Abstract. Cardiomyocyte apoptosis is a major event in the pathogenesis of diabetic cardiomyopathy. Currently, no single effective treatment for diabetic cardiomyopathy exists. The present study investigated whether advanced oxidative protein products (AOPPs) have a detrimental role in the survival of cardiomyocytes and if glucagon-like peptide-1 (GLP-1) exerts a cardioprotective effect under these circumstances. The present study also aimed to determine the underlying mechanisms. H9c2 cells were exposed to increasing concentrations of AOPPs in the presence or absence of GLP-1, and the viability and apoptotic rate were detected using a cell counting kit-8 assay and flow cytometry, respectively. In addition, a phosphatidylinositol-4,5-bisphosphate 3-kinase (PI3K) inhibitor, LY294002, was employed to illustrate the mechanism of the antiapoptotic effect of GLP-1. The expression levels of the apoptotic-associated proteins, Akt, B-cell lymphoma (Bcl)-2, Bcl-2-associated death promoter (Bad), Bcl-2-associated X protein (Bax) and caspase-3 were measured by western blotting. It was revealed that GLP-1 significantly attenuated AOPP-induced cell toxicity and apoptosis. AOPPs inactivated the phosphorylation of Akt, reduced the phosphorylation of Bad, decreased the expression of Bcl-2, increased the expression of Bax and the activation of caspase-3 in H9c2 cells. GLP-1 reversed the above changes induced by AOPPs and the protective effects of GLP-1 were abolished by the PI3K inhibitor, LY294002. In conclusion, the present data suggested that GLP-1 protected cardiomyocytes against AOPP-induced apoptosis, predominantly via the PI3K/Akt/Bad pathway. These results provided a conceivable mechanism for the development of diabetic cardiomyopathy and rendered a novel application of GLP-1 exerting favorable cardiac effects for the treatment of diabetic cardiomyopathy.

Introduction

The incidence and prevalence of diabetes mellitus (DM) are increasing globally (1). Cardiovascular complications are the leading causes of morbidity and mortality in patients with diabetes. Among them, diabetic cardiomyopathy (DCM) is defined as a distinct primary disease process, independent of coronary artery disease, hypertension or any other cardiovascular diseases, which leads to ventricular dysfunction and heart failure (2). However, the pathogenesis of DCM remains to be elucidated. To date, certain cellular and molecular defects are believed to be responsible for the pathogenesis of DCM, including glucotoxicity, altered lipid metabolism, lipotoxicity, oxidative stress, abnormal calcium handling, protein kinase C signaling, apoptosis/inflammation/fibrosis and mitochondrial dysfunction (3). In particular, growing evidence has demonstrated that apoptosis of cardiomyocytes is vital in the development of DCM (4,5). Therefore, inhibition of cardiac apoptosis is of great importance in the prevention and treatment of DCM (6).

Advanced oxidative protein products (AOPPs) are the dityrosine-containing and cross-linking protein products, which are formed during oxidative stress by the reaction between proteins and chlorinated oxidants (7). AOPPs were initially discovered in the plasma of patients with uremia and undergoing dialysis, and are considered as a novel marker of oxidative stress. Increased levels of plasma AOPPs were demonstrated in patients with DM, coronary artery disease and metabolic syndrome (8-10). In addition, AOPPs were significantly higher in the diabetic group with vascular complications compared with the group without complications (11). In vitro, incubation of AOPPs with human umbilical vein endothelial cells induced superoxide generation, activated NAD(P)H oxidase, extracellular-signal regulated kinase (ERK)1/2 and p38, and...
promoted nuclear translocation of NF-κB, by bonding to the receptor for advanced glycation end products (RAGEs) (12). In experimental models, accumulation of AOPPs activated the p53/Bax/caspase-dependent proapoptotic pathway via RAGE and resulted in podocyte apoptosis (13). However, the exact role of AOPPs in the myocardial cells of DCM remains to be elucidated.

Glucagon-like peptide-1 (GLP-1) is a multifunctional hormone secreted from intestinal endocrine L cells and is widely used for the treatment of diabetes. As well as its effects on glucose control, GLP-1 reduces gastric emptying, inhibits appetite and exhibits a protective effect on cardiovascular diseases (14,15). The GLP-1 receptor (GLP-1R) was identified in the heart and vascular tissue, in addition to pancreatic α and β cells (16,17). A previous study demonstrated that the GLP-1R agonist, liraglutide, inhibits endothelial cell dysfunction and alleviates atherosclerotic injury (14). In rats with chronic heart failure, subcutaneous infusion with GLP-1 and its analogues, exenatide, improves cardiac function, cardiac remodeling and survival (18). Furthermore, GLP-1 directly protects cardiomyocytes from hypoxia/reoxygenation injury, predominantly by inhibiting their apoptosis (19) and protects vascular endothelial cells against AGE-induced apoptosis (20). However, whether GLP-1 has a protective effect on AOPP-treated cardiomyocytes remains to be elucidated.

Therefore, the present study aimed to investigate whether AOPPs have a detrimental role in the survival of cardiomyocytes and if GLP-1 exerts cardioprotective effects under certain circumstances. The present study focussed on the effect of GLP-1 on the apoptosis of H9c2 myocardial cells induced by AOPPs and its underlying mechanism. It was demonstrated that GLP-1 alleviates AOPP-induced apoptosis via the PI3K/Akt/Bad pathway in H9c2 cells. In conclusion, these data presented a theoretical foundation and novel insight into the pathogenic and therapeutic strategy of DCM.

Materials and methods

Materials. Dulbecco's modified Eagle's medium (high glucose) and phosphate-buffered saline (PBS) were purchased from Hyclone (Logan, UT, USA). Fetal bovine serum (FBS), penicillin-streptomycin solution and 0.25% Trypsin-EDTA were purchased from (Thermo Fisher Scientific, Inc., Waltham, MA, USA). Dimethyl sulfoxide, diethyl pyrocarbonate, rat serum albumin (RSA), bovine serum albumin (BSA), paraformaldehyde, Triton X-100, 4',6-diamidino-2-phenylindole (DAPI), GLP-1 (7-36 amide) and the amebocyte lysate assay kit were all purchased from Sigma-Aldrich (St Louis, MO, USA). The following antibodies were purchased from Cell Signaling Technologies (Boston, MA, USA): Rabbit monoclonal phosphorylated (p)-Akt (Ser473; cat. no. CST4060P), rabbit monoclonal anti-Akt (cat. no. CST4695), rabbit anti-B-cell lymphoma (Bel)-2 (cat. no. CST2876) rabbit monoclonal p-Bcl-2-associated death promoter (Bad; Ser136; cat. no. CST4366P), rabbit anti-Bcl-2-associated X protein (Bax; cat. no. CST2772) and rabbit anti-caspase-3 (cat. no. CST9662). Mouse anti-RAGE antibody (cat. no. SC33662) was provided by Santa Cruz Biotechnology, Inc. (Heidelberg, Germany). Rabbit anti-GLP1R antibody (cat. no. ab39072) was purchased from Abcam (Cambridge, MA, USA). A Cell Counting kit (CCK)-8 was purchased from Dojing Laboratories (Kumamoto, Japan). LY294002 and a Hoechst 33258 Staining kit were purchased from Beyotime Institute of Biotechnology (Haimen, China). RNAiso plus, SYBR Premix EX Taq II kit and PrimeScript™ RT reagent kit were purchased from Takara Biotechnology Co., Ltd. (Dalian, China). Hypochlorous acid (HOCl) was purchased from Fluke (Buchs, Switzerland). An annexin V-fluorescein isothiocyanate (FITC) apoptosis detection kit was purchased from eBioscience (San Diego, CA, USA). A bicinchoninic assay protein assay kit was purchased from Keygen Biotech Co., Ltd. (Nanjing, China). Rabbit anti-GAPDH antibody, anti-rabbit or anti-mouse horseradish peroxidase-conjugated secondary immunoglobulin (Ig)G were obtained from Wuhan Boster Biological Technology, Ltd. (Wuhan, China). FITC-labeled anti-mouse IgG and anti-rabbit IgG were purchased from EarthOx, LLC (San Francisco, CA, USA).

Cell culture. The H9c2 (2-1) cells (21) were a generous gift from the Department of Cardiology, Nanfang Hospital (Guangzhou, China). The H9c2 cells were cultured in Dulbecco's modified Eagle's medium (high glucose), containing 10% FBS and 1% penicillin-streptomycin solution in a 5% carbon dioxide atmosphere at 37°C. The cells were subcultured every 2-3 days at a ratio of 1:2 or 1:3.

AOPPs preparation and determination. AOPPs-RSA was prepared in vitro, as previously described (7,13). Briefly, 20 mg/ml RSA solution was mixed and placed with 40 mmol/l HOCl in PBS for 30 min at 37°C. The prepared samples were dialyzed against PBS for 24 h to remove free HOCl and passed through a Detoxi-Gel column (Pierce, Rockford, IL, USA) to remove contaminated endotoxin. A total of 20 mg/ml RSA solution was mixed with isometric PBS as a comparison. The content of AOPPs in the AOPPs-RSA and unmodified RSA were 70.7 and 0.11 nmol/mg protein, respectively. Endotoxin levels in the AOPPs-RSA and unmodified RSA were measured with the amebocyte lysate assay kit and were determined to be >0.25 EU/ml.

Cell viability. The H9c2 cells were seeded into 96-well plates at a density of 2.5x10^3 and were treated with the indicated concentrations of AOPPs-RSA and GLP-1. Following incubation for 24 h, the medium was replaced with 10% CCK-8 solution for 2 h at 37°C. The absorbance was measured at 450 nm with a microplate reader (EXL808; BioTek, Winooski, VT, USA), according to the manufacturer's instructions.

Cell apoptosis. Each group of cells were detected by double staining with FITC-conjugated annexin V and propidium iodide (PI). The collected cells were washed twice with PBS and stained with 5 μl annexin V-FITC for 15 min in the dark in binding buffer (eBioscience, San Diego, CA, USA). Subsequently, 10 μl PI was added at room temperature for 5 mins. Cell apoptosis was determined using a FACSVersus flow cytometer (BD Biosciences, San Jose, CA, USA) using the FACSuite program (BD Biosciences).
and stained with 10 µg/ml Hoechst 33258 for 5 min at room temperature. The morphological changes were observed under a fluorescence microscope (Axio Scope A1; Carl Zeiss, Jena, Germany) at a wavelength of 350 nm.

**Immunofluorescence assay.** Following treatment, the cells were fixed in 4% paraformaldehyde for 15 min and permeabilized with Triton X-100 for 15 min at room temperature. Following washing the cells twice with PBS, the cells were blocked in 1% BSA for 30 min at room temperature. The cells were subsequently incubated overnight at 4°C with primary antibody (RAGE, 1:100; GLP-1, 1:100) in 1% BSA. Following washing twice with PBS, the cells were incubated with FITC-labeled anti-mouse or anti-rabbit IgG secondary antibodies (1:200) for 1 h at room temperature. Finally, the cells were stained with 100 ng/ml DAPI for 2 min at room temperature and immunofluorescent images were captured using a fluorescence microscope (Axio Scope A1; Carl Zeiss).

**Western blot analysis.** Following treatment, the cellular proteins were extracted using radioimmunoprecipitation lysis buffer (Sangon Biotech Co., Ltd., Shanghai, China) for 30 min at 4°C and centrifuged at 250 × g for 20 min at 4°C. The protein concentration was measured using a bicinchoninic assay kit on an EXL808 microplate reader. The proteins (50 µg) were separated on 12% SDS-polyacrylamide gels (Whiga, Guangdong, China) and were transferred onto polyvinylidene fluoride membranes (Bio-Rad Laboratories, Hercules, CA, USA). The membranes were blocked in 5% non-fat milk in Tris-buffered saline, containing 0.1% Tween-20 (TBST), for 2 h at room temperature and were subsequently immunoblotted with primary antibodies for 2 h at room temperature. Antibodies against p-Akt (1:2,000), Akt (1:1,000) p-Bad (1:1,000), Bax (1:1,000), Bel-2 (1:1,000), caspase-3 (1:1,000), RAGE (1:100) and GLP-1R (1:1,000) were used. Following washing three times with TBST, the membranes were incubated with anti-rabbit or anti-mouse hors eradish peroxidase-conjugated secondary IgG (1:2,500) at room temperature for 1 h. The protein bands were visualized using an enhanced chemiluminescence kit (EMD Millipore, Billerica, MA, USA).

**Reverse transcription-quantitative polymerase chain reaction (RT-qPCR).** The total RNA was extracted using RNAiso Plus, according to the manufacturer's instructions. The purity of each RNA sample was measured using a Nanodrop 2000 spectrophotometer (Thermo Fisher Scientific, Inc.). To remove genomic DNA contamination, the RNA samples were treated with gDNA Eraser (Takara Biotechnology Co., Ltd.) at 42°C for 15 min, with a peak at 50 nmol/l (97.9%; Fig. 1B). Therefore, subsequent experiments were performed using 1 µg/ml AOPPS-RSA and 50 nmol/l GLP-1. These results demonstrated that GLP-1 protects AOPPs-RSA-induced toxicity in H9c2 cells.

**GLP-1 attenuates AOPP-induced toxicity in H9c2 cells.** To confirm if AOPPs are toxic on cell viability, a CCK-8 assay was performed in AOPP-treated H9c2 cells. As shown in Fig. 1A, incubation with AOPPs-RSA for 24 h significantly inhibited cell viability (84.2 to 64.5%) in a dose-dependent manner (r=–0.797, P<0.000) while RSA caused no effect. In addition, H9c2 cells were incubated with 1 µg/ml AOPPS-RSA for 24 h in the presence or absence of different concentrations of GLP-1. Compared with AOPP-RSA, GLP-1 partly restored cell viability in a dose-dependent manner (r=0.698, P=0.004), with a peak at 50 nmol/l (97.9%; Fig. 1B). Therefore, subsequent experiments were performed using 1 µg/ml AOPPS-RSA and 50 nmol/l GLP-1. GLP-1 attenuates AOPP-RSA-induced toxicity in H9c2 cells.

**GLP-1 attenuates AOPP-induced apoptosis in H9c2 cells.** The proapoptotic effect of AOPPs on H9c2 cells was assessed. The morphological changes were detected by staining cells with Hoechst 33258 (Fig. 1C). An increase in the number of apoptotic cells was observed in the AOPP-treated cells and a decrease in the AOPP- and GLP-1-treated cells. Following co-incubation with LY294002, the number of apoptotic cells increased. As shown in Fig. 1D, cells incubated with AOPPS-RSA exhibited a significant increase in the apoptotic rate (15.8%) compared with the control group (1.3%; P<0.01). This increment was blunted in the presence of GLP-1 (9.7%, P<0.01, vs. the AOPPs group). The PI3K inhibitor, LY294002, was used to determine the mechanisms behind the antiapoptotic effects of GLP-1.

**Statistical analysis.** All data are expressed as the mean ± standard deviation. Differences between groups were assessed by one-way or Welch analysis of variances (equal variances not assumed) once normality was confirmed. For pairwise comparison, a least significant difference test or Dunnett's T3 test was used when the equal variances were not assumed. Spearman's rank correlation was used for correlation analysis. P<0.05 was considered to indicate a statistically significant difference. All analyses were performed with SPSS 13.0 software (SPSS Inc., Chicago, IL, USA).

**Results**

**GLP-1 attenuated AOPP-induced toxicity in H9c2 cells.** To determine the expression of RAGE was upregulated by exposure to AOPP-RSA in a dose-dependent manner (Fig. 2A) in H9c2 cells. In addition, GLP-1 (50 nM for 24 h) significantly downregulated the protein and mRNA expression levels of RAGE (Fig. 2B and C). Therefore, GLP-1 may protect
ZHANG et al: GLP-1 PROTECTS CARDIOMYOCYTES FROM APOPTOSIS VIA PI3K/Akt/BAD SIGNALING

GLP-1 exerts its protective function via the GLP-1R in H9c2 cells. The presence of the GLP-1R has been identified in different cells and the interaction of GLP-1 with the GLP-1R has been determined to be responsible for multiple function of GLP-1 (23). Therefore, the present study confirmed that H9c2 cells express the GLP-1R (Fig. 3A). In addition, the mRNA and protein expression levels of GLP-1R were upregulated by exposure to GLP-1 itself (Fig. 3B and C). Therefore, it was speculated that GLP-1 may exert its protective function via the GLP-1R in H9c2 cells.

GLP-1 prevents AOPP-induced apoptosis via the PI3K/Akt/Bad pathway in H9c2 cells. The role of the PI3K/Akt/Bad pathway and GLP-1 in preventing AOPP-induced apoptosis in H9c2 cells was investigated. Firstly, AOPP-RSA significantly inactivated Akt phosphorylation at Ser473 (Fig. 4A) and subsequently reduced Bad phosphorylation at Ser136 (Fig. 4B) compared with the control and RSA group. In addition, a decrease of the anti-apoptotic protein, Bcl-2 (Fig. 4C), and an increase of the proapoptotic protein, Bax (Fig. 4D), was demonstrated in AOPPs-RSA treated cells. In addition, the elevated expression of caspase-3 was demonstrated by western blotting (Fig. 4E). However, these changes were reversed in the presence of GLP-1 (Fig. 4). Furthermore, the effect of GLP-1 was abrogated following treatment of the H9c2 cells with a PI3K inhibitor, LY294002 (Fig. 4). These results indicated that GLP-1 prevented AOPP-induced apoptosis via the PI3K/Akt/Bad pathway in H9c2 cells.

Discussion

The major findings of the present study were as follows: i) AOPPs induced apoptosis in H9c2 cells; ii) GLP-1 prevented AOPP-induced apoptosis by downregulating the expression of RAGE.
AOPP-induced cell apoptosis; iii) GLP-1 exerted these cardioprotective effects predominantly via the PI3K/Akt/Bad pathway. This is the first study, to the best of our knowledge, to confirm that GLP-1 protected against AOPP-induced apoptosis in H9c2 cells.

AOPPs, as novel markers of oxidative stress, have been explored in several cell types. Previous studies have investigated the proapoptotic effect of AOPPs on vascular endothelial cells (12), podocytes (13), intestine epithelial cells (24) and rat osteoblast-like cells (25). However, previous studies, which focus on the effect of AOPPs in cardiomyocytes are rare. Valente et al (26) demonstrated that AOPPs induce neonatal and adult mouse cardiomyocyte death via Nox2/Rac1/superoxide-dependent TRAF3IP2/JNK signaling. In the present study, it was revealed that AOPP-treatment significantly increased the apoptotic rate of a rat ventricular myoblast cell line, H9c2. In addition, AOPPs decreased the phosphorylation of Akt and subsequently reduced the phosphorylation of Bad.

GLP-1 has been widely investigated in recent years. Numerous studies have confirmed that GLP-1 has anti-apoptotic functions in different types of cell, including pancreatic β cells (32), cholangiocytes (33), neurons (34) and cardiomyocytes (35). Consistent with previous reports, the present study proposed that GLP-1 protected against AOPP-induced apoptosis through the PI3K/Akt/Bad pathway.

Figure 2. GLP-1 downregulates the expression of RAGE in H9c2 cells. (A) H9c2 cells were immunostained with anti-mouse RAGE primary antibody and fluorescein isothiocyanate-conjugated secondary antibody (green), and were counterstained with DAPI (blue). The expression of RAGE was upregulated by exposure of increasing concentrations of AOPPs-RSA for 24 h (magnification, x400). (B) GLP-1 significantly decreased the protein expression of RAGE, as determined by western blotting. (C) GLP-1 significantly decreased the mRNA expression of RAGE as determined by reverse transcription-quantitative polymerase chain reaction. The data are expressed as the mean ± standard deviation of three independent experiments (*P<0.01, vs. control; **P<0.01, vs. AOPPs-RSA-treated cells). GLP-1, Glucagon-like peptide-1; AOPPs, advanced oxidation protein products; RSA, rat serum albumin; RAGE, receptor for advanced glycation end product; DAPI, 4',6-diamidino-2-phenylindole.
indicated that GLP-1 (7-36) inhibits AOPP-induced toxicity and apoptosis in H9c2 cells. The present study next investigated the mechanisms of this antiapoptotic effect of GLP-1.

Cytoprotective actions of GLP-1 have been substantiated in the heart. Notably, GLP-1 directly interacts with the myocardium due to the presence of the receptor of the GLP-1R (36,37). The present results demonstrated that the GLP-1R was expressed in H9c2 cells. Therefore, it is possible that GLP-1 can exhibit protective effect on H9c2 cells. AOPPs and AGEs are similar in structure and biological activity. AOPPs are demonstrated to induce cardiomyocyte death by interacting with a member of the immunoglobulin superfamily of cell surface molecules, RAGE (26). In the present study, it was confirmed that the expression of RAGE occurred in H9c2 cells and was upregulated following exposure to increasing concentration of AOPPs-RSA. In addition, it was revealed that GLP-1 downregulated not only the mRNA expression of RAGE, but also the protein expression. These data may partly explain why GLP-1 can inhibit AOPP-induced apoptosis in H9c2 cells.

The mechanisms underlying the anti-apoptotic effect of GLP-1 on the heart have been investigated by in vivo and in vitro experiments. For instance, in murine HL-1 cardiomyocytes, GLP-1 prevents the exposure of phosphatidylserine, the increase of the Bax:Bcl-2 ratio, the activation of Bad, mitochondrial membrane depolarization, the release of cytochrome c, the activation of caspase-3 and DNA fragmentation, induced by staurosporine (35). GLP-1R agonist, exendin-4, attenuates high glucose-induced cardiomyocyte apoptosis in association with decreased endoplasmic reticulum stress and markers of enhanced SERCA2a activity (38). Furthermore, exenatide increased the expression levels of p-Akt and Bcl-2, decreased the activity of caspase-3, reduced infarct size, and prevented deterioration of systolic and diastolic cardiac function in a porcine model of myocardial ischemia/reperfusion (39). However, the mechanisms of GLP-1 on the AOPP-induced apoptosis remain to be elucidated. Therefore, the present study investigated the PI3K/Akt pathway as a candidate for the underlying mechanisms.

It has been reported that GLP-1 and its analogues inhibit cardiomyocyte apoptosis by regulating numerous apoptotic-associated pathways, including the PI3K (40), cAMP (23) and ERK1/2 pathways (41). The present study demonstrated that when treated with a PI3K inhibitor, LY294002, the apoptotic rate of GLP-1 and AOPPs co-treated cells was increased, indicating that GLP-1 requires activation of the PI3K pathway to prevent AOPP-induced apoptosis in H9c2 cells. PI3K is a type of cellular protein kinase, which is involved in cell survival, growth and proliferation. Activated PI3K subsequently phosphorylated its downstream Ser/Thr protein kinase, Akt, also known as protein kinase B. The activation of the Akt pathway provides cells with a survival signal, which allows them to withstand apoptotic stimuli (42). Numerous reports elucidated the important roles of activating the PI3K/Akt signaling pathway in competing cell apoptosis in the heart (43-45). Bad, a Bcl-2 family member, can combine with
antiapoptotic factor Bcl-2 or Bcl-xL to form a proapoptotic complex. However, when Bad is phosphorylated at Ser136 by Akt, it is released from the proapoptotic complex and forms a complex with 14-3-3 proteins in the cytosol, therefore inactivating its proapoptotic function (46). Bad is hypothesized to be a downstream target of Akt in promoting cell survival (47).

The present data revealed that AOPP-treatment inactivated Akt and Bad phosphorylation, while GLP-1 restored this suppression. These effects of GLP-1 were correlated with the attenuation of cell apoptosis. However, LY294002 abolished these effects of GLP-1. Therefore, the antiapoptotic effects of GLP-1 were associated with, at least in part, activation of the PI3K/Akt/Bad pathway.

Apoptosis is the process of programmed cell death, which is regulated through the balance between proapoptotic and antiapoptotic proteins. The Bcl-2 family, as the key regulators of apoptosis, consists of both proapoptotic proteins, including Bax and Bad, and antiapoptotic members, including Bcl-2 and Bcl-xL. The proapoptotic protein Bax is necessary for mitochondrial outer membrane permeabilization, inducing cytochrome c release and leading to the activation of caspases (48). However, Bcl-2 inhibits this process by suppressing the translocation of Bax and therefore, reducing the activity of the caspases (49). Caspase-3 is a type of proteinase, which has a central role in the execution-phase of cell apoptosis only when it has been activated. Activation of caspase-3 requires proteolytic processing of its inactive zymogen into activated p17 and p12 fragments. Consistent with previous studies (35,50), the present study demonstrated that AOPPs decreased the expression of Bcl-2, and increased the expression of Bax and activation of caspase-3 in H9c2 cells. GLP-1 reversed these changes. Nevertheless, the effects of GLP-1 were partly abrogated by co-incubation with the PI3K inhibitor, LY294002. These findings suggested that the
mechanism by which GLP-1 protects H9c2 cells against the apoptotic effects of AOPPs is by shifting the balance between proapoptotic and antiapoptotic proteins via the PI3K/Akt/Bad pathway.

The prominent finding of the present study was that GLP-1 protected cardiomyocytes against AOPP-induced apoptosis. The possible mechanism may be associated with the PI3K/Akt/Bad survival pathway. Currently, no single effective treatment exists for DCM. The present findings provided a conceivable mechanism of the development of DCM and rendered a novel application of GLP-1 exerting favorable cardiac effects for the treatment of DCM.
