Keywords: Silver Nanoparticles; Common Sage (Salvia Officinalis); Biosynthesis; Antimicrobial Activity; Antioxidant Activity

Abstract

The aim of the present study is the biosynthesis of silver nanoparticles using the aqueous extract of the common sage (scientific name: salvia officinalis) leaf, and investigating their antioxidant and antimicrobial activities. In order to synthesize the silver nanoparticles, aqueous extract of the plant was prepared and introduced into a 1 mM silver nitrate solution. Antioxidant activity of the synthesized nanoparticles was examined based on the 1-diphenyl-2-picrylhydrazyl (DPPH) radical absorbance, while the antimicrobial activity of the nanoparticles was evaluated by determining minimum inhibitory concentration (MIC) against three bacterial species: E. coli O157:H (43895), S. typhimurium (ATCC 35987), and L. monocytogenes (ATCC 7644). With a spherical geometry and average particle size of 30 – 50 nm, the synthesized silver nanoparticles exhibited the maximum absorbance at 430 nm. In this study, the manufactured silver nanoparticles were used as inhibitory agents for the DPPH radicals (IC50 = 170 μM). The MIC of the silver nanoparticles against the experimental pathogens was found to range from 3.6 to 12.25 μg/mL. Among other pathogens, the monocytogenes exhibited the highest value of MIC. The obtained results indicated suitable antioxidant and antibacterial activities of the biosynthesized nanoparticles.

Introduction

The oxidative stress is a result of misbalance between the production of free radicals and the metabolism reactions that end up damaging the lipids, proteins, and nucleic acids. Such damages may arise due to either low level of antioxidants or excessive production of free radicals in the body. In human beings, the oxidative stress is associated with the emergence of chronic diseases such as diabetes and cancer. Accordingly, the production of synthetic and naturally occurring antioxidants is necessary to prevent the oxidative stress and its adverse impacts. The antioxidants can effectively attenuate the adverse impacts of the free radicals in the biologic system and foodstuff via number of different mechanisms, thereby contributing to detoxification. In this respect, one can use the nanoparticles with antioxidant effects that are synthesized through green synthesis method (where plant sublayers are used to prepare environment-friendly nanoparticles, including no harmful chemical compound). Currently, the use of non-toxic precursors for the synthesis of nanoparticles is largely regarded for preventing biological hazards, especially in medical and pharmaceutical applications, so that many researchers are focused on the active biomaterials obtained from plants or other sources such as bacterial, fungal, and yeasts for the synthesis of nanoparticles. The green synthesis method is believed to enhance the biocompatibility and performance of metal nanoparticles for biological applications thanks to the elimination of the adverse chemical compounds.

When it comes to the biosynthesis of the nanoparticles, it is more advantageous to do that in an extracellular fashion using plants or their extracts, as this synthesis process can be controlled to obtain nanoparticles of particular particle size, particle size distribution, and particle geometry for specific applications. As of present, biosynthesis of silver nanoparticles has been undertaken with various plants, including Acalypha indica [1], Artemisia nilagirica [2], Ocimum sanctum [3], Piper longum [4], Azadinachta indica, Catharanthus roseus [5], and many others. Moreover, various reports have highlighted the biological characteristics of the biosynthesized silver nanoparticles including antimicrobial, antioxidant[6], and anticancer effects. The studies on the antioxidant
effects of the silver nanoparticles obtained from various plant species (e.g. Canthium coromandelicum, Terminalia, Rosmarinus officinalis, Syzygium cumini (L), Cassia, Dalbergia rostrate, and Fraxinus excelsior fistula) have confirmed the antioxidant activity of the silver nanoparticles. Resistance to human pathogens is a major challenge in the pharmaceutical and medical applications. This antibiotic resistance together with excessive and consistent use of chemical drugs contribute to the resistance of the microorganisms. Another disadvantage of using these drugs has been their increased side-effects of them that may cause parasites and/or recurrence of Multidrug-Resistant Pathogens (MRDs) of the diseases that are even more dangerous than the initial disease [7-10].

Accordingly, modification of antibacterial compounds to improve their antibacterial potentials has been an important and priority sector of the research in recent years. The silver has long been acknowledged for its antibacterial activity. Releasing silver ions, the silver nanoparticles exhibit antibacterial effect against both aerobic and anaerobic bacteria. The silver nanoparticles represent colonies of silver atoms with a final diameter of 100 nm. These can enter the bacteria by getting attached to the sulfur-bearing proteins on the surface of the membrane of the bacteria, where they trigger changes in the morphology, membrane permeability, and the cellular respiration and reproduction chain, leading to a cell death. Indeed, the main reason behind the widespread use of silver nanoparticles is their antibacterial activity, so that one can come with an antibacterial coating by adding small amounts of these nanoparticles to the coating and hence eliminate the pollution [10-14]. So far, silver nanoparticles have been used by various medicinal herbs, including Aegle Acacia leucophoea, Solanum trilobatum, Syzygium marmelos, cumini, Centella asiatica, and Citrus sinensis. Biosynthesis of silver nanoparticles from the common sage extract and evaluation of their antioxidant and antimicrobial activities have been performed in the food industry to retain more of the nutrients along with the original taste and smell while reducing the food spoilage rate, where nanomaterial coatings with antimicrobial and antioxidant effects are utilized.

Khandelwal et al. synthesized the silver nanoparticles using the leaves of Argimone maxican, ending up with 20-nm particles with inhibitory effects against many bacteria and fungi. In their study, Govindaraju et al. undertook the biosynthesis of silver nanoparticles using Solanum tovum and obtained nanoparticles of 14 nm in diameter and good inhibitory effects against the growth of bacteria such as Pseudomonas, Aspergillus, Staphylococcus aureus, aeruginosa, and Aspergillus niger flavus. Therefore, the present research attempts to evaluate the antioxidant and antimicrobial activity of the silver nanoparticles that are obtained from the aqueous extract of the common sage. Accordingly, should the activities fall in a good range, compared to the other nanoparticles synthesized with plant extracts, one can proceed to complementary research works for actually using these nanoparticles in the modern technologies adopted in the food industry.

Material and Method

Chemicals and Microorganisms

All of the chemicals used in this study were prepared at high purities. Silver nitrate salt (AgNO₃), hydrochloric acid (HCl), and sodium hydroxide (NaOH) were procured from Merck Co (Germany), and the used microorganisms (including E. coli 0157:H (43895), S. typhimurium (ATCC 35987), and L. monocytogenes (ATCC 7644) were obtained from Iranian Research Organization for Science and Technology. Double-distilled water was used for washing and solution preparation.

Preparing the Extract

The common sage plant was collected from Kashmar (Khorasan Razavi Province, Iran). Upon investigating the herb according to the herbarium at Ferdowsi University ( Mashhad, Iran), it was confirmed to be Salvia officinalis. Some leaves of the plat were washed with the double-distilled water and dried in dark at room temperature. The dried leaves were then powdered using an electrical grinder. The so-called soxhlet method was used to obtain the extract for the synthesis of the nanoparticles. The extract was then filtered using a Whatman No. 24 filter paper. In order to remove the suspended particles in the extract completely, the sample was subjected to centrifugation on a Sorvall Superspeed RC2-B (England) at 1000 RPM for 10 minutes [15-20].

Synthesis of the Nanoparticles

In order to synthesize the silver nanoparticles, 2 mL of the extract was added to 4 mL of a 1 mM silver nitrate solution. A color change from light yellow to dark brown indicated the synthesis of the nanoparticles. The process was performed at pH = 7 and a temperature of 40°C.

Silver Nanoparticles Characterization

The color change was objectively observed on the samples. Furthermore, absorbance spectra were measured in the range of 400 – 700 nm using a Biotech EPOCH (United States) spectrophotometry apparatus. Further characterization was performed using a Philips CM-120 electron scanning microscopy to identify the geometry and size of the synthesized particles [21-23].

Investigation of DPPH Radical Removal Potential

The respective assay was a modified version of that presented by Johnssona et al. For this purpose, 0.5 mL of 0.1 mM DPPH was prepared and introduced into 95% ethanol with 100µL of the solution of the silver nanoparticles synthesized using the common sage extract (i.e. standard solution). The resultant solution was placed in dark at 38°C for 31 minutes, followed by reading the absorbance spectra at a wavelength of 518 nm. In order to compare the activity of the silver nanoparticles synthesized from the aqueous extract of the common sage leaves, the reduced glutathione (GSH) standard was used as an IC50 IC standard antioxidant [24-28]. In order to determine the required concentration for inhibiting 50%
Results and Discussion

In the synthesis of the silver nanoparticles using the aqueous solution of the common sage leaves, the plant served as a reducing agent and stabilizer: Figure 1 show the color change of the silver nanoparticle solution and the respective UV-vis spectrophotometry spectra. The appearance of the dark brown color upon the reaction with the silver ion provides a clear indication of the reduction of the metal ions and formation of the silver nanoparticles in the medium. Formation of precipitates along with the color change indicates that the manufactured particles are large in size, while a color change without any precipitation reveals that the synthesized particles are so small (favorable). In the present study, the color change occurred with no precipitation. The basic mechanism driving the synthesis of nanoparticles is the reduction of the ions in the salts (i.e. cancelling the electrical charge). In this research, this process took 30 minutes at 40°C to complete, marking the fastness of this methodology and its feasibility at moderate temperatures, rather than high temperatures. The color change of the colloid silver nanoparticles from yellow to brown is a result of a phenomenon called Plasmon [34-37].

Upon observing the Surface Plasmon Resonance (SPR) of the color change, the synthesis of the nanoparticles was further confirmed by the spectrophotometry studies. Figure 1 shows the results of UV-vis spectrophotometry on the treated aqueous extract of the common sage following the synthesis of the silver nanoparticles. The maximum absorbance peak on the curve obtained for the solution containing the biosynthesized nanoparticles using the aqueous extract of the common sage was observed at a wavelength of 430 nm, indicating successful synthesis of the nanoparticles. Tanks to the particle SPR, the spectrophotometry method can be used to track the synthesis of silver nanoparticles in the plant extract medium. The absorbance peak of the silver nanoparticles occurs at a wavelength of about 430 nm, with possible shifts due to the actual conditions and particle size. The size, geometry, and size distribution of the synthesized silver nanoparticles were investigated on the SEM apparatus. Figure 2 shows an image of the silver nanoparticles recorded by Transmission Electron Microscopy (TEM), providing some information about the morphology and size of the silver nanoparticles, the SEM images show that the obtained nanoparticles were almost entirely spherical, with their size ranging from 30 to 50 nm on average. Investigations performed in the present research showed that the extract of the common sage leaves offers large potentials for the synthesis of silver nanoparticles. Following the proposed methodology, the nanoparticles could be manufactured in stages, with the process being cost-effective and relatively fast.
Figure 1: UV-vis spectrum of the silver nanoparticles biosynthesized with the aqueous extract of common sage leaves.

Figure 2: Antioxidant activity of the nanoparticles biosynthesized with the aqueous solution of common sage using the DPPH method, where the GSH is used as a standard. Data are reported in the form of mean ± standard deviation.

The color change from transparent to brown and the increase in the absorbance of the solution were due to the reducing function of the silver ions and their agglomeration to form the silver nanoparticles. The common sage contains numerous natural compounds including antioxidants, phenols, and flavonoids; all of these compounds effectively contribute to the reduction of the metal ions and their conversion to nano-metric metal atoms and stabilization of the synthesized nanoparticles. In this study, the DPPH radical inhibitory activity of the silver nanoparticles biosynthesized with the aqueous solution of common sage was evaluated by increasing the concentration of the DPPH. Accordingly, it was observed that the radical elimination increased with increasing the concentration of the nanoparticles. As can be seen, some 50% of the free radicals were inhibited at a nanoparticle concentration of 464 μM. Particular plants have the potentials for preparing new antioxidant silver nanoparticles via the green methodology. The potential ability of these plants for biosynthesis (reduction) of Ag+ to Ag0 has been identified using spectrophotometry techniques, indicating antioxidant property of the nanoparticles produced via this procedure.

Considering the necessity of identifying both synthetic and naturally occurring antioxidants for preventing the oxidative stress and its adverse impacts, the present research seeks, among other, to characterize the silver nanoparticles synthesized from the aqueous extract of the common sage leaves. In a study performed on the nanoparticles produced using ornamental plants (Hyacinthus orientalis L. and Dianthus caryophyllus L.), the luminescence-based quantitative methods were used to investigate the antioxidant characteristics of the nanoparticles. Accordingly, the silver nanoparticles exhibited higher levels of antioxidant, as compared to the plant extract alone. Moreover, the nanoparticles of finer particle sizes were found to be more efficient antioxidants that those of coarser particles. In a study, antioxidant activity of the silver nanoparticles produced from the leaf extract of Artemisia annua and Sida acuta was investigated under lab conditions. In this study, the DPPH, as a free radical, received an electron or hydrogen radical to transform into a stable molecule. Reduced absorbance at 517 nm and the color change from purple to yellow showed that the silver nanoparticles produced from the mentioned plants had the ability to transform the hydrogen into an oxidant, thereby
Results of this study further showed that the antioxidant activity of the samples was linked to their concentration, i.e. the antioxidant activity increased with concentration. Compared to standard antioxidant (ascorbic acid), the silver nanoparticles showed very good antioxidant activity. In another study, the antioxidant activity of the silver nanoparticles obtained from the extract of the Chenopodium mural leaves was evaluated using the DPPH assay. Accordingly, the inhibitory power of the nanoparticle was evaluated as 13.27 ± 0.12 at a nanoparticle concentration of 5 mg/L and then increased to 65.43 ± 0.18 by increasing the concentration to 20 mg/L. This highlighted that the antioxidant activity is associated with the silver nanoparticles concentration. In another piece of research, antioxidant activity of the silver nanoparticles synthesized from Morinda pubescens was investigated by their inhibitory effects against DPPH, superoxide, and hydroxyl radicals. Based on the DPPH assay, a dosage-dependent color change from purple to yellow with an IC50 of 84 ± 2.65 mg/L showed that the sample contained nanoparticles of high antioxidant activity.

In another work, investigations were performed on the antioxidant activity of the silver nanoparticles obtained from the Piper longum fruit using their inhibitory effects against free radicals of DPPH, superoxide, nitric oxide, and hydrogen peroxide. Average inhibitory effect of the silver nanoparticles on the mentioned radicals were evaluated as 67% at nanoparticle concentrations ranging from 100 – 600 µg/mL, 60% at nanoparticle concentrations ranging from 100 – 200 µg/mL, 70% at nanoparticle concentrations ranging from 50 – 500 µg/mL, and 96% at nanoparticle concentrations ranging from 10 – 60 µg/mL, respectively. Another study focused on the antioxidant activity of the gold and silver nanoparticles synthesized from the Prunus armeniaca extract. In this study, concentration-dependent antioxidant activity of the nanoparticles was evaluated through DPPH radical and 2,2’-azinobis (3-ethylbenzothiazoline-6-sulphonic acid) (ABTS) inhibition assays. Based on the results, IC50 of the gold and silver nanoparticles for the DPPH assay were 11.27 and 16.18 mg, and the corresponding values to the ABTS assay were 3.40 and 7.12 mg, respectively. That is, the silver nanoparticles showed higher antioxidant activity than the gold nanoparticles. In both cases, an increase in the concentration of the nanoparticles added to their antioxidant activity [38].

The above mentioned studies show that an increase in the concentration of the nanoparticles mixed with different plant extracts results in an antioxidant effect; in some cases, these nanoparticles provided for antioxidant effects resembling or even close to that of standard antioxidants. Similar to the results of the abovementioned studies, the present study shows that the silver nanoparticles biosynthesized from the aqueous extract of the common sage offer good antioxidant effect. Among the pool of naturally occurring metals, the silver ions exhibit intensive antimicrobial effects against many bacterial strains. Compared to the silver ions, the silver nanoparticles can be good antimicrobial agents due to their large specific surface area (surface-to-volume ratio) and unique physiochemical properties. In fact, the main reason behind the largely superior antibacterial effect of the silver nanoparticles over the silver is the large surface-to-volume ratio of the silver nanoparticles, which intensifies the impact of the silver nanoparticles on the bacteria. In this study, once finished with synthesizing the silver nanoparticles, antibacterial activity of the synthesized particles was evaluated against three bacteria, namely Escherichia coli, Listeria monocytogenes, and Salmonella typhimurium. For this purpose, MIC and then MBC of the samples were examined, with the results presented in Table 1. Table 1 shows that the silver nanoparticles exhibited MIC value of 6.25 – 3.12 µg/mL against the studied pathogens. In addition, the Listeria monocytogenes, among the other bacteria studied in this work, showed the lowest sensitivity to the biosynthesized silver nanoparticles. The two gram-negative pathogens showed a MIC value of 3.12 µg/mL. Nevertheless, our studies showed the same value of MBC: 6.25 µg/mL.

| Bacterium               | MIC (µg/mL) | MBC (µg/mL) |
|-------------------------|-------------|-------------|
| Escherichia coli        | 3.12        | 6.25        |
| Listeria monocytogenes  | 6.25        | 6.25        |
| Salmonella typhimurium  | 3.12        | 6.25        |

In this study, the biosynthesized silver nanoparticles showed good antioxidant effect against all of the studied pathogens. The results of the MIC and MBC assays highlight the higher value of MIC for the Listeria monocytogenes, as compared to the other pathogens studied in this work, which might be linked to differences in the cell wall between different bacteria. Kim et al. reported that, as a gram-negative bacterium, S. aureus is more resistant to the nanoparticles, as compared to the E. coli. This is while the present study returned the same MBC value for all of the pathogens. It is worth mentioning that antibacterial activity of the nanoparticles depends on the nanoparticle size and concentration. In other reports, Shrivastava et al. (2010) and Guzman et al. (2012) investigated the antibacterial activity of the silver nanoparticles against different bacteria including E. coli, P. aeruginosa, and S. aureus. The suggested that although the antibacterial activity is dependent on the concentration, but the effect is more significant for gram-negative bacteria rather than the gram-positive ones. The difference in the response to the silver nanoparticles between the gram-negative and gram-positive bacteria could be attributed to the structural difference between their cell walls. Indeed, the gram-negative bacteria have thinner and hence weaker cell walls, and even more than that, the presence of a negatively-charged extracellular polysaccharide layer facilitates their interaction with the silver nanoparticles that are positively charged. Once a
nanoparticle is attached to the cell wall, it begins with penetrating through the cell membrane and then interrupts various metabolism and reproduction routes, causing a cell death.

**Conclusion**

Results of the present research showed that the common sages leaf extract has large potentials for synthesizing silver nanoparticles, providing a cost-effective yet relatively fast methodology for nanoparticle fabrication. The synthesized nanoparticles exhibited large potentials for reducing the metal ions and converting them to nano-metric metal atoms. According to the obtained results, the synthesized silver nanoparticles could act as a DPPH radical inhibitor (IC50 = 170 μm). Relatively high antioxidant activity of the silver nanoparticles biosynthesized from the aqueous extract of the common sage was further confirmed in this study, so that the MIC value of the silver nanoparticles against the tested pathogens fell in the range of 3.12 – 6.25μg/mL. In general, the results indicated appropriate antioxidant and antibacterial activities of the biosynthesized nanoparticles.
