TYING UP LOOSE STRANDS: DEFINING EQUATIONS OF THE STRAND SYMMETRIC MODEL

COLBY LONG AND SETH SULLIVANT

Abstract. The strand symmetric model is a phylogenetic model designed to reflect the symmetry inherent in the double-stranded structure of DNA. We show that the set of known phylogenetic invariants for the general strand symmetric model of the three leaf claw tree entirely defines the ideal. This knowledge allows one to determine the vanishing ideal of the general strand symmetric model of any trivalent tree. Our proof of the main result is computational. We use the fact that the Zariski closure of the strand symmetric model is the secant variety of a toric variety to compute the dimension of the variety. We then show that the known equations generate a prime ideal of the correct dimension using elimination theory.

1. Introduction

The strand symmetric model is a phylogenetic model designed to reflect the symmetry inherent in the double-stranded structure of DNA. This symmetry naturally imposes restrictions on the transition probabilities assigned to each edge and imposing only these restrictions gives the general strand symmetric model (SSM). The phylogenetic invariants of a model are algebraic relationships that must be satisfied by the probability distributions arising from the model. Their study was originally proposed as a method for reconstructing phylogenetic trees [4, 10], but they have also been useful theoretical tools in proving identifiability results (see e.g. [2]). Results in [6] imply that to determine generators of the ideal of phylogenetic invariants for any trivalent tree, it suffices to determine them for the claw tree, $K_{1,3}$.

Though the general strand symmetric model itself is not group-based, Casanellas and the second author [3] showed that it is still amenable to the Fourier/Hadamard transform technique of [7, 11]. In the Fourier coordinates, it becomes evident that the parameterization of the model for $K_{1,3}$ is a coordinate projection of the secant variety of the Segre embedding of $\mathbb{P}^3 \times \mathbb{P}^3 \times \mathbb{P}^3$. From this observation, the same authors were able to find 32 degree three and 18 degree four invariants of the homogenous ideal for $K_{1,3}$ and to show that these invariants generate the ideal up to degree four. Whether or not these equations generate the entire ideal was heretofore unknown.

In this paper, we show that these 50 equations in fact generate the entire ideal of the SSM for $K_{1,3}$. First, we use the parameterization of the model after the matrix-valued Fourier transform and the tropical secant dimension technique of Draisma [5] to determine the dimension of the variety of probability distributions arising from the model. Then, using Macaulay2 [9], we show that the ideal generated by these fifty equations defines a variety of the same dimension. Finally, with the aid of symbolic computation we generate a decreasing sequence of elimination ideals demonstrating that the ideal in question is prime. Thus, the variety defined by these equations is irreducible, contains the parameterization, and is of the same dimension as the parameterization, from which the result follows.

2. Phylogenetic Invariants of the SSM Model

2.1. Preliminaries. The general strand symmetric model on an $n$-leaf rooted tree $T$ is a phylogenetic model of 4-state character change. Since the SSM is specifically intended to model DNA evolution, we associate to each node $v$ of the tree a random variable $X_v$ with state space
corresponding to the DNA bases \{A,C,G,T\}. Associated to each edge is a $4 \times 4$ transition matrix with rows and columns indexed by the bases. The entry $\theta_{ij}$ encodes the probability of changing from character $i$ to $j$ along that edge. In the double helix structure of DNA it is always the case that the bases $A$ and $T$ are paired together and likewise for $C$ and $G$. So that our model reflects this strand symmetry, we let $\pi = (\pi_A, \pi_C, \pi_G, \pi_T)$ be the distribution of the bases at the root, and set $\pi_A = \pi_T$ and $\pi_C = \pi_G$. Additionally, since a character transition in one strand will induce a corresponding transition in the other, we insist

$$\theta_{AA} = \theta_{TT}, \theta_{AC} = \theta_{TG}, \theta_{AT} = \theta_{TA}, \theta_{CA} = \theta_{GT}, \theta_{CC} = \theta_{GG}, \theta_{CG} = \theta_{GC}, \theta_{CT} = \theta_{GT}.$$ 

The key observation from [3] is that the SSM is a matrix-valued group-based model. Identify the character states of the random variables of a phylogenetic model with elements of $G \times \{0, \ldots, l\}$ where $G$ is a finite abelian group. Then each character state is indexed by an element $(\overline{i})$ where $j \in G$ and $i \in \{0, \ldots, l\}$. In these indices, the entries of the transition matrix along edge $E$ are written $E_{i_1i_2}^{j_1j_2}$ and the probability that the root is in state $(\overline{i})$ is equal to $R_i^j$.

**Definition 2.1.** A phylogenetic model is a matrix-valued group-based model if for each edge, the matrix transition probabilities satisfy

$$E_{i_1i_2}^{j_1j_2} = E_{i_1i_2}^{k_1k_2}$$

whenever $j_1 - j_2 = k_1 - k_2$ and the root distribution probabilities satisfy $R_i^j = R_{i'}^j$.

Let $G = \mathbb{Z}_2$ and $l = 1$, then the following identifications make manifest the matrix-valued group-based structure of the SSM: $A = (\overline{0}), C = (\overline{1}), G = (\overline{1}), T = (\overline{1})$.

The tree parameter of an algebraic model determines a polynomial map sending each choice of stochastic parameters into the probability space indexed by $n$-tuples of the characters. Thus, for the SSM of a tree $T$, we have the following map

$$\phi_T : S_T \rightarrow \Delta^{4n-1}.$$ 

If we do not impose the stochastic conditions on the parameters then $\text{im}(\phi_T)$, where the closure is taken in the Zariski topology, is a variety. In Section 16.1 of [3], the authors detail the group-valued Fourier transform and show how it can be used to obtain a simple parameterization for the closure of the cone over the SSM for $T = K_{1,3}$, denoted $CV(T)$. Letting $q_{ijk}^{mno}$ be the transformed coordinates of the image space, we have

$$\psi : q_{ijk}^{mno} = d_{0i}^{mn} e_{0j}^{nn} f_{0k}^{oo} + d_{1i}^{mn} e_{1j}^{nn} f_{1k}^{oo}$$

if $m + n + o \equiv 0$ in $\mathbb{Z}_2$, and $q_{ijk}^{mno} = 0$ otherwise. Now to determine the defining equations for the SSM for $K_{1,3}$, it is enough to determine the defining equations for $\text{im}(\psi_T) = CV(T)$. Let $I$ be the ideal generated by the fifty equations found in [3], the rest of the paper will be concerned with proving the following theorem.

**Theorem 2.2.** The vanishing ideal of the strand symmetric model for the graph $K_{1,3}$ is minimally generated by 32 cubics and 18 quartics. The ideal has dimension 20, degree 9024, and Hilbert series

$$1 + 12t + 78t^2 + 332t^3 + 984t^4 + 1908t^5 + 2394t^7 + 1908t^8 + 984t^9 + 332t^{10} + 78t^{11} + 12t^{12} + t^{13}. \quad (1 - t)^{20}$$

Note that the Hilbert series suggests that the ideal is Gorenstein though we have not been able to prove this.
2.2. Dimension. A toric variety is a variety that is parametrized by monomials. Let $C \subset CV(T)$ be the toric variety parameterized in each coordinate only by the monomial containing variables with zero in the first entry of the subscript. With this definition, $CV(T)$ is the secant variety $C \ast C$ and so we can use existing techniques from [5] for computing the dimensions of secant varieties.

The theorem from [5] which we wish to apply is conveniently formulated for our purposes by Theorem 15 from [1]. We associate to each monomial $x_1^{u_1}x_2^{u_2}\ldots x_n^{u_n}$ in the parameterization of a toric variety an integer vector $u$ and let $A$ be the set of these integer vectors. Let $H = \{x \in \mathbb{R}^d : c^T x = e\}$ be a hyperplane in $\mathbb{R}^d$ that splits $\mathbb{R}^d$ into two components which we will label $H^+ = \{x \in \mathbb{R}^d : c^T x > e\}$ and $H^- = \{x \in \mathbb{R}^d : c^T x < e\}$.

In our case, the matrix $A$ is a $12 \times 32$ matrix of rank 10, with each column containing exactly threes 1’s and nine 0’s. If we let $\{e_0^1, e_0^2, e_1^1\}$ denote the standard basis in $\mathbb{R}^2 \times 2$ then the thirty-two columns of $A$ are

$$\{e_0^m \oplus e_j^n \oplus e_k^o \in \mathbb{R}^{12} : m + n + o = 0 \in \mathbb{Z}_2\}.$$ 

Theorem 2.3. [1] Theorem 15] Let $V_A$ be a projective toric variety with corresponding set of exponent vectors $A \subset \mathbb{N}^d$. Let $H$ be a hyperplane not intersecting $A$. Let $A^+ = A \cap H^+$ and $A^- = A \cap H^-$. Then $\dim(V_A \ast V_A) \geq \dim(V(I)) = 20$.

Lemma 2.4. $\dim(CV(T)) = \dim(V(I)) = 20$.

Proof. Regard $C$ as a projective variety so that $C = V_A$ from Theorem 2.3. The hyperplane defined by the vector $c = (1,1,0,0,1,1,0,0,1,1,0,0)$ and $e = \frac{3}{2}$ gives $|A^+| = |A^-| = 16$ and rank($A^+$) = rank($A^-$) = 10. Therefore, by Theorem 2.3 as a projective variety $\dim(C \ast C) \geq 19$ and as an affine cone $\dim(CV(T)) \geq 20$. Using Macaulay2 we determine that $\dim(V(I)) = 20$, and since $CV(T) \subseteq V(I)$, we must have $\dim(CV(T)) = 20$. \qed

2.3. Primality. In this section we outline our approach for determining if the ideal $I$ is prime.

There are algorithms for determining whether or not an ideal is prime implemented in many computer algebra systems. However, these algorithms do not terminate for many of the large ideals confronted in practice, including the ideal $JC$ and since Lemma 2.5.

Proposition 23 of [8] was stated without proof, so we include a proof of the result for completeness.

Proof. ($\Rightarrow$) It is true in general that the elimination ideal of a prime ideal is prime. Suppose $J$ is prime and let $a, b \in k[x_1, \ldots, x_n] \setminus J_1$ such that $ab \notin J_1$. Since $J_1 \subset J$, it must be that either $a$ or $b$ is in $J \setminus J_1$, otherwise it would contradict that $J$ is prime. Therefore, either $a$ or $b$ is in $k[x_1, \ldots, x_n] \setminus k[x_2, \ldots, x_n]$ and so $ab$ must have some term that involves $x_1$, which implies $ab \notin J_1$, a contradiction.

($\Leftarrow$) Suppose $J_1$ is prime but that $J$ is not. Then there must exist $a, b \in k[x_1, \ldots, x_n] \setminus J$ with $ab \in J \setminus J_1$. Choose $a$ and $b$ so that $ab$ has minimal $x_1$-degree among all such pairs. Let $d$ be the $x_1$-degree of $a$ and $d'$ the $x_1$-degree of $b$. Since $ab \in J \setminus J_1$, $d + d' \geq 1$, and so without loss of generality we can assume $d \geq 1$. Write

$$a = h_0 + h_1x_1 + h_2x_1^2 + \ldots + h_dx_1^d,$$

where each $h_i \in k[x_2, \ldots, x_n]$ and $h_d \neq 0$. Then since $f \in J$ and $g$ is not a zero divisor mod $J$, $a' := (ga - h_dx_1^{d-1}f)$ is not in $J$ and has $x_1$-degree strictly less than $d$. It follows that $a'b$ has
\[ x_1 \text{-degree strictly less than that of } ab. \] Finally, since \( ab \) and \( f \) are in \( J \), \( a'f = gab - h_d x_1^{d-1} fb \) is in \( J \), contradicting the minimality of the \( x_1 \)-degree of \( ab \).

**Lemma 2.6.** The ideal \( I \) generated by the 32 cubics and 18 quartics of the general strand symmetric model for \( K_{1,3} \) is prime.

**Proof.** The proof is obtained by repeated application of Lemma 2.5 The computations we describe can be found at

http://www4.ncsu.edu/~smsulli2/Pubs/LooseStrandsWebsite/SSM_Supplement.html

in the Macaulay2 file SSM_Supplement where the symbols 0, 1, 2, and 3 are substituted for \( \left( \frac{1}{1}, \frac{1}{0}, \frac{0}{1}, \frac{0}{0} \right) \).

First, we let \( I_0 = I \). Beginning with \( k = 1 \), we find a polynomial \( f_k = g_k x_k + h_k \in I_{k-1} \), verify that \( g_k \) is not a zero-divisor mod \( I_{k-1} \), and then eliminate the corresponding variable to obtain the ideal \( I_k \). In this way we generate a decreasing chain of elimination ideals

\[ I = I_0 \supset I_1 \supset I_2 \ldots \supset I_{10}. \]

Using the `isPrime` function in Macaulay2, we show that \( I_{10} \), and hence every ideal in the sequence, is prime.

While this is the general outline of our approach, it is actually computationally easier to show that none of the \( g_k \) that we encounter is a zero-divisor mod the respective elimination ideal first. Identify the new indices 0, 1, 2, and 3 with the set of standard basis vectors \( \{ e_1, e_2, e_3, e_4 \} \) and define a multi-grading where the weight of \( q_{ijk} \) is \( e_{i+1} \oplus e_{j+1} \oplus e_{k+1} \). Let \( q_{ij} q_3 - q_3 q_{i}q_3 \) be a nontrivial binomial that is homogenous with respect to this grading. As it so happens, we are always able to choose \( f_k = g_k x + h_k \) so that \( g_k \) is either a binomial of this form or a product of binomials of this form. There are two elementary observations that will be useful:

1. \( g = l_1 l_2 \) is a zero-divisor mod \( J \) if and only if at least one of \( l_1 \) and \( l_2 \) is.
2. \( g \) is not a zero-divisor mod any elimination ideal of \( J \) if it is not a zero-divisor mod \( J \).

Thus, to show that none of the \( g_k \) is a zero-divisor mod \( I_{k-1} \) it is enough to show that none of the homogenous binomials is a zero-divisor mod \( I \).

The symmetry of \( I \) enables us to establish this by considering only a small subset of the homogenous binomials. There is a group action of \( S_4 \times S_4 \times S_3 \times S_3 \) on \( Sec^2(\text{Seg}(\mathbb{P}^3 \times \mathbb{P}^3 \times \mathbb{P}^3)) \), that comes from performing the rank-preserving column and transposition operations. Hence, the same group acts on \( I(\text{Sec}^2(\text{Seg}(\mathbb{P}^3 \times \mathbb{P}^3 \times \mathbb{P}^3))) \), where column operations correspond to interchanging the symbols in the indices of the variables and transposition operations correspond to permuting the order of the indices of each variable. Let \( G \) be the subgroup of elements of \( S_4 \times S_4 \times S_3 \times S_3 \) satisfying \( g \cdot q_{ijk}^{mn} = q_{ij}^{m'n'o'} \) with \( m + n + o \equiv m' + n' + o' \) in \( \mathbb{Z}_2 \) for each of the 64 variables. Since

\[ I(CV(T)) = I(\text{Sec}^2(\text{Seg}(\mathbb{P}^3 \times \mathbb{P}^3 \times \mathbb{P}^3))) \cap \mathbb{C}[q_{ijk}^{mn} : m + n + o = 0], \]

\( G \) acts on \( I(CV(T)) \), and since the generators of \( I \) generate \( I(CV(T)) \) up to degree four, \( G \) acts on \( I \) as well. Let \( H \) be the subgroup of \( G \) generated by elements that correspond to interchanging symbols in the indices. For example, \( h = ((01), (01)(23), (01)) \in H \) interchanges 0 ↔ 1 in the first index, 0 ↔ 1 and 2 ↔ 3 in the second, and 0 ↔ 1 in the third so that \( h \cdot (q_{02113013} q_{013q121}) = (q_{13003} q_{103q30}). \) Then

\[ H = \left\{ ((01), id, id), (id, (01), id), (id, (01), (01)), ((23), id, id), (id, (23), id), (id, id, (23)), ((0213), (0213), id), ((0213), (0213), (0213)) \right\} \]

is a 256-element normal subgroup and \( G \cong H \times S_4 \). The set of homogeneous binomials partitions into three orbits under the action of \( G \). In the file SSM_Supplement we show that none of the
homogeneous binomials is a zero-divisor by showing that one representative of each of the orbits under the group action is not a zero-divisor.

Having shown that $I$ is prime, we are able to give a short proof of Theorem 2.2.

Proof of Theorem 2.2. The containment $I \subseteq I(CV(T))$ implies that $CV(T) \subseteq V(I)$. By Lemma 2.6, $I$ is prime and so $V(I)$ is an irreducible variety. By Lemma 2.4, $CV(T)$ is an irreducible variety contained in an irreducible variety of the same dimension, so $CV(T) = V(I)$ and $I = I(CV(T))$. Knowing explicit generators of the vanishing ideal of the strand symmetric model for the graph $K_{1,3}$, the claims about the rank, degree, and Hilbert Series of the ideal are easily verified by the Macaulay2 code in SSM_Supplement. □
