ON HOMOLOGY OF LINEAR GROUPS OVER $k[t]$

MATTHIAS WENDT

Abstract. This note explains how to prove that for any simply-connected reductive group $G$ and any infinite field $k$, the inclusion $k \hookrightarrow k[t]$ induces an isomorphism on group homology. This generalizes results of Soulé and Knudson. The result can be used to deduce the degree 3 case of the Friedlander-Milnor conjecture for simply-connected Chevalley groups of rank at least 2, using Morel’s $A^1$-homotopy approach.

1. Introduction

The question of homotopy invariance of group homology is the question under which conditions on a linear algebraic group $G$ and a commutative ring $R$ the natural morphism $G(R) \to G(R[t])$ induces isomorphisms in group homology. This is an unstable version of homotopy invariance for algebraic K-theory as established by Quillen in [Qui73].

The two main results which have been obtained in this direction are due to Soulé and Knudson. In [Sou79], Soulé determined a fundamental domain for the action of $G(k[t])$ on the associated Bruhat-Tits building and deduced homotopy invariance for fields of characteristic $p > 0$ with field coefficients prime to $p$. In [Knu97], Knudson extended Soulé’s approach and deduced homotopy invariance with integral coefficients for $SL_n$ over infinite fields.

In this paper, we generalize Knudson’s theorem to arbitrary reductive groups, cf. Theorem 4.4:

Theorem 1.1. Let $k$ be an infinite field and let $G$ be a reductive smooth linear algebraic group over $k$. Then the canonical inclusion $k \hookrightarrow k[t]$ induces isomorphisms

$$H_\bullet(G(k), \mathbb{Z}) \xrightarrow{\cong} H_\bullet(G(k[t]), \mathbb{Z}),$$

if the order of the fundamental group of $G$ is invertible in $k$.
It follows from the work of Krsti´c and McCool [KM97] that homotopy invariance does not work for \( H_1 \) of rank one groups over integral domains which are not fields. In the case of rank two groups, homotopy invariance fails for \( H_2 \) as discussed in [Wen12]. It therefore seems that one cannot hope for an extension of the above result for arbitrary regular rings or even polynomial rings in more than 1 variable.

Nevertheless, even the one-variable case is already interesting enough. Morel has recently used \( \mathbb{A}^1 \)-homotopy theory to prove a weak version of the Friedlander-Milnor conjecture for the simplicial resolution \( G(k[\Delta^\bullet]) \) of a semisimple algebraic group \( G \), cf. [Mor12]. He also announced a weak version of homotopy invariance \( H_\bullet(G(k), \mathbb{Z}) \cong H_\bullet(G(k[\Delta^\bullet]), \mathbb{Z}) \) which would then prove the Friedlander-Milnor conjecture. The one-variable case of homotopy invariance [Theorem 1.1] together with homotopy invariance for \( H_1 \) of Chevalley groups of rank \( \geq 2 \) allows to give a different proof of the above weak homotopy invariance for homological degrees \( \leq 3 \).

By the results of [Mor12], this has the following consequence, cf. Corollary 5.4:

**Corollary 1.2.** Let \( K \) be an algebraically closed field, let \( G \) be a simply-connected Chevalley group of rank at least 2 and let \( \ell \) be a prime with \( (\ell, \text{char } K) = 1 \). Then the natural homomorphism

\[
H^3_{\text{et}}(BG_K, \mathbb{Z}/\ell\mathbb{Z}) \to H^3(BG(K), \mathbb{Z}/\ell\mathbb{Z})
\]

is an isomorphism.

**Structure of the paper:** In Section 2, we reduce to simply-connected absolutely almost simple groups. Section 3 recalls the necessary facts on Bruhat-Tits theory and Margaux’s generalization of Soulé’s theorem. In Section 4 we extend the homology computations of Knudson to groups other than \( \text{SL}_n \). Finally, in Section 5, we discuss the degree 3 case of the Friedlander-Milnor conjecture.

**Acknowledgements:** I have to apologize for the numerous gaps in previous versions of this work. I would like to thank Mike Hopkins for pointing out a critical error in an earlier version, and Christian Haesemeyer and Aravind Asok for pointing out problems with Knudson’s injectivity argument in the rank two case. I also thank Aravind Asok, Christian Haesemeyer, Roy Joshua and Fabien Morel for many useful comments and their interest in the homotopy invariance question.

## 2. Preliminary reduction

In this section, we provide some preliminary reductions. More precisely, [Theorem 1.1] follows for all reductive groups if it can be shown for simply-connected almost simple groups. The arguments are fairly standard reductions, ubiquitous in the theory of algebraic groups.

Recall from [Bor91] the basic notions of the theory of linear algebraic groups. In particular, the **radical** \( R(G) \) of a group \( G \) is the largest connected solvable normal subgroup of \( G \), and the **unipotent radical** \( R_u(G) \) of \( G \) is the largest connected unipotent normal subgroup of \( G \). A group \( G \) is called **reductive** if its unipotent radical is trivial, and it is called **semisimple** if its radical is trivial. A connected algebraic group \( G \) is called **simple** if it is non-commutative and has no nontrivial normal algebraic subgroups. It is called **almost simple** if its centre \( Z \) is finite and the quotient \( G/Z \) is simple. A semisimple group is called **simply-connected**, if there is no nontrivial isogeny \( \phi : \tilde{G} \to G \).

The additive group is denoted by \( \mathbb{G}_a \), and the multiplicative group by \( \mathbb{G}_m \). A **torus** is a linear algebraic group \( T \) defined over a field \( k \) which over the algebraic closure \( \overline{k} \) is isomorphic to \( \mathbb{G}_m^n \) for some \( n \).

We now show that the main theorem follows for reductive groups if it can be proved for almost simple simply-connected groups. We first reduce to semisimple
groups, the basic idea to keep in mind is the sequence $SL_n \to GL_n \to G_n$ which reduces homotopy invariance for $GL_n$ to $SL_n$.

**Proposition 2.1.** To prove Theorem 1.1, it suffices to consider the case where $G$ is semisimple over $k$.

*Proof.* For a reductive group $G$, we have a split extension of linear algebraic groups

$$1 \to (G, G) \to G \to G/(G, G) \to 1$$

where $(G, G)$ denotes the commutator subgroup in the sense of linear algebraic groups. The quotient $G/(G, G)$ is a torus. We denote $H = (G, G)$ and $T = G/(G, G)$, and obtain a split exact sequence $1 \to H(A) \to G(A) \to T(A) \to 1$ for any $k$-algebra $A$. Assuming that $A$ is smooth and essentially of finite type, we have an isomorphism $T(A) \cong T(A[t])$. From the Hochschild-Serre spectral sequence for the above group extensions we conclude that $G(k) \to G(k[t])$ induces an isomorphism on homology if $H(k) \to H(k[t])$ induces an isomorphism on homology. But $H = (G, G)$ is a semisimple algebraic group over $k$. □

**Proposition 2.2.** To prove Theorem 1.1, it suffices to consider the case where $G$ is almost simple simply-connected over $k$.

*Proof.* For a semisimple group $G$, there is an exact sequence of algebraic groups

$$1 \to \Pi \to \tilde{G} \to G \to 1,$$

where $\Pi$ is a finite central group scheme, and $\tilde{G}$ is a product of simply-connected almost simple groups. If we assume that Theorem 1.1 holds for these simply-connected almost simple groups, it is also true for their product, by a simple application of the Hochschild-Serre spectral sequence.

Now assume that the order of $\Pi$ is prime to the characteristic of the field $k$, as in Theorem 1.1. From the universal covering above we have an exact sequence

$$1 \to \Pi(R) \to \tilde{G}(R) \to G(R) \to H^1_{\text{ét}}(R, \Pi) \to H^1_{\text{ét}}(R, \tilde{G})$$

for any $k$-algebra $R$. Then we have isomorphisms

$$\Pi(k) \cong \Pi(k[t]), \quad \text{and} \quad H^1_{\text{ét}}(k, \Pi) \cong H^1_{\text{ét}}(k[t], \Pi),$$

by our assumption on the characteristic of the base field.

Now the first part of the exact sequence above yields a morphism of exact sequences

$$
\begin{array}{ccc}
1 & \to & \Pi(k) \\
\downarrow & & \downarrow \\
1 & \to & \Pi(k[t]) \\
\end{array}
\begin{array}{ccc}
\to & \tilde{G}(k) & \tilde{G}(k)/\Pi(k) \\
\to & \tilde{G}(k[t]) & \tilde{G}(k[t])/\Pi(k[t]) \\
\cong & & 1 \\
\end{array}
\begin{array}{ccc}
1 & \to & 1 \\
\end{array}
$$

Since $\Pi$ is in fact abelian, one can consider fibre sequences

$$B\tilde{G}(R) \to B\tilde{G}(R)/\Pi(R) \to K(\Pi(R), 2)$$

for $R = k$ and $R = k[t]$. Then the associated Hochschild-Serre spectral sequence implies that the morphism $\tilde{G}(k)/\Pi(k) \to \tilde{G}(k[t])/\Pi(k[t])$ induces an isomorphism on homology, since we argued before that the morphism $\tilde{G}(k) \to \tilde{G}(k[t])$ induces an isomorphism on homology.

Since

$$H^1_{\text{ét}}(k, \tilde{G}) \to H^1_{\text{ét}}(k[t], \tilde{G})$$

is injective ($k$ is a retract of $k[t]$), the images of $G(k[t])$ and $G(k)$ in $H^1_{\text{et}}(k, \Pi) \cong H^1_{\text{et}}(k[t], \Pi)$ are equal - we denote these images by $\pi_0(G(k[t]))$ and $\pi_0(G(k))$, respectively. Therefore we get a morphism of extensions.
The outer vertical arrows are isomorphisms on homology, therefore the comparison theorem for the Hochschild-Serre spectral sequences implies that we obtain an isomorphism on the middle arrow.

Henceforth, we shall only consider linear algebraic groups $G$, defined over $k$ which are almost simple and simply-connected.

3. Bruhat-Tits buildings and Soulé’s theorem

In this section, we recall the basics of the theory of buildings which will be needed in the remaining sections. The main references are [BT72] and [AB08].

Let $k$ be a field. Then we equip the function field $K = k(t)$ with the valuation $\omega_K(f/g) = \deg(g) - \deg(f)$, whose uniformizer is $t^{-1}$. We denote by $O$ the corresponding discrete valuation ring. Alternatively, one can work with $K = k((t^{-1}))$ and the corresponding valuation ring $k[[t^{-1}]]$. The underlying simplicial complex of the building will be the same, only the apartment system will be different.

Let $G$ be a reductive group over $k$. Then we have two morphisms of groups, the inclusion $G(O) \hookrightarrow G(K)$ and the reduction $G(O) \to G(k)$.

3.1. BN-Pairs and buildings. We will be concerned with affine buildings associated to reductive groups over discretely valued fields. We recall the definition of buildings based on the notion of BN-pairs. This theory is detailed in [AB08], in particular Section 6.

**Definition 3.1.** A pair of subgroups $B$ and $N$ of a group $G$ is called a BN-pair if $B$ and $N$ generate $G$, the intersection $T := B \cap N$ is normal in $N$, and the quotient $W = N/T$ admits a set of generators $S$ such that the following two conditions hold:

- (BN1) For $s \in S$ and $w \in W$ we have $sBw \subseteq BsB \cup BwB$.
- (BN2) For $s \in S$, we have $sBs^{-1} \not\subseteq B$.

The group $W$ is called the Weyl group of the BN-pair. The quadruple $(G, B, N, S)$ is called Tits system.

We now describe the BN-pair on $G(K)$ which will be relevant for us. We mostly stick to the notation used in [Sou79]. Choose a maximal torus $T \subseteq G$. This fixes two subgroups $T(k) \subseteq G(k)$ and $T(K) \subseteq G(K)$. Fix a choice of Borel subgroup $\overline{B}$ in $G(k)$ containing $T(k)$.

For the definition of the BN-pair, we let $B \subseteq G(K)$ be the preimage of $\overline{B}$ under the reduction $G(O) \to G(k)$. The group $N$ is defined as the normalizer of $T(K)$ in $G(K)$.

This is the usual construction, explained in detail for the case $SL_n$ in [AB08] Section 6.9. We will not recall the proof that this indeed yields a BN-pair here.

We recall one particular description of the building associated to a BN-pair from [AB08] Section 6.2.6]. Given a Tits system $(G, B, N, S)$, a subgroup $P \subseteq G$ is called parabolic if it contains a conjugate of $B$. The subgroups of $G$ which contain $B$ are called standard parabolic subgroups. These are associated to subsets of $S$.

The building $\Delta(G, B)$ for $(G, B, N, S)$ is the simplicial complex associated to the ordered set of parabolic subgroups of $G$, ordered by reverse inclusion. The group $G$ acts via conjugation. The fundamental apartment is given by

$$\Sigma = \{wPw^{-1} \mid w \in W, P \geq B\}.$$
The other apartments are of course obtained by using conjugates of the group $B$ above. Alternatively, the building can be described as the simplicial complex associated to the ordered set of cosets of the standard parabolic subgroups, with the group $G$ acting via multiplication.

3.2. Soulé’s fundamental domain. We continue to consider the BN-pair defined above. In the standard apartment $\Sigma$ of $\Delta(G, B)$, there is one vertex fixed by $G(O)$. This vertex is denoted by $\phi$. The fundamental chamber containing the vertex $\phi$ is given by

$$C = \{ P \mid P \geq B \} \subseteq \Sigma.$$  

The fundamental sector $Q$ is the simplicial cone with vertex $\phi$ which is generated by $C$.

The following theorem was proved in [Sou79] and subsequently generalized to isotropic simply-connected absolutely almost simple groups, cf. [Mar09].

**Theorem 3.2.** The set $Q$ is a simplicial fundamental domain for the action of $G(k[t])$ on the Bruhat-Tits building $\Delta(G, B)$. In other words, any simplex of $\Delta(G, B)$ is equivalent under the action of $G(k[t])$ to a unique simplex of $Q$.

3.3. Stabilizers. We are also interested in the subgroups which stabilize simplices in the fundamental domain $Q$. We have seen above that the simplices correspond to standard parabolic subgroups. It turns out that the stabilizer of the simplex corresponding to $G \geq P \geq B$ is exactly $P$, cf. [AB08, Theorem 6.43]. In particular, for the group $G(k[t])$, we find that the stabilizer of a simplex $\sigma_P$ corresponding to a parahoric subgroup $P$ of $G(K)$ is the following intersection

$$\text{Stab}(\sigma_P) = G(k[t]) \cap P.$$  

This implies a concrete description of the stabilizers, cf. [Sou79, Paragraph 1.1] resp. [Mar09, Proposition 2.5].

**Proposition 3.3.** Let $x \in Q \setminus \{\phi\}$. We denote by $\text{Stab}(x)$ the stabilizer of $x$ in $G(k[t])$.

(i) There is an extension of groups

$$1 \rightarrow \text{Stab}(x) \cap U_x(K) \rightarrow \text{Stab}(x) \rightarrow L_x(k) \rightarrow 1.$$  

The group $L_x(k)$ is a reductive subgroup of $G(k)$, in fact it is a Levi subgroup of a maximal parabolic subgroup of $G(k)$ for the spherical BN-pair. The group $\text{Stab}(x) \cap U_x(K)$ is a split unipotent subgroup of $U_x(k[t])$.

(ii) The stabilizer of a simplex $\sigma$ is the intersection of the stabilizers of the vertices $x$ of $\sigma$.

(iii) The stabilizers can be described using the valuation of the root system, cf. [Sou79, Section 1.1]. In particular, in the notation of Soulé, we have

$$\Gamma_x = L_x(k) \cdot U_x(k[t]), \quad L_x(k) = T(k) \cdot \langle x_\alpha(k) \mid \alpha(x) = 0 \rangle,$$

$$U_x(k[t]) = \langle x_\alpha(u) \mid u \in k[t], d \circ (u) \leq \alpha(x), \alpha(x) > 0 \rangle.$$  

Without explaining all the notation in detail, this means that an element of $Z_x(k) = L_x(k)$ is a product of an element of the torus and certain root elements, where the roots only depend on the vertex $x$. An element in $U_x(k[t])$ is a product of certain root elements, the degree of the polynomials and the roots only depend on the vertex $x$. 
4. Homology of the stabilizers and Knudsen’s theorem

In this section, we describe the homology of the stabilizers of simplices in Soulé’s domain. In \[\text{[Knu07]}, \text{Knudsen showed in the case } SL_n \text{ that the homology of the stabilizers is determined by the homology of a Levi subgroup. We provide below a generalization of this result. The results work in general for rings with many units. From Proposition 3.3} \]

we know that for a simple group $\sigma$ in the fundamental domain $Q$, the stabilizer $\Gamma_\sigma = \text{Stab}(\sigma)$ of $\sigma$ in $G(k[l])$ sits in an extension

$$1 \to U_\sigma \to \Gamma_\sigma \to L_\sigma \to 1,$$

where $U_\sigma$ is an abstract group contained in a unipotent subgroup $G(k[l])$ and $L_\sigma$ is the group of $k$-points of a reductive subgroup of $G$. The first thing we will show in this section is that the induced morphism $H_*(\Gamma_\sigma, \mathbb{Z}) \to H_*(L_\sigma, \mathbb{Z})$ is an isomorphism. This is done via the Hochschild-Serre spectral sequence

$$E^2_{p,q} = H_p(L_\sigma, H_q(U_\sigma)) \Rightarrow H_{p+q}(\Gamma_\sigma)$$

associated to the above group extension. To show the result, it suffices to show that $H_p(L_\sigma, H_q(U_\sigma)) = 0$ for $q > 0$.

The basic idea for showing this latter assertion is to use the action of $k^\times$ on the group $U_\sigma$, where $k^\times$ is embedded in $L_\sigma$ as the $k$-points of a suitable subtorus. The group $k^\times$ acts via multiplication on the various abelian subquotients constituting the unipotent group $U_\sigma$, and an argument as in \[\text{[Knu01] Theorem 2.2.2}\] shows that this homology is trivial. This argument is detailed after some introductory remarks in \[\text{Theorem 4.6}\].

4.1. A result of Suslin. A ring $A$ is an $S(n)$-ring if there are $a_1, \ldots, a_n \in A^\times$ such that the sum of each nonempty subfamily is a unit. If $A$ is an $S(n)$-ring for all $n$, then $A$ is said to have many units.

As explained in \[\text{[Knu01] Section 2.2.1}\], the right way to prove that

$$H_p(GL_n(A), H_q(M_{n,m}(A), \mathbb{Z})) = 0$$

for $q > 0$ if $A$ is a $\mathbb{Q}$-algebra is the following: we notice that $M_{n,m}(A)$ is an abelian group, and therefore $H_q(M_{n,m}(A)) = \wedge^q M_{n,m}(A)$. There exists a central element $a \in GL_n(A)$ which acts on $M_{n,m}(A)$ by multiplication with $a$, and therefore by multiplication with $a^q$ on $H_q(M_{n,m}(A))$. This action is trivial, because $a$ is in the center, and therefore $H_q(M_{n,m}(A))$ is annihilated by $a^q - 1$. But it is a $\mathbb{Q}$-vector space and therefore it is trivial for $q > 0$.

The following result due to Nesterenko and Suslin \[\text{[NS90]}\] is a generalization of this center kills argument to rings with many units in arbitrary characteristics. For more information on the proof of this result, cf. \[\text{[Knu01] Section 2.2.1}\].

**Proposition 4.1.** Let $A$ be a ring with many units, and let $F$ be a prime field. Then for all $i \geq 0$ and $j > 0$, we have $H_i(A^\times, H_j(A^\times, F)) = 0$, where $A^\times$ acts diagonally on $A^\times$.

The same conclusion also obtains for actions of $A^\times$ via non-zero powers of units, cf. \[\text{[Hui90] Lemma 9}\].

4.2. Example: orthogonal groups. We explain the procedure using the special case of orthogonal groups from \[\text{[Vog79]}\]. For the groups $O_{n,k}$ over a field $k$ of characteristic $\neq 2$, there are maximal parabolic subgroups $P_1$ which have a non-abelian unipotent radical. They have the following general form, cf. \[\text{[Vog79] p. 21}\]:

$$
\begin{pmatrix}
A & * & * \\
0 & B & * \\
0 & 0 & tA^{-1}
\end{pmatrix},
$$
where \( A \in GL_p(k) \), \( B \in O_{n-p,n-p}(k) \) and there are some additional conditions on the \( s \)-terms ensuring that the whole matrix is in \( O_{n,n}(k) \). It is proved on p.34 of that paper that the unipotent subgroup \( N \) of \( P_I \) sits in an exact sequence

\[
0 \to [N, N] \to N \to N/[N, N] \to 0
\]

with the outer terms \([N, N]\) and \( N/[N, N]\) abelian groups. It is also proved that the torus

\[
\text{diag}(a, \ldots, a, 1, \ldots, 1, a^{-1}, \ldots, a^{-1})
\]

acts via multiplication with \( a \) on \( N/[N, N] \) and multiplication with \( a^2 \) on \([N, N]\).

We apply the Hochschild-Serre spectral sequence for the extension

\[
0 \to [N, N] \to P_I \to P_I/[N, N] \to 1.
\]

This has the following form:

\[
H_p(P_I/[N, N], H_q([N, N])) \Rightarrow H_{p+q}(P_I).
\]

To prove that \( H_p(P_I/[N, N], H_q([N, N])) = 0 \) for \( q > 0 \), we use another Hochschild spectral sequence for the torus action:

\[
H_p(P_I/[N, N]/k^\times, H_q(k^\times, H_q([N, N])) \Rightarrow H_{p+q}(P_I/[N, N], H_q([N, N])).
\]

Since the action of \( k^\times \) on \([N, N]\) is via multiplication by squares, the result of Suslin [Proposition 4.1] implies \( H_p(P_I/[N, N], H_q([N, N])) = 0 \) for \( q > 0 \).

The morphism \( P_I \to P_I/[N, N] \) thus induces an isomorphism on homology. A similar argument applied to the extension

\[
1 \to N/[N, N] \to P_I/[N, N] \to P_I/N \to 1
\]

implies that the morphism \( P_I/[N, N] \to P_I/N \) also induces an isomorphism on homology.

This amounts to a proof of [Vog79, Proposition 2.2] for infinite fields of characteristic \( p \neq 2 \). We obtain the following strengthening of Vogtmann’s stability result, making explicit a remark in [Knu01, Section 2.4.1].

**Corollary 4.2.** Let \( k \) be an infinite field of characteristic \( \neq 2 \). Then the induced morphisms

\[
H_i(O_{n,n}(k), \mathbb{Z}) \to H_i(O_{n+1,n+1}(k), \mathbb{Z})
\]

is surjective for \( n \geq 3i + 1 \) and an isomorphism for \( n \geq 3i + 3 \).

**Remark 4.3.** The above example for orthogonal groups is an instance of a more general result which can be found e.g. in [ABS90]. Let \( G \) be a reductive group over \( k \), let \( \Phi \) be the associated root system and assume that char \( k \) is not equal to 2 for \( \Phi \) doubly laced resp. not equal to 2 or 3 for \( \Phi \) triply laced. Let \( P \) be a parabolic subgroup associated to a subset \( I \subseteq \Phi \) of simple roots, and let \( U \) be the unipotent radical of \( P \). Then the length of the descending central series of \( U \) equals \( \sum_{\alpha \in I} m(\alpha) \) where \( \alpha \) is the multiplicity of \( \alpha \) in the highest root \( \tilde{\alpha} \) of \( \Phi \).

In the above example of orthogonal groups, the root system is of type \( D_n \). Numbering the simple roots \( \alpha_1, \ldots, \alpha_{n-1}, \alpha_n \) such that \( \alpha_1, \alpha_{n-1} \) and \( \alpha_n \) correspond to the end-points of the Dynkin diagram, the longest root is

\[
\tilde{\alpha} = \alpha_1 + 2\alpha_2 + \cdots + 2\alpha_{n-2} + \alpha_{n-1} + \alpha_n.
\]

The parabolic subgroups discussed in the above example are the ones corresponding to roots \( \alpha_2, \ldots, \alpha_{n-2} \).
4.3. Homology of the stabilizers. We now want to compute the homology of the stabilizers. We formulate the proof with the $k$-points of the stabilizers, where $k$ is an infinite field. The same arguments show the result more generally for an integral domain $R$ with many units having quotient field $k$. The goal is to compute the homology of the stabilizer $\Gamma_{\sigma}(k[t])$. The Levi subgroup $L_{\sigma}$ is defined as $L_{\sigma} = Z_G(S_{\sigma})$, i.e. as the centralizer of a split torus $S_{\sigma}$ in $G$ associated to the simplex $\sigma$. We note that it follows from this definition that there is a normal central torus in $L_{\sigma}$.

Now consider a subtorus $G \to L_{\sigma}$. If the corresponding abstract group $k^{\times}$ acts trivially on the $k$-points of a unipotent subgroup $U \subseteq G(k[t])$, then $U \subseteq Z_G(G_m)$ and hence $U$ is contained in $L_{\sigma}$. Therefore, for any unipotent subgroup $U \subseteq \Gamma_{\sigma}$ which is not contained in $L_{\sigma}$, there has to exist a torus $G_m \subseteq L_{\sigma}$ such that the corresponding group of $k$-points $k^{\times}$ acts nontrivially on the $k$-points of $U$.

Note that the unipotent radicals $U_\sigma$ of parabolic subgroups of $G$ associated to the simplex $\sigma$ are actually split, i.e. there is a filtration

$$U_\sigma = U_1 \supseteq U_2 \supseteq \cdots \supseteq U_n = \{1\}$$

with each $U_i/U_{i+1}$ being isomorphic to $G_a$. Since the automorphism group of $G_a$ is $G_m$, the multiplicative group $G_m$ can only act via

$$(a \in k^{\times}, u \in k) \mapsto a^n u$$

for some $n$. We have thus established the following:

Lemma 4.4. Let $U_\sigma$ be the unipotent radical of the stabilizer $\Gamma_{\sigma}$, and let

$$U_\sigma = U_1 \supseteq U_2 \supseteq \cdots \supseteq U_n = \{1\}$$

be a filtration such that $U_i/U_{i+1} \cong G_a$. For each $i$, there exists a central embedding $k^{\times} \to L_{\sigma}$ and a number $n_i$ such that $a \in k^{\times}$ acts on $U_i/U_{i+1}$ via multiplication with $a^{n_i}$.

Note that above we are only talking about algebraic groups, i.e. about the unipotent radical of parabolic subgroups of $G(k[t])$. However, since the $k[t]$-points of the torus are $k^{\times}$, the action preserves the degree filtration of the $k[t]$-points of unipotent radicals. In particular, the action described above restricts to an action of $k^{\times}$ on the unipotent part $U_\sigma$ of the stabilizer subgroup $\Gamma_{\sigma}$, for any simplex $\sigma \in \mathcal{Q}$.

Example 4.5. (i) The simplest example of this situation is the embedding

$$R^{\times} \to SL_{n+m} : a \mapsto \text{diag}(a^n, \ldots, a^n, a^{-n}, \ldots, a^{-n}).$$

The centralizer of this torus is the Levi subgroup of a maximal parabolic subgroup which is the intersection of the following subgroup with $SL_{n+m}$:

$$\left( \begin{array}{cc} GL_n & 0 \\ 0 & GL_m \end{array} \right).$$

The corresponding parabolic subgroup has the form

$$\left( \begin{array}{cc} GL_n & M \\ 0 & GL_m \end{array} \right) \cap SL_{n+m}$$

and the torus acts on $M$ via multiplication with $a^{m+n}$, cf. \cite{Hutz90}.

(ii) Another example of such a situation is the one discussed in the proof of Corollary 4.2, cf. also \cite{Vogt79} p. 34. In these cases, the unipotent radical of a maximal parabolic of a split orthogonal or symplectic group is not abelian, and the torus acts via different powers on the steps of the central series.

\hfill \Box
The above actions now allow to compute the $E_2$ term of the Hochschild-Serre spectral sequence. This is done by using the composition series of $U_I$, which induces a sequence
\[
\Gamma_I \to \Gamma_I/U_a = \Gamma_I/U_n \to \Gamma_I/U_2 \to \cdots \to \Gamma_I/U_I = L_I.
\]
We will show below that each step induces isomorphisms on homology. The argument is a generalization of the proof of [Knu97, Corollary 3.2].

The following theorem now describes the homology of the stabilizers of the action of $G(k)$ on the Bruhat-Tits building.

**Theorem 4.6.** Let $R$ be an integral domain with many units and denote by $k = Q(R)$ its field of fractions. The group $G(R[t])$ acts on the Bruhat-Tits building associated to the group $G(k(t))$, and we consider the stabilizer group $\Gamma_\sigma$ of a simplex $\sigma \in Q$. Then the morphism
\[
H_\bullet(\Gamma_\sigma, \mathbb{Z}) \to H_\bullet(L_\sigma, \mathbb{Z})
\]
induced from the projection in Proposition 3.3 is an isomorphism.

**Proof.** Consider the composition series of $U_\sigma$:
\[
U_\sigma = U_1 \supseteq U_2 \supseteq \cdots \supseteq U_n = \{1\}.
\]
More precisely, the composition series of the unipotent group as an algebraic group induces a similar filtration of the unipotent part of the stabilizer, which is defined inside the unipotent radical by degree bounds as in Proposition 3.3. This induces a sequence of group homomorphisms
\[
\Gamma_\sigma \to \Gamma_\sigma/U_n \to \Gamma_\sigma/U_2 \to \cdots \to \Gamma_\sigma/U_\sigma = L_\sigma.
\]
Each step in this sequence is a quotient by a subgroup of $G_a(R[t])$ in $\Gamma_\sigma/U_i$. It therefore suffices to show that each such morphism induces an isomorphism on homology. This is done via the Hochschild-Serre spectral sequence, which then looks like
\[
H_p((\Gamma_\sigma/U_i+1)/R^\times, H_l(U_i/U_{i+1}, F)) \Rightarrow H_p(\Gamma_\sigma/U_i, \mathbb{Z}).
\]
Thus it suffices to show for any prime field $F$, we have
\[
H_p(\Gamma/U_{i+1}, H_q(U_i/U_{i+1}, F)) = 0
\]
for $q > 0$. But by [Lemma 4.4] there is a central embedding $R^\times \to \Gamma/U_{i+1}$ such that $a \in R^\times$ acts on $U_i/U_{i+1}$ via multiplication by some non-zero power of $a$.

We have an associated Hochschild-Serre spectral sequence
\[
H_j((\Gamma_\sigma/U_i+1)/R^\times, H_l(R^\times, H_q(U_i/U_{i+1}, F))) \Rightarrow H_{j+l}(\Gamma_\sigma/U_{i+1}, H_q(U_i/U_{i+1}, F)).
\]
From Proposition 3.3 we obtain that $H_l(R^\times, H_q(U_i/U_{i+1}, F)) = 0$ for $q > 0$, which finishes the proof.

\[\square\]

4.4. **The theorem of Knudsen.** We will now prove homotopy invariance in the one-variable case. The following is a generalization of [Knu01, Corollary 4.6.3].

**Theorem 4.7.** Let $k$ be an infinite field and let $G$ be a reductive group over $k$. Then the inclusion $k \hookrightarrow k[t]$ induces an isomorphism
\[
H_\bullet(G(k), \mathbb{Z}) \cong H_\bullet(G(k[t]), \mathbb{Z}),
\]
if the order of the fundamental group of $G$ is invertible in $k$.
Proof. By [Proposition 2.2] we can assume that $G$ is simply-connected absolutely almost simple over $k$. Then we can use the action of the group $G(k[t])$ on the building associated to $G(k(t))$. By [Theorem 3.2] the subcomplex $Q$ is a fundamental domain for this action. There is an associated spectral sequence

$$E^1_{p,q} = \bigoplus_{\dim \sigma = p, \sigma \in Q} H_q(\Gamma_\sigma, \mathbb{Z}) \Rightarrow H_{p+q}(G(k[t]), \mathbb{Z}).$$

In the above, $\Gamma_\sigma$ is the stabilizer of the simplex $\sigma$. This is the spectral sequence computing the $G(k[t])$-equivariant homology of the building, cf. [Knu01, p. 162].

From [Theorem 4.3] we know the homology of the stabilizers, in particular, that it only depends on the reductive part. In the notation of [Knu97], there is a filtration of the fundamental domain $Q$ via subsets $E^{(k)}_I$ for any $k$-element subset $I$ of roots of $G$. These subsets are simplicial subcones of $Q$ which consist of all simplices of $Q$ such that the constant part of the stabilizer is the standard parabolic subgroup of $G$ determined by the subset $I$. This yields a filtration

$$Q^{(k)} = \bigcup_I E^{(k)}_I.$$

Now for any two simplices $\sigma, \tau$ in

$$E^{(k)}_I \setminus \bigcup_{j \in I} E^{(k-1)}_J,$$

the stabilizers $\Gamma_\sigma$ and $\Gamma_\tau$ have the same reductive part $L_\sigma = L_\tau$, and therefore they also have the same homology, by [Theorem 4.3]. The coefficient system $\sigma \mapsto H_q(\Gamma_\sigma)$ is then locally constant in the sense of [Knu01, Proposition A.2.7], and we obtain an isomorphism

$$H_\bullet(\phi, \mathcal{H}_q) \to H_\bullet(Q, \mathcal{H}_q).$$

This shows that the argument in the proof of [Knu97, Theorem 3.4] does not depend on $SL_n$. Therefore, [Knu01, Proposition A.2.7] implies that the $E_2$-term of the above spectral sequence looks as follows:

$$E^2_{p,q} = \begin{cases} H_q(G(k), \mathbb{Z}) & p = 0 \\ 0 & p > 0 \end{cases}$$

The spectral sequence degenerates and the result is proved. \(\square\)

Remark 4.8. (i) [Theorem 4.6] has been used in [Wen12] to establish homotopy invariance for the homology of Steinberg groups of rank two groups.

(ii) Apart from the application mentioned in (i), it seems that the added generality of rings with many units in [Theorem 4.6] can not be widely applied. Generalizations of [Theorem 4.7] beyond the case $k[t]$ seem to be generally wrong. The failure of homotopy invariance for $H_1$ of $SL_2$ follows directly from [KM97]. The failure of homotopy invariance for $H_2$ of rank two groups has been established in [Wen12]. In these cases, one sees that $Q$ fails quite badly to be a fundamental domain for the action of $G(R[t])$ if $R$ is not a field – in case $SL_2$, the subcomplex $SL_2(R[t]) \cdot Q$ is not connected and in case $SL_3$, the subcomplex $SL_3(R[t]) \cdot Q$ is not simply-connected.

Concerning the subcomplex $G(R[t]) \cdot Q$ for $R$ an integral domain, we have the following:

Proposition 4.9. (i) The complex $E(R[t]) \cdot Q$ is connected.

(ii) The complex $G(R[t]) \cdot Q$ is connected if $G(R[t]) = E(R[t]) \cdot G(R)$. This in particular holds for $R$ essentially smooth over a field.

(iii) The complex $E(R[t]) \cdot Q$ is simply-connected if $K_2^G(R[t]) \cong K_2^G(R)$, in particular for $G = SL_n$, $n \geq 5$ and $R = k[t_1, \ldots, t_n]$. 
Proof. Every elementary matrix for a positive root is contained in some stabilizer, and the stabilizer of \( \phi \) contains the Weyl group. By [Son79, Theorem 2] the complex \( E(\Phi, R[t]) \cdot Q \) is connected, hence (i). The same argument shows (ii). The additional consequence in (ii) is the work of Suslin [Sus77], Abe [Abe83] and in the non-split case Stavrova [Sta11]. We only sketch (iii): it follows from the assumption on homotopy invariance of \( K_2 \) that \( E(R[t]) \) is an amalgam of the stabilizers along their intersections. Again [Son79, Theorem 2] shows the claim. The additional assertion for \( SL_n \) is a consequence of [Tub82]. \( \square \)

5. On the degree 3 case of the Friedlander-Milnor conjecture

We recall the singular resolution of a linear algebraic group, cf. [Jar83]:

**Definition 5.1.** Let \( k \) be a field. There is a standard simplicial \( k \)-algebra \( k[\Delta^n] \) with \( n \)-simplices given by

\[
k[\Delta^n] = k[X_0, \ldots, X_n]/(\sum X_i - 1)
\]

and face and degeneracy maps given by

\[
d_i(X_j) = \begin{cases} X_j & j < i \\ 0 & j = i \\ X_{j-1} & j > i \end{cases},
\]

\[
s_i(X_j) = \begin{cases} X_j & j < i \\ X_i + X_{i+1} & j = i \\ X_{j+1} & j > i \end{cases}.
\]

For a linear algebraic group \( G \) we consider the simplicial group \( G(k[\Delta^n]) \), its \( n \)-simplices can be considered (after choosing a representation \( G \hookrightarrow GL_n \) and an isomorphism \( k[T_1, \ldots, T_n] \cong k[X_0, \ldots, X_n]/(\sum X_i - 1) \)) as matrices with entries polynomials in \( n \) variables.

This is a “topologized” version of the algebraic group \( G \) which plays a central role in Morel’s approach to the Friedlander-Milnor conjecture [Mor12]. Morel has shown that the Friedlander-Milnor conjecture for a group \( G \) follows if one can prove that the inclusion \( G(k) \hookrightarrow G(k[\Delta^n]) \) induces isomorphisms on homology with \( \mathbb{Z}/\ell\mathbb{Z} \)-coefficients for algebraically closed fields of characteristic \( \neq \ell \). Morel also announced a proof of this weak version of homotopy invariance. The results of the present paper allow to deduce a special case of weak homotopy invariance:

**Proposition 5.2.**

(i) Let \( k \) be an infinite field, and let \( G \) be a simply-connected Chevalley group of rank at least 2. Then the inclusion \( G(k) \hookrightarrow G(k[\Delta^n]) \) induces isomorphisms

\[
H_i(BG(k), \mathbb{Z}) \rightarrow H_i(BG(k[\Delta^n]), \mathbb{Z})
\]

for \( i \leq 3 \).

(ii) Let \( k \) be an infinite field and let \( G \) be an isotropic reductive group satisfying the following conditions

- the relative root system is of rank \( \geq 2 \) and of type \( A_n, B_n, C_n, D_n, E_6, E_7, \) or \( E_8 \),
- if the absolute root system is not simply laced, then \( \text{char}(k) \neq 2 \).

(iii) Let \( k \) be an infinite field. Then the inclusion \( SL_n(k) \hookrightarrow SL_n(k[\Delta^n]) \) induces isomorphisms

\[
H_i(BSL_n(k), \mathbb{Z}) \rightarrow H_i(BSL_n(k[\Delta^n]), \mathbb{Z})
\]

for \( i \leq 4 \) and \( n \geq 5 \).

**Proof.** The classifying space of the simplicial group \( G(k[\Delta^n]) \) is naturally a bisimplicial object. In this situation, there is a spectral sequence computing the homology of the diagonal, which has the form

\[
E^2_{p,q} = H_p(H_q(BG(k[\Delta^n]), \mathbb{Z}))) \Rightarrow H_{p+q}(dBG(k[\Delta^n]), \mathbb{Z}).
\]
The \( E^2 \)-term can be described more precisely as follows: first one takes the homology of the classifying spaces \( BG(k[\Delta^n]) \). The simplicial algebra structure on \( k[\Delta^\bullet] \) induces for each \( q \) a complex

\[
\cdots \to H_q(BG(k[\Delta^n]), \mathbb{Z}) \to H_q(BG(k[\Delta^{n-1}]), \mathbb{Z}) \to \cdots
\]

The \((p, q)\)-entry of the \( E^2 \)-page is the \( p \)-th homology of the above complex.

We collect what we can say about the \( E^2 \)-page. First, by Theorem 4.7, the column \( p = 0 \) contains \( H_n(G(k), \mathbb{Z}) \) and the column \( p = 1 \) contains only zeroes. The row \( q = 0 \) obviously contains only zeroes for \( p > 0 \). If \( H_i(G(k), \mathbb{Z}) \cong H_i(G(k[t_1, \ldots, t_n]), \mathbb{Z}) \) for all \( n \), then the row \( q = i \) contains only zeroes for \( p > 0 \).

Assuming all rows \( 0 < q \leq j \) to be trivial as above, no differential can change the entries with \( p + q \leq j + 2 \) because the first possibly non-trivial entry in the upper right quadrant is at \((2, j + 1)\). In particular, the spectral sequence shows

\[
H_i(G(k), \mathbb{Z}) \cong H_i(G(k[\Delta^\bullet]), \mathbb{Z})
\]

equation for \( i \leq j + 2 \). With this, we can now proceed with the proof.

(i) By \([\text{Sus87}]\) and \([\text{Abe83}]\), cf. also \([\text{Wen10}]\), together with the fact that the elementary subgroups are the commutator subgroups for groups of rank at least 2, we obtain isomorphisms \( H_i(G(k), \mathbb{Z}) \to H_i(G(k[t_1, \ldots, t_n]), \mathbb{Z}) \) for all \( n \). This shows the claim.

(ii) follows in the same way using the main result of \([\text{Sta11}]\).

For (iii), one uses additionally the result of Tulenbaev \([\text{Tul82}]\) which shows \( H_2(SL_n(k), \mathbb{Z}) \cong H_2(SL_n(k[t_1, \ldots, t_n]), \mathbb{Z}) \) for all \( n \).

**Remark 5.3.** Obviously, the above spectral sequence would show \( H_\bullet(G(k), \mathbb{Z}) \cong H_\bullet(G(k[\Delta^\bullet]), \mathbb{Z}) \) if the strong form of homotopy invariance were true, i.e.

\[
H_\bullet(G(k), \mathbb{Z}) \cong H_\bullet(G(k[t_1, \ldots, t_n]), \mathbb{Z}) \text{ for all } n.
\]

However, by the results of \([\text{KM97}]\) and \([\text{Wen12}]\), this is known to be false for \( n \geq 2 \) and \( G \) of rank \( \leq 2 \). For the time being, we have to be satisfied with weaker results.

Using Morel’s weak form of the Friedlander-Milnor conjecture from \([\text{Mor12}]\), the above result allows to prove the degree 3 case of Friedlander’s generalized isomorphism conjecture. Such a result in degree 3 was previously known for \( GL_n \) over fields of positive characteristic, cf. \([\text{Knu01}]\), Corollary 5.5.5. Note that Morel has recently announced a proof of the full Friedlander-Milnor conjecture.

**Corollary 5.4.** Let \( K \) be an algebraically closed field, let \( G \) be a simply-connected Chevalley group of rank at least 2 and let \( \ell \) be a prime with \((\ell, \text{char } K) = 1\). Then the natural homomorphism

\[
H^3_{\ell}(BG_K, \mathbb{Z}/\ell\mathbb{Z}) \to H^3(BG(K), \mathbb{Z}/\ell\mathbb{Z})
\]

is an isomorphism.

**Proof.** This follows from Morel’s weak form of the generalized isomorphism conjecture, cf. \([\text{Mor12}]\) Theorem 3], together with the above \([\text{Proposition 5.2}]\) case (i).

**Remark 5.5.**

(i) Note that \( H^3_{\ell}(BG_K, \mathbb{Z}/\ell\mathbb{Z}) = 0 \) for \( G \) simply-connected and \( K \) algebraically closed of characteristic \( \neq \ell \).

(ii) Of course, one could also use \([\text{Proposition 5.2}]\) case (iii) to prove Friedlander’s generalized isomorphism conjecture for \( H^3 \) of \( SL_n \), \( n \geq 5 \). However, this already follows from Suslin’s proof of rigidity for algebraic K-theory \([\text{Sus83}]\) and the stability theorems of Hutchinson and Tao \([\text{HT10}]\).
