e \sum_{j=1}^N \|A_j - B_j\|_1}{2 \max \left( \sum_{j=1}^N \|A_j\|_\infty, \sum_{j=1}^N \|B_j\|_\infty \right)} \quad (5.10)
\]

49
By substituting (5.8), (5.9) and (5.10) into (5.7) and using the result and the value of $\rho$ to estimate the integral (5.6) we obtain the statement. \hfill \qed

## 5.3 A comparison principle

In the next step we will prove a comparison principle for $C_k^n(A_1, \ldots, A_N)$ in case the $A_j$ are banded matrices.

We start with an easy lemma.

**Lemma 5.4.** Let $N \in \mathbb{N}$ and $A_1, \ldots, A_N$ banded matrices with $(A_j)_{rs} = 0$ if $|r - s| > a_j$. Then $A_1 \cdots A_N$ is a banded matrix such that $(A_1 \cdots A_N)_{rs} = 0$ if $|r - s| > a_1 + \cdots + a_N$ and $(A_1 \cdots A_N)_{rs}$ only depends on entries $(A_j)_{k\ell}$ with $|k - r|, |\ell - s| \leq a_1 + \cdots + a_N$ for $j = 1, \ldots, N$.

**Proof.** Write

$$(A_1 \cdots A_N)_{rs} = \sum_{v_1, \ldots, v_{N-1}} (A_1)_{rv_1}(A_2)_{v_1v_2} \cdots (A_N)_{v_{N-1}s}.$$  

By the assumption of the lemma, each term in the sum can only be non-zero if $|v_{j-1} - v_j| \leq a_j$ for $j = 1, \ldots, N$ (where we have set $v_0 = r$ and $v_N = s$ for notational convenience). But then by the triangular inequality, we see that the only possibility of obtaining a non-zero value is in case $|r - s| \leq a_1 + \cdots + a_N$, which proves the first part of the statement. Moreover, we only have contributions of entries $(A_j)_{v_{j-1}v_j}$ with

$$|r - v_{j-1}| \leq |r - v_1| + \cdots |v_{j-2} - v_{j-1}| \leq a_1 + \cdots + a_N,$$

and

$$|r - v_j| \leq |r - v_j| + \cdots |v_N - v_{N-1}| \leq a_1 + \cdots + a_N,$$

which proves the second part of the lemma. \hfill \qed

The following is the core of the proof of the main results of this paper.

**Proposition 5.5.** Let $N \in \mathbb{N}$ and $A_1, \ldots, A_N$ be banded matrices such that $(A_j)_{rs} = 0$ if $|r - s| > a_j$. Set $a = \sup_{j=1, \ldots, N} a_j$. Then

$$C_k^n(A_1, \ldots, A_N) = C_k^n(R_n,a(k+1)A_1R_n,a(k+1)), \ldots, R_n,2a(k+1)A_NR_n,2a(k+1))$$

where

$$R_n,\ell = P_{n+\ell} - P_{n-\ell}.$$
Proof. Note that we have
\[ \lambda \operatorname{Tr} (P_n A_1 P_n + \cdots + P_n A_N P_n) = \log \det \left( (I + (e^{\lambda P_n} A_1 P_n e^{\lambda P_n} A_2 P_n \cdots e^{\lambda P_n} A_N P_n - I) \right) \]

By expanding the right-hand side in the same way as in the proof of Lemma 5.2 and comparing terms at both sides, we find the identity
\[ \sum_{j=1}^{k} \frac{(-1)^j}{j} \sum_{\ell_1 + \cdots + \ell_j = k} \sum_{\ell_i \geq 1} \frac{\operatorname{Tr} \prod_{s=1}^{j} \left( P_n A_u P_n \right)^{r_{s,u}}}{r_{1,1}! \cdots r_{1,N}! r_{2,1}! \cdots r_{2,N}! \cdots r_{j,1}! \cdots r_{j,N}!} = 0, \]
for \( k \geq 2 \).

But then we can write
\[ C_k^{(n)} (A_1, \ldots, A_N) \]
\[ = \sum_{j=1}^{m} \frac{(-1)^{j+1}}{j} \sum_{\ell_1 + \cdots + \ell_j = k} \sum_{\ell_i \geq 1} \frac{\operatorname{Tr} \left( \prod_{s=1}^{j} \left( P_n A_1 A_2 \cdots A_N P_n \right)^{r_{1,1}! \cdots r_{1,N}! r_{2,1}! \cdots r_{2,N}! \cdots r_{j,1}! \cdots r_{j,N}!} \right)}{r_{1,1}! \cdots r_{1,N}! r_{2,1}! \cdots r_{2,N}! \cdots r_{j,1}! \cdots r_{j,N}!}, \]
for \( m \geq 2 \). We prove the theorem by showing that the each summand only depends on some entries of \( A_j \) that are all centered around the \( nn \)-entries.

Note that by a telescoping series, we have
\[ A_p^{r_{\ell,p}} - (P_n A_p P_n)^{r_{\ell,p}} = \sum_{q=0}^{r_{\ell,p}-1} A_p^{r_{\ell,p}-q}(P_n A_p P_n)(P_n A_p P_n)^q, \]
and
\[ P_n \left( \prod_{u=1}^{N} A_u^{r_{\ell,u}} \right) P_n - \prod_{u=1}^{N} (P_n A_u P_n)^{r_{\ell,u}} \]
\[ = \sum_{p=1}^{N} P_n \left( \prod_{u=1}^{p-1} A_u^{r_{\ell,u}} \right) \left( A_p^{r_{\ell,p}} - (P_n A_p P_n)^{r_{\ell,p}} \right) \left( \prod_{v=p+1}^{N} (P_n A_v P_n)^{r_{\ell,v}} \right) P_n \]
\[ = \sum_{p=1}^{N} \sum_{q=0}^{r_{\ell,p}-1} P_n \left( \prod_{u=1}^{p-1} A_u^{r_{\ell,u}} \right) A_p^{r_{\ell,p}-q}(P_n A_p P_n)(P_n A_p P_n)^q \]
\[ \times \left( \prod_{v=p+1}^{N} (P_n A_v P_n)^{r_{\ell,v}} \right) P_n. \]

51
We use the fact that $P_n^2$ to rewrite this to

$$
P_n \left( \prod_{u=1}^{N} A_{R,u}^{r_{x,u}} \right) P_n - \prod_{u=1}^{N} (P_n A_{u} P_n)^{r_{x,u}} \]

$$

$$
= \sum_{p=1}^{N} \sum_{q=0}^{r_{x,p}-1} P_n \left( \prod_{u=1}^{p-1} A_{R,u}^{r_{x,u}} \right) A_{P}^{r_{x,p}-q-1} (A_{p} P_n - A_{p} A_{p} P_n) (P_n A_{p} P_n)^{q} \]

$$

$$
\times \left( \prod_{v=p+1}^{N} (P_n A_{v} P_n)^{r_{x,v}} \right). \]

$$

Finally, by another telescoping series we find

$$
\prod_{s=1}^{j} \left( P_n A_{1}^{r_{x,1}} \cdots A_{N}^{r_{x,N}} P_n \right) \]

$$

$$
- \prod_{s=1}^{j} \left( P_n (A_{1} P_n)^{r_{x,1}} \cdots (A_{N} P_n)^{r_{x,N}} \right) \]

$$

$$
= \sum_{\ell=1}^{j} \sum_{p=1}^{N} \sum_{q=0}^{r_{x,p}-1} P_n \left( \prod_{s=1}^{\ell-1} \left( P_n A_{1}^{r_{x,1}} \cdots A_{N}^{r_{x,N}} P_n \right) P_n \left( \prod_{u=1}^{p-1} A_{R,u}^{r_{x,u}} \right) \right) \]

$$

$$
\times \left( A_{P}^{r_{x,p}-q-1} (A_{p} P_n - A_{p} A_{p} P_n) (P_n A_{p} P_n)^{q} \right) \]

$$

$$
\left( \prod_{v=p+1}^{N} (P_n A_{v} P_n)^{r_{x,v}} \right) \left( \prod_{s=\ell+1}^{j} \left( P_n (A_{1} P_n)^{r_{x,1}} \cdots (P_n A_{N} P_n)^{r_{x,N}} \right) \right) \]

$$

$$
= \sum_{\ell=1}^{j} \sum_{p=1}^{N} \sum_{q=0}^{r_{x,p}-1} \text{Tr} Q_1 (A_{p} P_n - A_{p} A_{p} P_n) Q_2 \]

$$

with

$$
Q_1 = \left( \prod_{s=1}^{\ell-1} \left( P_n A_{1}^{r_{x,1}} \cdots A_{N}^{r_{x,N}} P_n \right) P_n \left( \prod_{u=1}^{p-1} A_{R,u}^{r_{x,u}} \right) \right) A_{P}^{r_{x,p}-q-1} \]

$$

$$
Q_2 = (P_n A_{p} P_n)^{q} \left( \prod_{v=p+1}^{N} (P_n A_{v} P_n)^{r_{x,v}} \right) \left( \prod_{s=\ell+1}^{j} \left( P_n (A_{1} P_n)^{r_{x,1}} \cdots (P_n A_{N} P_n)^{r_{x,N}} \right) \right) \]

$$

Let us compute

$$
\text{Tr} Q_1 (A_{p} P_n - A_{p} A_{p} P_n) Q_2 = \sum_{r_0=1}^{n} \sum_{r_1,r_2=1}^{r_2} \left( Q_1 \right)_{r_0 r_1} (A_{p} P_n - A_{p} A_{p} P_n)_{r_1 r_2} (Q_2)_{r_2 r_0}. \]

$$

(5.11)
The fact of the matter is that because of the band structure the matrix
\[ A_p P_n - P_n A_p P_n \]
is of finite rank and the non-zero entries are concentrated around the \(nn\)-entry. Hence we can restrict the sum to terms with \(|r_{1,2} - n| \leq a\). Now, since \(Q_1\) and \(Q_2\) are a product of band matrices, they are themselves also band matrices. The number of terms in the product is at most \(k\) (ignoring the \(P_n\)) and the bandwidth of each term is at most \(a\). Hence \((Q_1)_{r_0 r_1} = 0\) if \(|r_0 - r_1| > ak\) and \((Q_2)_{r_2 r_0} = 0\) if \(|r_2 - r_0| > ak\). By combining the latter observations, we see that the trace in (5.11) only depends on \((Q_1)_{r_0 r_1}\) and \((Q_2)_{r_2 r_0}\) with \(|r_0 - n| \leq a(k + 1)\) and \(|r_{1,2} - n| \leq a\). By Lemma 5.4 we then also see that these entries only depend on entries \((A_m)_{rs}\) with \(|r - n| \leq a(k + 1)\) and \(|s - n| \leq a(k + 1)\) for \(m = 1, \ldots, N\). Concluding, we have that \(C_k^{(n)}(A_1, \ldots, A_N)\) only depends on \((A_m)_{rs} \) with \(|r - n| \leq 2a(k + 1)\) and \(|s - n| \leq 2a(k + 1)\), for \(m = 1, \ldots, N\). This proves the statement \(\square\)

**Corollary 5.6.** Let \(N \in \mathbb{N}\) and \(A_1, \ldots, A_N, B_1, \ldots B_N\) be banded matrices such that \((A_j)_{rs} = 0\) if \(|r - s| > a_j\) and \((B_j)_{rs} = 0\) if \(|r - s| > b_j\). Set \(c = \max\{a_j, b_j \mid j = 1, \ldots, N\}\). If

\[
\left| C_k^{(n)}(A_1, \ldots, A_N) - C_k^{(n)}(B_1, \ldots, B_N) \right| \\
\leq \left( \max \sum_{j=1}^{N} \| R_{n, 2c(k+1)} A_j R_{n, 2c(k+1)} \|_\infty, \sum_{j=1}^{N} \| R_{n, 2c(k+1)} B_j R_{n, 2c(k+1)} \|_\infty \right)^{k-1} \\
\times \frac{2k^2 c(k+1) e}{(2 - \sqrt{e})^2} \sum_{j=1}^{N} \| R_{n, 2c(k+1)} (A_j - B_j) R_{n, 2c(k+1)} \|_\infty, \quad (5.12)
\]

where \(R_{n, 2c(k+1)}\) is as in Proposition 5.3.

**Proof.** By combining Lemma 5.3 and Proposition 5.5 we obtain

\[
\left| C_k^{(n)}(A_1, \ldots, A_N) - C_k^{(n)}(B_1, \ldots, B_N) \right| \\
\leq (2 \max \sum_{j=1}^{N} \| R_{n, 2c(k+1)} A_j R_{n, 2c(k+1)} \|_\infty, \sum_{j=1}^{N} \| R_{n, 2c(k+1)} B_j R_{n, 2c(k+1)} \|_\infty \right)^{k-1} \\
\times \frac{2e}{(2 - \sqrt{e})^2} \sum_{j=1}^{N} \| R_{n, 2c(k+1)} A_j R_{n, 2c(k+1)} - R_{n, 2c(k+1)} B_j R_{n, 2c(k+1)} \|_1.
\]
Now the statement follows by noting that the ranks of
\[ R_{n,2c(k+1)}A_j R_{n,2c(k+1)} \text{ and } R_{n,2c(k+1)}B_j R_{n,2c(k+1)} \]
are \(4c(k + 1) + 1\) and for any finite rank operator \( R \) with rank \( r(R) \) we have
\[ \| R \|_1 \leq r(R) \| R \|_\infty. \]
\[ \square \]

Note that the latter corollary is a pure universality result. Whatever the limits are, they must be the same. It particularly implies that we only need to compute a special case to conclude a general result. This is what we will do in the next paragraph.

### 5.4 Special case of banded Toeplitz operators

We now compute the limiting values of \( C_m^{(n)}(A_1, \ldots, A_N) \) in case the \( A_j \) are banded Toeplitz operators. We will first recall various basic notions and properties we will need. For further details and background on Toeplitz operators we refer to the book [12].

For a Laurent polynomial \( a(z) = \sum_{j=-q}^{p} a_j z^j \), the Toeplitz operator \( T(a) \) is defined by the semi-infinite matrix
\[
(T(a))_{jk} = a_{j-k}, \quad j, k = 1, \ldots,
\]
viewed as an operator on \( \ell_2(\mathbb{N}) \). Of importance to us will also be the Hankel operator defined by the semi-infinite matrix
\[
(H(a))_{jk} = a_{j+k-1}, \quad j, k = 1, \ldots.
\]

Note that \( H(a) \) is of finite rank. The Toeplitz and Hankel operators are related by
\[
T(ab) = T(a)T(b) + H(a)H(\tilde{b}),
\]
with \( \tilde{b}(z) = b(1/z) \). An important consequence of this formula that we will frequently use is
\[
[T(a), T(b)] = H(b)H(\tilde{a}) - H(a)H(\tilde{b}). \quad (5.13)
\]

Finally, we mention that
\[
\| T(a) \|_\infty \leq \| a \|_{1,\infty}, \quad \text{and} \quad \| H(a) \|_\infty \leq \| a \|_{1,\infty}.
\]
5.4.1 The case $N$ fixed

The main purpose of this paragraph is to prove the following proposition.

**Proposition 5.7.** Let $N \in \mathbb{N}$ and $a(m, z) = \sum \ell a_{\ell}(m)z^{\ell}$ for $m = 1, \ldots, N$, be Laurent polynomials in $z$. For $m = 1, \ldots, N$ we denote the Toeplitz operator with symbol $a(m, z)$ by $T(a(m))$. Then

$$
\lim_{n \to \infty} \det \left( I + P_{n} \left( e^{T(a(1))} e^{T(a(2))} \cdots e^{T(a(N))} - I \right) P_{n} \right) e^{-n \sum_{m=1}^{N} a_{0}(m)}
= \exp \left( \sum_{m_{1}=1}^{N} \sum_{m_{2}=m_{1}+1}^{N} \sum_{\ell=1}^{\infty} \ell a_{\ell}(m_{1})a_{-\ell}(m_{2}) + \frac{1}{2} \sum_{m=1}^{N} \sum_{\ell=1}^{\infty} \ell a_{\ell}(m)a_{-\ell}(m) \right).
$$

(5.14)

Before we come to the proof we first mention that the following immediate corollary.

**Corollary 5.8.** Under the same assumptions and notations as in Proposition 5.7 we have

$$
\lim_{n \to \infty} C_{k}^{(n)}(T(a(1), \ldots, T(a(N))) = 0,
$$

for $k \geq 3$, and

$$
\lim_{n \to \infty} C_{2}^{(n)}(T(a(1), \ldots, T(a(N)))
= \sum_{m_{1}=1}^{N} \sum_{m_{2}=m_{1}+1}^{N} \sum_{\ell=1}^{\infty} \ell a_{\ell}(m_{1})a_{-\ell}(m_{2}) + \frac{1}{2} \sum_{m=1}^{N} \sum_{\ell=1}^{\infty} \ell a_{\ell}(m)a_{-\ell}(m)
$$

for $k = 2$.

The proof of Proposition 5.7 that we will present here relies on the following beautiful identity due to Ehrhardt.

**Lemma 5.9.** [20, Cor. 2.3] Let $A_{1}, \ldots, A_{N}$ be bounded operators such that

1. $A_{1} + \cdots + A_{N} = 0$,

2. $[A_{i}, A_{j}]$ is trace class for $1 \leq i < j \leq N$.

Then $e^{A_{1}}e^{A_{2}}\cdots e^{A_{N}} - I$ is of trace class and

$$
\det e^{A_{1}}e^{A_{2}}\cdots e^{A_{N}} = \exp \frac{1}{2} \sum_{1 \leq i < j \leq n} \text{Tr}[A_{i}, A_{j}],
$$

where the left-hand side is a Fredholm determinant.
Remark 5.1. In the special case $n = 3$ the identity reads

$$\det e^{-A}e^{A+B}e^{-B} = \exp \left( -\frac{1}{2} \text{Tr}[A,B] \right),$$

which is an identity that can be used that lies behind the Strong Szegő Limit Theorem. It has also been used in [10] in the context of Central Limit Theorem for linear statistics for biorthogonal ensembles.

We now come to the

**Proof of Proposition 5.7.** We start by defining $s(z) = \sum_{j=1}^{N} a(j, z)$ and split $s(z) = s_{+}(z) + s_{-}(z)$ where $s_{+}$ is the polynomial part of $s(z)$, i.e. $s_{+}(z) = \sum_{k \geq 0} s_{k}z^{k}$. Then we note that $T(s_{+})$ is lower triangular and $T(s_{-})$ is strictly upper triangular.

Hence

$$P_{n}T(s_{+})P_{n} = P_{n}T(s_{+}), \quad \text{and} \quad P_{n}T(s_{-})P_{n} = T(s_{-})P_{n}.$$  

By expanding the exponential and iterating the latter identities we therefore have (where we recall that $Q_{n} = I - P_{n}$)

$$e^{P_{n}T(s_{+})}P_{n} = P_{n}e^{T(s_{+})}P_{n} + Q_{n} = P_{n}e^{T(s_{+})} + Q_{n},$$

and

$$e^{P_{n}T(s_{-})}P_{n} = P_{n}e^{T(s_{-})}P_{n} + Q_{n} = e^{T(s_{-})}P_{n} + Q_{n}.$$  

Moreover,

$$\left( Q_{n} + P_{n}e^{T(s_{+})}P_{n} \right) \left( Q_{n} + P_{n}BP_{n} \right) \left( Q_{n} + P_{n}e^{T(s_{-})}P_{n} \right) = Q_{n} + P_{n}e^{T(s_{+})}P_{n}BP_{n}e^{T(s_{-})}P_{n} = Q_{n} + P_{n}e^{T(s_{+})}Be^{T(s_{-})}P_{n} = I + P_{n} \left( e^{T(s_{+})}Be^{T(s_{-})} - I \right) P_{n},$$  

(5.15)

for any operator $B$. We then write

$$e^{-n \sum_{j=1}^{N} a_{0}^{(j)}} = e^{-\text{Tr} P_{n}T(s_{+})P_{n}} = \det e^{-P_{n}T(s_{+})P_{n}} = \det \left( Q_{n} + P_{n}e^{-T(s_{+})}P_{n} \right),$$

and

$$1 = e^{-\text{Tr} P_{n}T(s_{+})P_{n}} = \det e^{-P_{n}T(s_{-})P_{n}} = \det \left( Q_{n} + P_{n}e^{-T(s_{-})}P_{n} \right).$$

By combining this with (5.15) and taking $B = e^{-T(s_{+})}e^{T(a(1))}e^{T(a(2))} \ldots e^{T(a(N))}$, we see that we can rewrite the left-hand side of (5.14) as

$$\det \left( I + P_{n} \left( e^{-T(s_{+})}e^{T(a(1))}e^{T(a(2))} \ldots e^{T(a(N))}e^{-T(s_{-})} - I \right) P_{n} \right).$$  

(5.16)
The idea is now to invoke Lemma 5.9. To this end, we first note that
\[ T(s) + \sum_{j=1}^{N} T(a^{(j)}) = 0, \]
and that for \(1 \leq j, k \leq N\) we have that
\[ [T(a_+(j)), T(a_-(k))] = H(a_+(j))H(a_-(k)), \]
is of finite rank and hence of trace class, from which it follows that also the second condition of the proposition is satisfied and that
\[ e^{-T(s_+)} e^{T(a^{(1)})} e^{T(a^{(2)})} \ldots e^{T(a^{(N)})} e^{-T(s_-)} - I \]
is of trace class. Hence,
\[ P_n \left( e^{-T(s_+)} e^{T(a^{(1)})} e^{T(a^{(2)})} \ldots e^{T(a^{(N)})} e^{-T(s_-)} - I \right) P_n \]
\[ = e^{-T(s_+)} e^{T(a^{(1)})} e^{T(a^{(2)})} \ldots e^{T(a^{(N)})} e^{-T(s_-)} - I, \quad (5.17) \]
in trace norm. By continuity of the Fredholm determinant we can therefore take the limit \(n \to \infty\) and obtain
\[ \lim_{n \to \infty} \det \left( I + P_n \left( e^{-T(s_+)} e^{T(a^{(1)})} e^{T(a^{(2)})} \ldots e^{T(a^{(N)})} e^{-T(s_-)} - I \right) P_n \right) \]
\[ = \det e^{T(s_+)} e^{T(a^{(1)})} e^{T(a^{(2)})} \ldots e^{T(a^{(N)})} e^{-T(s_-)}. \quad (5.18) \]
Moreover, by the same proposition,
\[ \det e^{-T(s_+)} e^{T(a^{(1)})} e^{T(a^{(2)})} \ldots e^{T(a^{(N)})} e^{-T(s_-)} = \exp \frac{1}{2} \text{Tr} S_1, \quad (5.19) \]
with
\[ S_1 = - \sum_{j=1}^{N} [T(s_+), T(a^{(j)})] + [T(s_-), T(s_-)] + \sum_{j=1}^{N} \sum_{k>j} [T(a(j)), T(a(k))] - \sum_{j=1}^{N} [T(a(j)), T(s_-)]. \]
By splitting \(a(m) = a_+(m) + a_-(m)\) and using the definition of \(s_\pm\), we can rewrite this to
\[ S_1 = \sum_{j=1}^{N} \sum_{k>j} [T(a(j)), T(a(k))] - \sum_{j=1}^{N} \sum_{k=1}^{N} [T(a(j)), T(a_-(k))]. \]
\[
N \sum_{j=1}^{N} \sum_{k>j} [T(a(j)), T(a_+(k))] - \sum_{j=1}^{N} \sum_{k\leq j} [T(a(j)), T(a_-(k))]
\]
\[
= \sum_{j=1}^{N} \sum_{k>j} H(a(k))H(\tilde{a}(j)) + \sum_{j=1}^{N} \sum_{k\leq j} H(a(j))H(\tilde{a}(k)),
\]
where in the last step we used (5.13). By taking the trace we find
\[
\text{Tr } S_1 = \sum_{j=1}^{N} \sum_{k=j+1}^{\infty} \ell a_\ell(k) a_{-\ell}(j) + \sum_{j=1}^{N} \sum_{k=1}^{\infty} \ell a_\ell(j) a_{-\ell}(k)
\]
\[
= 2 \sum_{j=1}^{N} \sum_{k=j+1}^{\infty} \ell a_\ell(k) a_{-\ell}(j) + \sum_{j=1}^{N} \sum_{\ell=1}^{\infty} \ell a_\ell(j) a_{-\ell}(j)
\]
Hence the statement follows after inserting the latter expression for Tr \(S_1\) into (5.19) and combining the result with (5.18)

5.4.2 The case \(N_n \to \infty\)

We now come to the case that \(N = N_n\) is depending on \(n\) in such a way that \(N_n \to \infty\) as \(n \to \infty\). In this paragraph we prove the following proposition.

**Proposition 5.10.** Let \(a(t, z) = \sum_{j=-q}^{p} a_j(t) z^j\) be a \(t\) dependent Laurent polynomial for which the \(a_j(t)\) are piecewise continuous on an interval \([\alpha, \beta]\).

Let \(\{N_n\}_{n\in\mathbb{N}}\) be a sequence such that \(N_n \to \infty\) as \(n \to \infty\). Moreover, for each \(n\) let
\[
\alpha = t_1^{(n)} < t_2^{(n)} < \ldots < t_N^{(n)} < t_{N_n+1}^{(n)} = \beta
\]
be a partitioning of \([\alpha, \beta]\) for which the mesh \(\sup_{j=0,\ldots,N_n} (t_{j+1} - t_j) \to 0\) as \(n \to \infty\). Then

\[
\det \left( I + P_n \left( \prod_{m=1}^{N_n} e^{(t_{m+1} - t_m)T(a(t_m^{(n)}))} - I \right) P_n \right) e^{-\sum_{m=1}^{N_n} (t_{m+1} - t_m)a_0(t_m^{(n)})}
\]
\[
= \exp \left( \sum_{\ell=1}^{\infty} \int_{0}^{\beta} \int_{0}^{\beta} \ell a_\ell(t_1) a_{-\ell}(t_2) dt_1 dt_2 \right)
\]

**Corollary 5.11.** Under the same assumptions and notations as in Proposition 5.10 we have
\[
\lim_{n \to \infty} C_k^{(n)}(T(a(1), \ldots, T(a(N_n))) = 0,
\]

58
for $k \geq 3$, and

$$\lim_{n \to \infty} C_k^{(n)}(T(a(1), \ldots, T(a(N))) = 2\sum_{\ell=1}^{\infty} \int_{0 < t_1 < t_2 < \beta} \ell a_\ell(t_1) a_{-\ell}(t_2) dt_1 dt_2,$$

for $k = 2$.

The proof of Proposition 5.10 goes along the same lines as the proof of Proposition 5.7. The main difficulty is that (5.17) (with $N$ and the symbols depending on $n$) is no longer immediate and requires a proof. Hence we can not deduce (5.18). We overcome this issue by proving the following.

**Lemma 5.12.** Let $\{N_n\}_n$ be a sequence of integers. For each $n \in \mathbb{N}$ let $A_j^{(n)}$ for $j = 1, \ldots, N_n$ be a family of Toeplitz operators satisfying the following conditions

- $A_1^{(n)} + \cdots + A_{N_n}^{(n)} = 0$
- the $A_j^{(n)}$’s are banded with width $c$ which is independent of $j$ and $n$.
- $\sum_{j=1}^{N_n} \|A_j^{(n)}\|_\infty < r$, for some constant $r$ independent of $n$.

Then

$$\lim_{n \to \infty} \left\| P_n \left( e^{A_1^{(n)}} \cdots e^{A_{N_n}^{(n)}} - I \right) P_n - \left( e^{A_1^{(n)}} \cdots e^{A_{N_n}^{(n)}} - I \right) \right\|_1 = 0. \quad (5.20)$$

**Proof.** Note that

$$P_n \left( e^{A_1^{(n)}} \cdots e^{A_{N_n}^{(n)}} - I \right) P_n - \left( e^{A_1^{(n)}} \cdots e^{A_{N_n}^{(n)}} - I \right) = -Q_n \left( e^{A_1^{(n)}} \cdots e^{A_{N_n}^{(n)}} - I \right) P_n - \left( e^{A_1^{(n)}} \cdots e^{A_{N_n}^{(n)}} - I \right) Q_n$$

Hence it suffices to prove that the two terms at the right-hand side separately converge to zero in trace norm. Here we will only show that for the second term, i.e. we show that

$$\lim_{n \to \infty} \left\| \left( e^{A_1^{(n)}} \cdots e^{A_{N_n}^{(n)}} - I \right) Q_n \right\|_1 \to 0. \quad (5.21)$$

The arguments for first term are analogous and left to the reader.
We first claim that for \( A_j \) and \( r, c \) satisfying the stated conditions, we have
\[
\left\| (e^{A_1} \cdots e^{A_N} - I) Q_n \right\|_1 \leq e^{2r} \sum_{2 \leq s < t \leq N} \| [A_s, A_t] \|_1 \sum_{m_2 + m_3 \geq n/(2c)} \frac{r^{m_2+m_3}}{m_2!m_3!},
\]
for any \( n \geq 2c \) and \( N \in \mathbb{N} \).

The proof of this statement goes by induction to \( N \).

We start with \( N = 3 \). In that case we recall a result from [11, Lem. 4.2] that if \( A_1 + A_2 + A_3 = 0 \) then
\[
e^{A_1} e^{A_2} e^{A_3} - I = \sum_{m_1=0}^{\infty} \sum_{m_2=1}^{\infty} \sum_{m_3=0}^{\infty} \sum_{j=0}^{m_2-j-1} \frac{A_1^{m_1} A_2^{j} [A_2, A_3] A_2^{m_2-j-1} A_3^{m_3}}{m_1! m_2! m_3! (m_1 + m_2 + m_3 + 1)},
\]
(this follows easily after differentiating \( e^{A_1} e^{A_2} e^{A_3} \) with respect to \( t \), expanding the exponentials and then integrate again for \( t \) from 0 to 1). Since \( A_j \) are banded with bandwidth \( c \) we also have \( A_2^{m_2-j-1} A_3^{m_3} \) is banded with bandwidth \( c(m_2 + m_3 - j - 1) \) but that means that
\[
A_2^{m_2-j-1} A_3^{m_3} Q_n = Q_{n-c(m_2+m_3-j-1)} A_2^{m_2-j-1} A_3^{m_3} Q_n
\]
and thus
\[
[A_2, A_3] A_2^{m_2-j-1} A_3^{m_3} Q_n = [A_2, A_3] Q_{n-c(m_2+m_3-j-1)} A_2^{m_2-j-1} A_3^{m_3} Q_n.
\]

Since by assumption \( A_2 \) and \( B_3 \) are banded Toeplitz matrices of bandwith \( c \), we see by [5,13] that \( [A_1, A_2] \) is sum of product of two Hankel matrices with Laurent polynomials as their symbols. All the non-trivial entries for these Hankel operators are in the upper left \( c \times c \) block and hence
\[
[A_2, A_3] Q_m = 0
\]
f for \( m \geq c \). Hence, for \( n \geq 2c \), we can restrict the sum to terms with \( m_2 + m_3 \geq n/2c \) and write
\[
\left\| (e^{-A} e^{A} e^{-B} - I) Q_n \right\|_1
\]
\[
= \left\| \sum_{m_1=0}^{\infty} \sum_{m_2 \geq 1, m_3 \geq 0} \sum_{m_2 + m_3 \geq n/2c} \sum_{j=0}^{m_2-j-1} \frac{(A_1)^{m_1} (A_2)^{j} [A_2, A_3] (A_2)^{m_2-j-1} (A_3)^{m_3} Q_n}{m_1! m_2! m_3! (m_1 + m_2 + m_3 + 1)} \right\|_1
\]
60
\[ \leq \sum_{m_3=0}^{\infty} \sum_{m_2 \geq 1, m_3 \geq 0, m_2 + m_3 \geq n/2c} \sum_{j=0}^{m_2-1} \frac{\|A_1\|_\infty \|A_2\|_\infty^2 \|A_1, A_2\|_1 \|A_2\|_\infty^{m_2-j-1} \|A_3\|_\infty^3}{m_1! m_2! m_3! (m_1 + m_2 + m_3 + 1)} \leq e^{r} \|A_2, A_3\|_1 \sum_{m_2 + m_3 \geq n/(2c)} \frac{r^{m_2+m_3}}{m_2! m_3!}, \]

and this proves the statement for \( N = 3 \) (with a slightly better bound).

Now suppose the statement is true for for \( N - 1 \geq 2 \). We then first write
\[ e^{A_1} e^{A_2} \ldots e^{A_N} - I = e^{A_1} e^{A_2} \ldots e^{A_{N-2}} e^{A_{N-1} + A_N} (e^{-A_{N-1} - A_N} e^{A_{N-1}} e^{A_N} - I) \]
\[ + e^{A_1} e^{A_2} \ldots e^{A_{N-2}} e^{A_{N-1} + A_N} - I. \]

The first term at the right-hand side can be estimate by as in the case \( N = 3 \) giving
\[ \|e^{A_1} e^{A_2} \ldots e^{A_{N-2}} e^{A_{N-1} + A_N} (e^{-A_{N-1} - A_N} e^{A_{N-1}} e^{A_N} - I)\|_1 \leq e^{\sum_{j=1}^{N} \|A_j\|_\infty} \|e^{-A_{N-1} - A_N} e^{A_{N-1}} e^{A_N} - I\|_1 \leq e^{2r} \|[A_{N-1}, A_N]\|_1 \sum_{m_2 + m_3 \geq n/(2c)} \frac{r^{m_2+m_3}}{m_2! m_3!}. \quad (5.23) \]

Moreover, since
\[ \sum_{j=1}^{N} \|A_j\|_\infty + \|A_{N-1} + A_N\|_\infty < \sum_{j=1}^{N} \|A_j\|_\infty \leq r \]
and \( A_{N-1} + A_N \) by linearity is also a Toeplitz operator with bandwidth \( c \), we have by the induction hypothesis that we find that
\[ \|e^{A_1} e^{A_2} \ldots e^{A_{N-2}} e^{A_{N-1} + A_N} - I\| \leq e^{2r} \left( \sum_{1 \leq s < t \leq N-2} \|[A_s, A_t]\|_1 + \sum_{s=1}^{N-2} \|[A_s, A_{N-1} + A_N]\|_1 \right) \sum_{m_2 + m_3 \geq n/(2c)} \frac{r^{m_2+m_3}}{m_2! m_3!} \]
\[ \leq e^{2r} \left( \sum_{1 \leq s < t \leq N-1} \|[A_s, A_t]\|_1 + \sum_{s=1}^{N-1} \|[A_s, A_N]\|_1 \right) \sum_{m_2 + m_3 \geq n/(2c)} \frac{r^{m_2+m_3}}{m_2! m_3!}. \quad (5.24) \]

Hence, by combining the (5.23) and (5.24) we obtain the claim (5.22) for any \( N \in \mathbb{N} \).
To finish the proof we recall again that by (5.13) we have that \([A_s, A_t]\) is sum of product of two Hankel matrices with Laurent polynomials as their symbols. All the non-trivial entries for these Hankel operators are in the upper left \(c \times c\) block and hence they are of rank \(c\). Since we also have \(\|H(a)\|_{\infty} \leq \|T(a)\|_{\infty}\), we therefore find

\[
\| [A_s, A_t] \|_1 \leq 2c^2 \| A_s \|_{\infty} \| A_t \|_{\infty}.
\]

But then we have

\[
\sum_{2 \leq s < t \leq N} \| [A_s, A_t] \|_1 \leq 2c^2 \sum_{2 \leq s < t \leq N} \| A_s \|_{\infty} \| A_t \|_{\infty} < r^2 e^2.
\]

After inserting this into (5.22) we obtain

\[
\left\| (e^{A_1} \cdots e^{A_N} - I) Q_n \right\|_1 \leq 2r^2 c^2 e^{2r} \sum_{m_2 + m_3 \geq n/(2c)} \frac{r^{m_2 + m_3}}{m_2! m_3}!
\]

for any \(n \geq 2c\), \(N \in \mathbb{N}\) and operators \(\{A_j\}_{j=1}^N\) satisfying the conditions of the proposition (with respect to \(c\) and \(r\)). By setting \(N = N_n, A_j = A_j^{(n)}\) and taking \(n \to \infty\) we obtain (5.21). This finishes the proof. \(\square\)

**Proof.** Proof of Proposition 5.10 We argue exactly the same as in the proof of 5.7 until (5.16) giving

\[
\det \left( I + P_n \begin{pmatrix} e^{A_1^{(n)}} & \cdots & e^{A_{N+1}^{(n)}} - I \end{pmatrix} P_n \right).
\]

where

\[
A_m^{(n)} = (t_m^{(n)} - t_m^{(n)}) T(a(t_m^{(n)})), \quad m = 1, \ldots, N
\]

and

\[
A_0^{(n)} = - \sum_{m=1}^N (t_m^{(n)} - t_m^{(n)}) T(a+(t_m^{(n)})), \quad A_{N+1}^{(n)} = - \sum_{m=1}^N (t_m^{(n)} - t_m^{(n)}) T(a-(t_m^{(n)})).
\]

Hence it is clear that \(A_0^{(n)} + \ldots + A_{N+1}^{(n)} = 0\). Moreover, each \(A_m^{(n)}\) is a banded Toeplitz matrix with band-width \(\max(p, q)\). Finally, we check the condition on the norm of the matrices. To this end,

\[
\sum_{m=1}^N \| A_m^{(n)} \|_{\infty} = \sum_{m=1}^N (t_{m+1}^{(n)} - t_m^{(n)}) \| T(a(t_m^{(n)})) \|_{\infty}
\]

62
\[ \sum_{m=1}^{N} (t_{m+1}^{(n)} - t_{m}^{(n)}) ||a(t_{m}^{(n)})||_{\infty} \leq (\beta - \alpha) \sup_{t} ||a(t)||_{\infty} \leq (\beta - \alpha) \sum_{j=-q}^{p} \sup_{t} |a_{j}(t)|. \] (5.26)

The latter is finite, since we assume that the \( a_{j} \) are piecewise continuous. A similar argument shows that also
\[ \|A_{0}^{(n)}\|_{\infty}, \|A_{N+1}^{(n)}\| \leq \sum_{j=-q}^{p} \sup_{t} |a_{j}(t)|. \]
Hence the last condition of Lemma 5.12 is also satisfied. It then follows from that lemma, that
\[ \lim_{n \to \infty} \det \left( I + P_{n} \left( e^{A_{0}^{(n)}} e^{A_{1}^{(n)}} \cdots e^{A_{N+1}^{(n)}} - I \right) P_{n} \right) = \lim_{n \to \infty} \det \left( e^{A_{0}^{(n)}} e^{A_{1}^{(n)}} \cdots e^{A_{N+1}^{(n)}} \right). \] (5.27)

The right-hand side is the exponential of a trace that we can compute in the same way as we have done in the proof of Proposition 5.7 which gives
\[ \lim_{n \to \infty} \det \left( I + P_{n} \left( e^{A_{0}^{(n)}} e^{A_{1}^{(n)}} \cdots e^{A_{N+1}^{(n)}} - I \right) P_{n} \right) = \lim_{n \to \infty} \exp \left( 2 \sum_{m=1}^{N} (t_{m+1}^{(n)} - t_{m}^{(n)}) \sum_{m_{2}=m_{1}+1}^{N} (t_{m_{2}+1}^{(n)} - t_{m_{2}}^{(n)}) \sum_{\ell=1}^{\infty} \ell a_{\ell}(t_{m_{1}}^{(n)}) a_{-\ell}(t_{m_{m_{2}}}) \right. \]
\[ + \left. \sum_{m=1}^{N} (t_{m+1}^{(n)} - t_{m}^{(n)})^{2} \sum_{\ell=1}^{\infty} \ell a_{\ell}(m) a_{-\ell}(m) \right). \] (5.28)

In the limit \( n \to \infty \), the double sum in the exponent converges to a Riemann-Stieltjes integral and the single sum tends to zero. We thus proved the statement.

6 Proofs of the main results

6.1 Proof of Theorem 2.2

Proof of Theorem 2.2. To prove that the difference of the moments converges to zero, it is sufficient to prove that for \( k \geq 2 \) we have
\[ C_{k}(X_{n}(f)) - \tilde{C}_{k}(X_{n}(f)) \to 0, \]
as \( n \to \infty \), where the \( C_{k}'s \) are the cumulants defined in (4.7). By Lemmas 4.1 and 4.2 and this means that we need to prove that, for given \( k \geq 2, \)
\[ C_{k}^{(n)}(f(1, \bar{J}_{1,S}), \ldots, f(N, \bar{J}_{N,S})) - C_{k}^{(n)}(f(1, \bar{J}_{1,S}), \ldots, f(N, \bar{J}_{N,S})) \to 0, \] (6.1)
as \( n \to \infty \) for \( S \) sufficiently large. The key ingredient is Corollary 5.6.

Since \( x \mapsto f(m, x) \) is a polynomial and \( \tilde{J}_m \) and \( \tilde{J}_m \) are banded, it is not hard to see that (2.13) implies that, for given \( k, \ell \in \mathbb{Z} \),

\[
(f(m, \tilde{J}_m))_{n+k,n+\ell} - (f(m, \tilde{J}_m))_{n+k,n+\ell} \to 0,
\]
as \( n \to \infty \).

Now, let \( k \in \mathbb{N} \). Note that for any \( S \in \mathbb{N} \) we have that both \( f(m, \tilde{J}_m,S) \) and \( f(m, \tilde{J}_m,S) \) are banded matrices with a bandwidth \( \rho \) that is independent of \( n \). With \( R_{n,2\rho(k+1)} \) as in Corollary 5.6 we then have

\[
\left\| R_{n,2\rho(k+1)} \left( f(m, \tilde{J}_m,S) - f(m, \tilde{J}_m,S) \right) R_{n,2\rho(k+1)} \right\|_{\infty} \to 0, \quad (6.2)
\]
as \( n \to \infty \) for sufficiently large \( S \). We also have by the first condition in Theorem 2.2 that there exists an \( M > 0 \) such that

\[
\left\| R_{n,2\rho(k+1)} f(m, \tilde{J}_m,S) R_{n,2\rho(k+1)} \right\|_{\infty} < M, \quad (6.3)
\]
for \( n \in \mathbb{N} \). Hence, by (6.2), we can also choose \( M \) to be large enough so that we have

\[
\left\| R_{n,2\rho(k+1)} f(m, \tilde{J}_m,S) R_{n,2\rho(k+1)} \right\|_{\infty} < M, \quad (6.4)
\]
for \( n \in \mathbb{N} \). The statement now follows by (6.1) and inserting (6.2), (6.3) and (6.4) for sufficiently large \( S \) into the conclusion of Corollary 5.6.

6.2 Proof of Theorem 2.3

Proof of Theorem 2.3. To prove that \( X_n(f) - \mathbb{E}X_n(f) \) converges to a normally distributed random variable, it is sufficient to prove that the \( k \)-th cumulant converges to zero if \( k \geq 3 \) and to the stated value of the variance if \( k = 2 \). By (5.3) this means that we need to show that, for given \( k > 2 \),

\[
\lim_{n \to \infty} C_k^{(n)} (f(1, \tilde{J}_1,S), \cdots, f(N, \tilde{J}_N,S)) = 0,
\]
for some sufficiently large \( S \), and that the variance \( C_k^{(n)} \) converges to the stated value.

Let \( k \in \mathbb{N} \). The assumptions of the theorem imply that

\[
\lim_{n \to \infty} \left( (\tilde{T}_m))_{n+k,n+l} - (T(a(m)))_{n+k,n+l} \right) = 0,
\]
for some sufficiently large \( S \).
with \( a(z) = \sum_{j=-q}^{p} a_j^{(m)} z^j \) where \( a_j \) are the values in (2.15). Since \( x \mapsto f(x,m) \) is a polynomial it is not hard to see that also
\[
\lim_{n \to \infty} \left( (f(m,J_{m,s}))_{n+k,n+l} - (T(b(m)))_{k,l} \right) = 0,
\]
for a sufficiently large \( S \) and with \( b(m) = \sum_k f_k^{(m)} z^k \) and \( f_k^{(m)} \) as in (2.17).

The statement then follows after applying Corollaries 5.6 and 5.8. \( \square \)

### 6.3 Proof of Theorem 2.5

We now show how the results can be extended to allow for more general functions in the case (2.10). We recall that the variance of the linear statistics is given in terms of the kernel \( K_{n,N} \) as in (4.1). Note that for fixed \( m \) the kernel in this situation reads
\[
K_{n,N}(m,x,m,y) = \sum_{j=1}^{n} p_j(m) p_j(y),
\]
and hence \( K_{n,N}(m,x,m,y) = K_{n,N}(m,y,m,x) \). This symmetry is a key property in the coming analysis. We start with the following estimate on the variance.

**Lemma 6.1.** Let \( f(m,x) \) be such that \( \frac{\partial f}{\partial x}(m,x) \) is a bounded function. Then
\[
\text{Var} \sum_{m=1}^{N} \sum_{j=1}^{n} f(m,x_j(t_m)) \leq N \sum_{m=1}^{N} \left\| \frac{\partial f}{\partial x}(m,x) \right\|_{\infty}^2 \left\| [P_n,J_m] \right\|_2^2.
\]

**Proof.** Let us first deal with the special case that \( N = 1 \). In that case, the variance of a linear statistic can be written as (with \( K_{n,N}(x,1,y,1) \) shortened to \( K_{n,N}(x,y) \))
\[
\text{Var} \sum_{j=1}^{n} f(x_j(t)) = \int f(x)^2 K_{n,N}(x,x) d\mu(x)
- \iint f(x)f(y) K_{n,N}(x,y) K_{n,N}(y,x) d\mu(x) d\mu(y)
\]
By using the fact that, by orthogonality, we have \( \int K_{n,N}(x,y) K_{n,N}(y,x) d\mu(y) = K_{n,N}(x,x) \) we can rewrite this in symmetric form
\[
\text{Var} \sum_{j=1}^{n} f(x_j(t)) = \frac{1}{2} \iint (f(x) - f(y))^2 K_{n,N}(x,y) K_{n,N}(y,x) d\mu(x) d\mu(y).
\]

(6.5)
We now use the fact that $K_{n,N}(x,y)$ is symmetric (and hence $K_{n,N}(x,y)K_{n,N}(y,x) \geq 0$) to estimate this as

$$\text{Var} \sum_{j=1}^{n} f(x_j(t)) \leq \frac{1}{2} \|f'\|_{\infty} \iint (x-y)^2 K_{n,N}(x,y)K_{n,N}(y,x) d\mu(x)d\mu(y).$$

(6.6)

It remains to estimate the double integral. To this end, we note that

$$\frac{1}{2} \iint (x-y)^2 K_{n,N}(x,y)K_{n,N}(y,x) d\mu(x)d\mu(y) = \|[P_n, J]\|_2^2,$$

proving the statement for $N = 1$. For general $N$ we use the inequality

$$\text{Var} \sum_{m=1}^{N} X_m \leq N \sum_{m=1}^{N} \text{Var} X_m,$$

valid for any sum of random variables. \qed

In the next lemma, we show that we can approximate the variance for linear statistics by linear statistic corresponding to polynomials.

**Lemma 6.2.** Assume there exists a compact set $E \subset \mathbb{R}$ such that

(1) $S(\mu^{(n)}_m) \subset E$ for $m = 1, \ldots, N$ and $n \in \mathbb{N}$,

or, more generally,

(2) for $k \in \mathbb{N}$ and $m = 1, \ldots, N$ we have

$$\int_{\mathbb{R}\setminus E} |x|^k K_{n,N}(m,x,m,x) d\mu^{(n)}_m(x) = o(1/n),$$

as $n \to \infty$.

Then for any function $f$ such that $x \mapsto f(m,x)$ is a continuously differentiable function with at most polynomial growth at $\pm \infty$, we have

$$\text{Var} X_n(f) \leq N \sum_{m=1}^{N} \sup_{x \in E} \left| \frac{\partial f}{\partial x}(m, x) \right|^2 \|[P_n, J_m]\|_2^2 + o(1),$$

(6.7)

as $n \to \infty$.

**Proof.** If the supports of $\mu^{(m)}$ all lie within a compact set of $\mathbb{R}$ (independent of $n$) then this is simply Lemma 6.1. Now suppose the measure is not compactly supported but condition (2) is satisfied with some $E$. Then we write again

$$\text{Var} \sum_{m=1}^{N} \sum_{j=1}^{n} f(m, x_j(t_m)) \leq N \sum_{m=1}^{N} \text{Var} \sum_{j=1}^{n} f(m, x_j(t_m)).$$

(6.8)
Each term in the sum at the right-hand side can be written in the form of (6.5) and we have

\[
\text{Var} \sum_{j=1}^{n} f(m, x_j(t_m)) = \frac{1}{2} \int \int_{E \times E} (f(m, x) - f(m, y))^2 K_{n,N}(m, x, y)K_{n,N}(m, y, x) d\mu(x) d\mu(y) + \frac{1}{2} \int \int_{(\mathbb{R} \setminus E) \times E} (f(m, x) - f(m, y))^2 K_{n,N}(m, x, y)K_{n,N}(m, y, x) d\mu(x) d\mu(y) + \frac{1}{2} \int \int_{\mathbb{R} \times (\mathbb{R} \setminus E)} (f(m, x) - f(m, y))^2 K_{n,N}(m, x, y)K_{n,N}(m, y, x) d\mu(x) d\mu(y). \tag{6.9}
\]

Now, since

\[K_{n,N}(m, x, m, y)K_{n,N}(m, y, m, x) \leq K_{n,N}(m, x, m, x)K_{n,N}(m, y, m, y),\]

and \(g\) has at most polynomial growth at infinity, we have

\[
\int_{\mathbb{R}} K_{n,N}(m, y, m, y) d\mu(y) = n,
\]

and \(g\) has at most polynomial growth at infinity, we have

\[
\int_{\mathbb{R}}(f(m, x) - f(m, y))^2 K_{n,N}(m, x, y)K_{n,N}(m, y, x) d\mu(x) d\mu(y) \leq \int_{(\mathbb{R} \setminus E) \times E}(f(m, x) - f(m, y))^2 K_{n,N}(m, x, y)K_{n,N}(m, y, x) d\mu(x) d\mu(y) = \mathcal{O}(1/n) \int K_{n,N}(m, y, m, y) d\mu(y) = \mathcal{O}(1), \tag{6.10}
\]

as \(n \to \infty\). For the same reasons,

\[
\int_{\mathbb{R} \times (\mathbb{R} \setminus E)}(f(m, x) - f(m, y))^2 K_{n,N}(m, m, y)K_{n,N}(m, y, m) d\mu(x) d\mu(y) = \mathcal{O}(1), \tag{6.11}
\]

as \(n \to \infty\). Moreover

\[
\int_{E \times E}(f(m, x) - f(m, y))^2 K_{n,N}(m, x, m, y)K_{n,N}(m, y, m, x) d\mu(x) d\mu(y) \leq \sup_{x \in E} \left| \frac{\partial f}{\partial x}(m, x) \right|^2 \int_{E \times E}(x - y)^2 K_{n,N}(m, x, m, y)K_{n,N}(m, y, m, x) d\mu(x) d\mu(y)
\]
\[
\leq \sup_{x \in E} \left| \frac{\partial f}{\partial x}(m, x) \right|^2 \int_{\mathbb{R} \times \mathbb{R}} (x-y)^2 K_{n,N}(m, x, m, y) K_{n,N}(m, y, m, x) d\mu(x) d\mu(y) \\
= \sup_{x \in E} \left| \frac{\partial f}{\partial x}(m, x) \right|^2 \left\| [P_n, J_m] \right\|^2_2. \quad (6.12)
\]

By inserting (6.10), (6.11) and (6.12) into (6.9) and the result into (6.8), we obtain the statement.

We need one more lemma.

**Lemma 6.3.** Let \( a_0^{(m)} \in \mathbb{R} \) and \( a_1^{(m)} > 0 \) for \( m = 1, \ldots, N \). Then for any real valued function \( f \) on \( \{1, \ldots, N\} \times \mathbb{R} \) such that \( x \mapsto f(m, x) \) is continuously differentiable, we have that

\[
\sigma(f)^2 = \sum_{k=1}^{\infty} \sum_{m_1, m_2 = 1}^{\infty} e^{-|\tau_{m_1} - \tau_{m_2}|k} f_k^{(m_1)} f_k^{(m_2)}
\]

is finite, where

\[
f_k^{(m)} = \frac{1}{2\pi} \int_0^{2\pi} f \left( m, a_0^{(m)} + 2a_1^{(m)} \cos \theta \right) e^{-ik\theta} d\theta.
\]

Moreover, for some constant \( C \) we have

\[
\sigma(f)^2 \leq C N \sum_{m=1}^{N} \sup_{x \in F_m} \left| \frac{\partial f}{\partial x}(m, x) \right|^2,
\]

where \( F_m = [a_0^{(m)} - 2a_1^{(m)}, a_0^{(m)} + 2a_1^{(m)}] \).

**Proof.** We start by recalling Remark 2.4 on the symmetric case. By the same arguments leading to (2.23), we see that we can write

\[
\sigma(f)^2 = \sum_{k=1}^{\infty} \int_{-\infty}^{\infty} \left| \sum_{m=1}^{N} e^{-i\tau_{m} \omega} k f_k^{(m)} \right|^2 \frac{d\omega}{k^2 + \omega^2},
\]

showing that \( \sigma(f)^2 \) is indeed positive (if finite). To show that it is finite, we note by applying Cauchy-Schwarz on the sum over \( m \) and using

\[
\int \frac{d\omega}{k^2 + \omega^2} \lesssim \int \frac{d\omega}{1 + \omega^2} = \pi,
\]

(6.13)
it easily follows that
\[ \sigma(f)^2 \leq C_0 N \sum_{m=1}^{N} \sum_{k=1}^{\infty} k^2 |f_k^{(m)}|^2. \]  
(6.14)

for some constant \( C_0 > 0 \). Then by integration by parts we find
\[ kf_k^{(m)} = \frac{1}{2\pi} \int_0^{2\pi} \frac{\partial f}{\partial x} (m, a_0^{(m)} + 2a_1^{(m)} \cos \theta) a_1^{(m)} \sin \theta \ e^{-ik\theta} \ d\theta. \]

By applying Parseval and using the compactness of \( F \) to estimate the \( L_2 \) norm by the \( L_\infty \) norm, we find there exists a constant \( C \) such that
\[ \sum_{k=1}^{\infty} k^2 |f_k^{(m)}|^2 \leq C \sup_{x \in F} \left| \frac{\partial f}{\partial x} (m, x) \right|^2. \]

By inserting this back into (6.14) we obtain the statement. \( \square \)

**Proof of Theorem 2.5.** For any function \( p \) on \( \{1, \ldots, N\} \times \mathbb{R} \) such that \( x \mapsto p(m, x) \) is a polynomial we can write
\[ \left| \mathbb{E} \left[ e^{itX_n(f)} \right] - e^{-\frac{\sigma(t)^2}{2}} \right| \leq \left| \mathbb{E} \left[ e^{itX_n(f)} \right] - \mathbb{E} \left[ e^{itX_n(p)} \right] \right| \\
+ \left| \mathbb{E} \left[ e^{itX_n(p)} \right] - e^{-\frac{\sigma(p)^2}{2}} \right| + \left| e^{-\frac{\sigma(p)^2}{2}} - e^{-\frac{\sigma(f)^2}{2}} \right| \]  
(6.15)

We claim that we can choose \( p \) such that the first and last term at the right-hand side are small. Let \( G \) be a compact set containing both the compact set \( E \) and all \( F_m \) from Lemma’s [6.2] and [6.3] respectively. For \( \varepsilon > 0 \), choose \( p \) such that
\[ \sum_{m=1}^{N} \sup_{x \in F_m} \left| \frac{\partial f}{\partial x} (m, x) - \frac{\partial p}{\partial x} (m, x) \right|^2 < \varepsilon, \]  
(6.16)

and such that \( p(m, x) \) is a polynomial in \( x \). Also note that by the assumptions of Theorem [2.3] there exists a constant \( C_0 \) such that
\[ \|[P_n, J_m]\|_2 \leq C_0, \]  
(6.17)

for \( n \in \mathbb{N} \) and \( m = 1, \ldots, N \).

We now recall that for any two real valued random variables \( X, Y \) with \( \mathbb{E}X = \mathbb{E}Y \) we have the identity
\[
|E[e^{itX}] - E[e^{itY}]| = |E[e^{itX} - e^{itY}]| \leq E\left|1 - e^{it(X-Y)}\right| \\
\leq |t|E||X-Y|| \leq |t|\sqrt{\text{Var}(X-Y)}, \quad (6.18)
\]
for \( t \in \mathbb{R} \). This means by Lemma 6.2, (6.16) and (6.17), that
\[
|E\left[e^{itX_n(f)}\right] - E\left[e^{itX_n(p)}\right]| \leq |t|\sqrt{\text{Var}(f-p)} \leq |t|C_1\varepsilon,
\]
for \( t \in \mathbb{R} \) some constant \( C_1 \). Moreover, by Lemma 6.3 and (6.16) we have that
\[
\left|e^{-\sigma^2 t^2} - e^{-\sigma^2 t^2/2}\right| \leq C_2\varepsilon
\]
for some constant \( C_2 \). By substituting this back into (6.15) and applying Theorem 2.3 we obtain
\[
\left|E\left[e^{itX_n(f)}\right] - e^{-\sigma^2 t^2/2}\right| \leq (C_1+C_2)\varepsilon \to (C_1+C_2)\varepsilon,
\]
as \( n \to \infty \). Since \( \varepsilon \) was arbitrary, we have \( \left|E\left[e^{itX_n(f)}\right] - e^{-\sigma^2 t^2/2}\right| \to 0 \) as \( n \to \infty \) and the statement follows.

6.4 Proof of Theorem 2.6

Proof of Theorem 2.6. The proof is a simple extension of the proof of Theorem 2.2 and is again a consequence of Corollary 5.6. The main difference being that (6.2), (6.3) and (6.4) are not sufficient, since the the number of terms in Corollary 5.6 grows with \( n \). Instead, we replace (6.2) with
\[
\sum_{m=1}^{N_n} \left\|R_{n,2\rho(k+1)}(f(m,\bar{J}_m,S) - f(m,\tilde{J}_m,S)\right\|_\infty \\
\leq \sum_{m=1}^{N_n} (t_m^{(n)} - t_m^{(n)})\left\|R_{n,2\rho(k+1)}\left(g(m,\bar{J}_m,S) - g(m,\tilde{J}_m,S)\right)\right\|_\infty \\
\leq (\beta-\alpha)\sup_{m=1,...,N_n} \left\|R_{n,2\rho(k+1)}\left(g(m,\bar{J}_m,S) - g(m,\tilde{J}_m,S)\right)\right\|_\infty \to 0,
\]
as \( n \to \infty \) for sufficiently large \( S \), by the condition (2.25) (and the exact same reasoning as in the beginning of the proof of Theorem 2.5). We also replace (6.3) by
\[ \sum_{m=1}^{N_n} \left\| R_{n,2\rho(k+1)}f(m,\tilde{J}_{m,S})R_{n,2\rho(k+1)} \right\|_\infty \]

\[ \leq \sum_{m=1}^{N_n} (t_{m+1}^{(n)} - t_m^{(n)}) \left\| R_{n,2\rho(k+1)}g(m,\tilde{J}_{m,S})R_{n,2\rho(k+1)} \right\|_\infty \]

\[ \leq (\beta - \alpha) \sup_{m=1,...,N_n} \left\| R_{n,2\rho(k+1)}g(m,\tilde{J}_{m,S})R_{n,2\rho(k+1)} \right\|_\infty, \quad (6.19) \]

which is bounded in \( n \) by the assumption in the theorem and the fact that \( g(m,x) \) is a polynomial in \( x \). This also shows that

\[ \sum_{m=1}^{N_n} \left\| R_{n,2\rho(k+1)}f(m,\tilde{J}_{m,S})R_{n,2\rho(k+1)} \right\|_\infty, \quad (6.20) \]

is also bounded \( n \). Hence, by inserting these identities in the conclusion of Corollary 5.6 we proved the statement. \( \square \)

### 6.5 Proof of Theorem 2.7

**Proof of Theorem 2.7.** The proof is exactly the same as the proof of Theorem 2.3, with the only difference that we now rely on (the proof of) Theorem 2.6 and use Corollary 5.11 in the final step instead of Corollary 5.8. \( \square \)

### 6.6 Proof of Theorem 2.9

The proof of Theorem 2.9 also follows the same arguments. We start with the following adjustment of Lemma 6.2.

**Lemma 6.4.** Assume there exists a compact set \( E \subset \mathbb{R} \) such that

1. \( S(\mu_m^{(n)}) \subset E \) for \( m = 1, \ldots, N_n \) and \( n \in \mathbb{N} \),
2. for \( k \in \mathbb{N} \), we have

\[ \sup_{m=1,...,N_n} \int_{\mathbb{R}\setminus E} |x|^k K_{n,N}(m,x,m) \mathrm{d}\mu_m^{(n)}(x) = o(1/n), \]

as \( n \to \infty \).

Then for any function \( g \) such that \( x \to g(t,x) \) is a continuously differentiable function with at most polynomial growth at \( \pm \infty \), i.e \( g(t,x) = O(|x|^M) \) as \( |x| \to \infty \), for some \( M \) independent of \( t \in I \), we have

\[ \text{Var} X_n(f) \leq \frac{N}{2} \sum_{m=1}^{N} \left( t_{m+1}^{(n)} - t_m^{(n)} \right)^2 \left\| \frac{\partial g}{\partial x} \right\|_{L_\infty(I \times E)}^2 \sup_{m=1,...,N_n} \| [P_n, J_m] \|_2^2 + o(1), \]

\[ (6.21) \]
as \( n \to \infty \).

**Proof.** We use the same arguments as in the proof of Lemma 6.2. The only possible issue that we need to address is that in (6.7) the constant in the \( o(1) \) term may depend on \( N \) and hence, in the present situation, also on \( n \). However, by the fact we take the supremum over \( m \) in (6.21) we have that the constant in the \( o(1) \) terms in (6.10) and (6.11) can be chosen such that they do not on \( n \). By following the same proof we see that the constant in the \( o(1) \) does not depend on \( n \) and hence we have

\[
\text{Var} X_n(f) \leq \frac{N_n}{2} \sum_{m=1}^{N_n} \sup_{x \in E} \left\| \frac{\partial f}{\partial x}(m, x) \right\|^2 \|[P_n, J_m]\|_2^2 + o(1),
\]

as \( n \to \infty \). Since \( f \) is considered to be of the special type (2.24), we rewrite the latter in terms of \( g \),

\[
\text{Var} X_n(f) \leq \frac{N_n}{2} \sum_{m=1}^{N_n} \left( t^{(n)}_{m+1} - t^{(n)}_m \right)^2 \left\| \frac{\partial g}{\partial x} \right\|_{L_\infty(I \times E)}^2 \|[P_n, J_m]\|_2^2 + o(1),
\]

as \( n \to \infty \). The statement now follows by estimating the summands in terms of their supremum.

**Lemma 6.5.** Let \( a^{(m)}_0 \) and \( a^{(m)}_1 \) be piecewise continuous function on \( I \) for \( m = 1, \ldots, N_n \). Then for any real valued function \( g \) on \( \{1, \ldots, N\} \times \mathbb{R} \) such that \( x \mapsto g(\tau, x) \) is continuously differentiable, we have that

\[
\sigma(g)^2 = \sum_{k=1}^{\infty} \int I \times I e^{-|\tau_1(t) - \tau_2(t)|k} g_k(t_1) g_k(t_2) dt_1 dt_2,
\]

is finite, where

\[
g_k(t) = \frac{1}{2\pi} \int_0^{2\pi} g(m, a_0(t) + 2a_1(t) \cos t) e^{-i k \theta} d\theta.
\]

Moreover, for some constant \( C \) we have

\[
\sigma(f)^2 \leq C \left\| \frac{\partial g}{\partial x} \right\|_{L_\infty(F)}^2,
\]

where \( F = \{(t, x) \mid x \in [a_0(t) - 2a_1(t), a_0(t) + 2a_1(t)], \ t \in I\} \).

72
Proof. As in (2.28) we rewrite $\sigma(g)^2$ as

$$\sigma(g)^2 = \frac{1}{\pi} \sum_{k=1}^{\infty} \frac{k^2}{\omega^2 + k^2} \left| \int_I e^{-i\omega\tau(t)} g_k(t) dt \right|^2 d\omega,$$

showing that $\sigma(g)^2$ is positive (if finite). By applying the Cauchy-Schwarz inequality to the integral over $t$, the estimate (6.13) and the Plancherel Theorem we have

$$\sigma(g)^2 \leq (\beta - \alpha) \pi \sum_{k=1}^{\infty} \int_{\mathbb{R}} k^2 |g_k(t)|^2 dt.$$

Then by integration by parts we find

$$kgf_k(t) = \frac{1}{2\pi} \int_0^{2\pi} \frac{\partial g}{\partial x}(t,a_0(t) + 2a_1(t) \cos \theta) a_1(t) \sin \theta \ e^{-ik\theta} d\theta.$$

By applying Parseval and estimating the $L_2$ norm by the $L_\infty$ norm, we find there exists a constant $C$ such that

$$\sum_{k=1}^{\infty} k^2 |g_k(t)|^2 \leq C \left\| \frac{\partial g}{\partial x} \right\|_{L_\infty(F)}^2,$$

and this finishes the proof. \qed

Proof of Theorem 2.9. The proof of is now identical to the proof of Theorem 2.9 with only difference being that we use Theorem 2.7, Lemma’s 6.4 and 6.5 instead of Theorem 2.3 and Lemma’s 6.2 and 6.3. \qed
