Summary

Epidemiology studies and clinical trials have suggested that the use of non-steroidal anti-inflammatory drugs (NSAIDs), including aspirin, can significantly reduce the incidence of and mortality associated with many cancers [1–9], and upregulation of the COX2-PGE$_2$ pathway in tumor microenvironments might drive several aspects of cancer progression [4–6]. For these reasons, the mechanisms linking COX blockade and cancer prevention have long been an area of active investigation [7]. During carcinogenesis, COX-2 is expressed both by malignant epithelial cells [8, 9] and by tumor-associated stromal cells, including macrophages [10–12], but the observation that NSAIDs are most effective in cancer prevention in APC$^{min/+}$ mice if the mice are treated from conception [13] suggests that the COX-2/PGE$_2$ pathway might also be critical at the earliest stages of tumor development. In this study we take advantage of the translucency and genetic tractability of zebrafish larvae to investigate the involvement of inflammatory cells at cancer initiation, when transformed cells first arise in tissues. We previously showed that innate immune cells supply early transformed cells with proliferative cues [14] and, by using complementary pharmacological and genetic experiments, we now show that prostaglandin E$_2$ (PGE$_2$) is the trophic signal required for this expansion of transformed cells. Our in vivo observations at these early stages of cancer initiation provide a potential mechanistic explanation for why long-term use of low doses of NSAIDs, including aspirin, might reduce cancer onset.

Results and Discussion

We have used a human HRAS$^{G12V}$-driven transgenic zebrafish cancer model, in which mucous-secreting cells (analogous to human goblet cells) in the skin are transformed by an eGFP-HRAS$^{G12V}$ fusion protein. Using this model, we have previously shown with a live imaging approach that HRAS$^{G12V}$ (hereafter referred to as V12RAS)-expressing transformed cells induce a robust inflammatory response immediately after their emergence in host skin [14]. Paradoxically, the recruited innate immune cells play a trophic role in promoting the growth of transformed cells [14]. To test whether the COX-2/PGE$_2$ pathway might be involved in this process, we decided to block PGE$_2$ production.

Blocking PGE$_2$ Synthesis Retards the Growth of Transformed Cells

PGE$_2$ is one of the most abundant PGs produced in the body and plays key roles in mediating the inflammatory response [7, 15]. Cyclooxygenase 1 and 2 (COX-1 and COX-2) catalyze the rate-limiting step in PGE$_2$ synthesis by converting arachidonic acid into prostaglandin H$_2$, which is subsequently converted to prostaglandins (PGs) via the actions of specific PG synthases (Figure 1A). COX-1 is the housekeeping enzyme that generates PGE$_2$ under normal conditions. COX-2 is induced under inflammatory conditions and generates PGE$_2$ via mPGES at the site of immune cell recruitment (Figure 1A).

Zebrafish have three COX enzymes, zfCOX-1, zfCOX-2a, and zfCOX2-b [16, 17], and two PGE$_2$ synthases, cytosolic PGE$_2$ synthase (cPGES) and microsomal PGE$_2$ synthase (mPGES) [15]. Because zebrafish larvae are amenable to chemical treatment, we first took a pharmacological approach to suppress PGE$_2$ production (as outlined in Figure 1B). Suppression of COX-2 by either NS398 or Celecoxib led to a significant reduction in the number of V12RAS$^+$ cells (Figure 1C; Figure S1 in the Supplemental Information available online) without altering expression levels of endogenous kit a (the transgene driver) or having adverse effects on larval development (Figure S1). Moreover, ectopically added dmPGE$_2$ (a stable analog of PGE$_2$) partially restored the number of transformed cells in COX-2-inhibitor-treated larvae (Figures 1D and 1E; Figure S1). No significant reduction in the number of V12RAS$^+$ cells was seen in larvae treated with the COX-1 inhibitor SC560 (Figure 1C). These data suggest that in zebrafish, COX-2-mediated production of PGE$_2$ promotes the growth of transformed cells.

To establish whether PGE$_2$ was indeed the main tumor-promoting mediator generated by COX-2 in our model, we used CAY10560, another inhibitor specific to mPGES, which is known to be downstream of COX-2 in generating PGE$_2$ in zebrafish [18]. Again, we saw a reduction in the number of transformed cells; dmPGE$_2$ was able to restore the number of transformed cells in combined treatment with CAY10560 (Figure 1F).

Both V12RAS$^+$-Transformed Cells and Recruited Leukocytes Express COX-2, but Only Leukocytes Express mPGES

In mammals, both cancer cells and stromal cells can upregulate COX-2 [8–11], although the contribution of immune-cell-derived PGE$_2$ in tumor progression has not yet been defined [5]. We wanted to identify which cell lineages expressed PGE$_2$-generating enzymes at the earliest tumor-initiation stage. Double immunostaining showed that both V12RAS$^+$ cells (transformed cells) and most L-plastin$^+$ cells (neutrophils and macrophages) expressed COX-2 (Figures 1H and 1I). However, we could only detect a signal for mPGES antibody in a subset (approximately 20%) of the recruited leukocytes and in none of the transformed cells (Figures 1J and 1K). These expression profiles imply that, at this early stage, only leukocytes generate PGE$_2$.

Morpholino Knockdown of mPGES Expression Confirms that PGE₂ is Required for V12RAS⁺ Overgrowth

Our inhibitor data had demonstrated that COX-2-mPGES-derived PGE₂ was important for V12RAS⁺ cell growth. To confirm these findings, we used antisense morpholinos to genetically knock down PGE₂ production. Zebrafish have two genes encoding COX-2 but only one encoding mPGES. Moreover, mPGES only catalyzes PGE₂ production, and so we used a previously published mPGES morpholino to block its expression [19] (Figure S2). Unfortunately, mPGES-mediated PGE₂ is required for cell movements during epiboly [19]. To bypass this problem, we rescued normal early development of mPGES morphants by incubating them in dmPGE₂. Then, after epiboly, we transferred half of the morphants into fresh medium without dmPGE₂ at 48 hr post-fertilization (hpf; Figure S3); V12RAS⁺ cell numbers were analyzed at 4.5 days post-fertilization (dpf). Again, we saw a reduction in the number of V12RAS⁺ cells in mPGES morphants compared with control-morpholino-injected larvae (Figures 1G, 1L, and 1M), but the number of V12RAS⁺ cells was partially restored in those mPGES morphants that continued with dmPGE₂ treatment (Figures 1G, 1L, and 1N).

In summary, both our pharmacological inhibition and genetic mPGES knockdown data suggest that PGE₂ plays an important role in promoting the growth of transformed cells. However, because ectopic dmPGE₂ failed to completely restore the growth of transformed cells to control levels in either our pharmacological-inhibition or genetic-knockdown experiments, it seems likely that there are also some PGE₂-independent influences on the growth of transformed cells.

PGE₂ Directly Promotes the Growth of Transformed Cells via the EP1 Receptor

To address whether PGE₂ exerts a direct effect on the growth of transformed cells, we next focused on which of the PGE₂ receptors was expressed by the transformed cells to mediate such a response. Our immunostaining data indicate that, of the
five PGE₂ receptors that exist in the zebrafish genome (ENSEMBL Zv9), only EP1 is highly expressed by the transformed cells (Figures 2A–2C) and has a particularly pronounced perinuclear localization, as previously reported for EP1 receptor localization in tissue cultured mammalian cells [20]. To test whether EP1 receptor was responsible for mediating the PGE₂ signal in transformed cells, we used two EP1-specific inhibitors, SC19220 and ONO-8711 (Cayman Chemicals), and both treatments led to a significant reduction in the number of V12RAS+ cells (reduced to 21.1%) (Figures 3D and 3E). These data suggest that immune cell trophic support is mediated through the PGE₂-EP1 receptor pathway, which acts directly on the transformed cells.

**An Ectopic Supplement of dmPGE₂ Can Partially Restore V12RAS⁺ Cell Growth in Leukocyte-Depleted Larvae**

Our data herein suggest that PGE₂ is produced by leukocytes as trophic support for the growth of transformed cells. If this is indeed the case, then we should be able to restore tumor growth in leukocyte-depleted larvae by adding dmPGE₂. We thus blocked leukocyte development by using a combined morpholino pu.1+gcsfr double knockdown, which effectively arrests all myeloid lineage development in zebrafish larvae until at least 4 dpf [21]. Leukocyte depletion does not affect general embryo development (Figure S4A–S4G); however, this absence of leukocytes led to a dramatic reduction in the number of V12RAS⁺ cells (Figures 3B and 3J). When we supplied dmPGE₂ to the leukocyte-depleted double morphants, we saw a partial restoration of V12RAS⁺ cell numbers (Figures 3C and 3J). These data suggest that immune cell trophic support is recruitment of several innate immune cell lineages [14]. We now wished to dissect the contribution of individual leukocyte lineages to the growth of transformed cells. In zebrafish, neutrophil development is severely impaired in gcsfr-morpholino-injected larvae, whereas macrophage numbers are only slightly decreased [21] (Figure S4K). In such neutrophil-depleted morphants, we observed that V12RAS⁺ cell numbers are reduced almost to the numbers seen in pu.1+gcsfr morphants (which lack both neutrophils and macrophages; Figures 3B and 3D; Figure S4I). This suggests an important trophic role for neutrophils during the initial expansion of transformed cells.

IRF8 is a transcription factor that regulates the differentiation of a common progenitor into macrophages rather than neutrophils, and _irf8_ morpholino treatment depletes macrophages and results in a compensatory increase in neutrophils [22] (see Figure S4J). In these macrophage-depleted larvae, we again saw a reduction in the number of V12RAS⁺ cells (reduced to 41.9%) but to a much lesser degree than in total leukocyte (pu.1+gcsfr morphant, macrophage + neutrophil)-depleted larvae (reduced to 21.1%) (Figures 3B, 3F, and 3J). We confirmed that macrophage depletion alone (i.e., without a compensatory increase in neutrophils) also leads to a reduction in the number of V12RAS⁺ cells number (reduced to 49%) by using low-dose _pu.1_ morpholino (Figures 3H and 3L). These data suggest that macrophages contribute to the trophic support of transformed cells but to a lesser extent than neutrophils.

Moreover, the nature of trophic support received from neutrophils could be qualitatively different from that received from macrophages. When dmPGE₂ was used to treat larvae
that had been depleted of different immune cell types, we saw differences in the rescue profile of transformed-cell growth. In both pu.1+gcsfr double morphants (lacking both macrophages and neutrophils) and gcsfr morphants (lacking only neutrophils), dmPGE₂ only partially restored V12RAS⁺ cell numbers (Figures 3C, 3E, 3J, and 3K). However, in macrophage-depleted irf8 morphants and low-dose pu.1 morphants, dmPGE₂ treatment completely restored the number of transformed cells (Figures 3G, 3I, 3L, and 3M). It has previously been shown that PGE₂ can drive hematopoietic stem cell expansion [23], and so we tested whether leukocyte rescue by dmPGE₂ treatment might indirectly cause increased numbers of transformed cells, but we saw no significant recovery of depleted innate immune cells in these larvae (Figures S4I–S4N). These findings suggest that macrophages contribute PGE₂ alone, whereas neutrophils might produce other trophic factor(s).

Reduced PGE₂ Production Leads to Altered Neutrophil Migration in the Vicinity of Transformed Cells, and Increased Cell Death of Transformed Cells Follows along with Their Rapid Engagement by Macrophages

It has been shown that PGE₂ regulates immune cell function, and several recent reports suggest that PGE₂ might induce an immunosuppressive phenotype in leukocytes [24–26]. We wondered whether suppressing PGE₂ production with COX-2 inhibitors might modulate the early inflammatory response and change the way in which leukocytes and transformed cells interact.

Cell-tracking analysis of time-lapse movies show that in COX-2 inhibitor (NS398)-treated larvae, neutrophils near clones of transformed cells show considerably reduced motility (migration velocity drops from 0.125 ± 0.046 μm to 0.054 ± 0.038 μm, [mean ± SD]) (Figures 4A, 4A', 4B, 4B', and 4C; also see Movie S1) in comparison to those in untreated
transformed-cell-bearing larvae, indicating that reduced PGE\(_2\) does indeed lead to a change in neutrophil behavior.

Live-imaging studies by us and others have defined the “inflammatory macrophage” in zebrafish larvae by their typical elongated, dendritic morphology and slow patrolling behavior [14, 27]. Here we used Tg(NF\(_k\)B-RE:eGFP; LysC:DsRed; kit\(_a\):GalTA4;UAS:eGFPV12RAS) larvae, in which macrophages are labeled with low levels of NF\(_k\)b reporter GFP (Figure 4D; also see Movie S2) to reveal their behavior near clones of transformed cells. In untreated larvae, transformed-cell deaths are sufficiently rare that we have never captured them by live imaging in either the presence or the absence of immune cells [14]. By contrast, in larvae treated with COX-2 inhibitor (NS398), we frequently saw transformed-cell deaths, and often these were associated with prior macrophage encounters (Figure 4D; see also Movie S2). The corpses of transformed cells were subsequently rapidly cleared away by adjacent macrophages. These data suggest that reduction of PGE\(_2\) levels by COX-2 inhibition leads to a change of macrophage behavior and enhanced proinflammatory activity, which results in a more active engagement and engulfment of transformed cells. This is consistent with recent reports that PGE\(_2\) directs macrophages toward a tumor-promoting M2 phenotype [24, 28] and can redirect dendritic cells toward a stable myeloid-derived-suppressor-cell phenotype [25].

Our previous and current studies reveal a pivotal contribution of host immune cells to the optimal growth of transformed cells as they first arise in tissues [14]. Here we show that leukocyte-derived PGE\(_2\) is a key trophic factor for transformed cells at these early stages of cancer initiation. Our data suggest that PGE\(_2\) might work in two complementary ways, both directly on transformed cells via the EP1 receptor and indirectly by promoting a “trophic inflammatory cell” behavior in neutrophils and macrophages; this behavior might also support the survival of transformed cells by inhibiting killing and engulfment.

We have provided evidence here that a trophic inflammatory response is important for a transformed cell to grow at its inception and that PGE\(_2\) produced by innate immune cells via the COX-2 pathway is a key trophic factor for optimal growth of transformed cells at the earliest stages of tumor progression. Moreover, this trophic inflammatory response can be suppressed by the inhibition of PGE\(_2\) production via COX-2 inhibitors, which might explain why use of non-steroidal anti-inflammatory drugs (NSAIDs) can reduce cancer incidence.

Experimental Procedures

Zebrafish Strains and Maintenance

Adult zebrafish (Danio rerio) were maintained as previously described [29]. All experiments were conducted with local ethical approval from the University of Bristol and in accordance with UK Home Office regulations. Strains included Tg(SXUAS:eGFP-H-RASV12)io6 [30], Et(kit a:GalTA4,UAS:mCherry);hzm1 [30], Tg(LysC:DsRed); Et(kit a:GalTA4,UAS:mCherry);hzm1 [31]; the Tg(NF\(_k\)B-RE:eGFP)i235 line was generated with the method and constructs described in Kanther et al. [32].
Morpholino Injection
All morpholinos were obtained from (GeneTools LLC, Philomath, OR, USA) and injected into one-cell-stage embryos as previously described [19, 21, 22, 33]. For sequence information, see Supplemental Experimental Procedures.

Immunofluorescence, Live Imaging, and Tracking of Cell Movements in Larvae
Whole-mount immunostaining was performed as previously described [14]. For all our live-imaging studies, time-lapse movies were collected with a Leica SP5-AOBS Confocal Laser-Scanning Microscope. An Image J 1.4, Manual Tracking plugin was used for cell tracking (further details are available in the Supplemental Experimental Procedures).

Pharmacological Treatment and Clonal Analysis of the Progression of Transformed Cells
Transformed-cell-bearing larvae were treated with inhibitors of PGE\(_2\)-synthesis enzymes or dmPGE\(_2\) from 48 hpf to 88 hpf or from 48 hpf to 96 hpf in 0.3% Danieau’s solution containing 1% DMSO. All the inhibitors were from Cayman Chemicals. For detailed procedures, see Supplemental Experimental Procedures.

Statistics
All the data were analyzed (Prism 4.1, GraphPad Software, La Jolla, CA, USA) with an unpaired two-tailed Student’s t test for comparisons between two groups with a one-way ANOVA and appropriate post-test adjustment for comparisons of multiple groups.

Supplemental Information
Supplemental Information includes four figures, two movies, and Supplemental Experimental Procedures and can be found with this article online at doi:10.1016/j.cub.2012.05.010.

Acknowledgments
We thank Chris Paraskeva and Helena Smartt for useful discussions during the preparation of our manuscript and Nikolay Ogryzko for generation of the N\(\text{F}_{1}\)B line; this study was funded by a Wellcome Trust program grant to P.M.
