RIEFFEL PROPER ACTIONS

ALCIDES BUSS AND SIEGFRIED ECHTERHOFF

Abstract. In the late 1980’s Marc Rieffel introduced a notion of properness for actions of locally compact groups on C*-algebras which, among other things, allows the construction of generalised fixed-point algebras for such actions.

In this paper we give a simple characterisation of Rieffel proper actions and use this to obtain several (counter) examples for the theory. In particular, we provide examples of Rieffel proper actions $\alpha : G \to \text{Aut}(A)$ for which properness is not induced by a nondegenerate equivariant $*$-homomorphism $\phi : C_0(X) \to M(A)$ for any proper $G$-space $X$. Other examples, based on earlier work of Meyer, show that a given action might carry different structures for Rieffel properness with different generalised fixed-point algebras.

1. Introduction

In [21] Marc Rieffel introduced a notion of proper actions (which we call Rieffel proper actions below) of a group $G$ on a C*-algebra $A$ which allows the construction of a generalised fixed-point algebra $A^G$ together with a natural Morita equivalence bimodule between this algebra and a suitable ideal of the reduced crossed product $A \rtimes_{\alpha,r} G$. Rieffel’s notion of properness depends on a choice of a dense $*$-subalgebra $A_0$ of $A$ which must satisfy a number of quite technical conditions (see §2 below). One of these conditions requires that for all $\xi, \eta \in A_0$ the functions $t \mapsto \langle \langle \xi | \eta \rangle \rangle(t) : = \Delta(t)^{-1/2} \xi^* \alpha_t(\eta)$ lie in $L^1(G, A) \subseteq A \rtimes_{\alpha,r} G$. Rieffel’s conditions allow the construction of a corresponding generalised fixed-point algebra $A^G \subseteq M(A)$ and an equivalence bimodule $\mathcal{F}(A_0)$ between $A^G$ and the closed ideal $I_{A_0} \subseteq A \rtimes G$ generated by all elements of the form $\{\langle \langle \xi | \eta \rangle \rangle : \xi, \eta \in A_0\}$.

In this paper we show that an action $\alpha : G \to \text{Aut}(A)$ is Rieffel proper if and only if there exists a dense subspace (not necessarily a subalgebra) $R \subseteq A$ which satisfies the following single condition:

(P1) For all $\xi, \eta \in R$ the functions $t \mapsto \xi^* \alpha_t(\eta)$ and $t \mapsto \Delta(t)^{-1/2} \xi^* \alpha_t(\eta)$ belong to $L^1(G, A)$.

If $A_0 \subseteq A$ is a dense $*$-subalgebra which satisfies Rieffel’s original conditions, it also satisfies (P1). We show that, conversely, if $R$ is as above, then there is a canonical construction of a dense $*$-subalgebra $A_R$ which satisfies Rieffel’s conditions. As easy corollaries we get the following useful results:

(1) Assume $A$ and $B$ are $G$-algebras such that there exists a nondegenerate $G$-equivariant $*$-homomorphism $\phi : A \to M(B)$. Then, if $A$ is Rieffel proper, so is $B$.

(2) If $A$ is a Rieffel proper $G$-algebra and $B$ is a Rieffel proper $H$-algebra, then $A \otimes_\nu B$ is a Rieffel proper $G \times H$-algebra, where $\otimes_\nu$ might denote the minimal or maximal tensor product.

These basic results seem to have been not noticed for general Rieffel proper $G$-algebras, although the first of these results is well known in the case $A = C_0(X)$ for some proper $G$-space $X$. Indeed, most standard examples of Rieffel proper actions of a group $G$ on a $C^*$-algebra $B$, like dual actions of groups on crossed products by coactions, come naturally equipped with a nondegenerate $\ast$-equivariant $\ast$-homomorphism $\phi : C_0(X) \to \mathcal{M}(B)$ for some proper $G$-space $X$, and actions with this extra property have been studied extensively in the literature (e.g., see [1,2,3,6]). Following [3,6], we shall call such actions to be weakly proper. It has been shown in [4] that weakly proper actions enjoy many properties which are (so far) unknown for general Rieffel proper actions. The most remarkable one is that they allow analogous constructions of the Hilbert $A \rtimes_{\alpha,\varphi} G$-module $\mathcal{F}(A_0)$ for the universal crossed products $A \rtimes_{\alpha} G := A \rtimes_{a,u} G$ and of corresponding universal generalised fixed-point algebras $A^G_\alpha$ with many interesting properties. Looking at the vast number of examples of weakly proper actions, we were wondering, whether every Rieffel proper action is also weakly proper.

In §3 we show that this is not the case. Using our characterisation of Rieffel proper actions together with Rieffel’s deformation $C_0(\mathbb{R}^n)_J$ of $C_0(\mathbb{R}^n)$ by a skew-symmetric matrix $J \in \mathfrak{m}_n(\mathbb{R})$, we show that the dual action of the Pontrjagin dual $\hat{G}$ of an abelian locally compact group $G$ on any twisted group algebra $C^*(G,\omega)$ attached to any $2$-cocycle $\omega \in Z^2(G,\mathfrak{t})$ is Rieffel proper. On the other hand, if $G$ is connected, we can show that this dual action is weakly proper only if $\omega$ is similar to the trivial cocycle. This shows that there are many natural examples of Rieffel proper actions which are not weakly proper.

In the final section §4 we study the question whether the generalised fixed-point algebra $A^G$ of a Rieffel proper action $\alpha : G \to \text{Aut}(A)$ is independent of the choice of the dense subalgebra $A_0 \subseteq A$ (or the dense subspace $R \subseteq A$ of our condition (P1)). Indeed, examples for a dependence on similar structures have been constructed already by Ralf Meyer in the setting of “continuously square-integrable actions”, which we here call “Exel-Meyer proper actions”: these are based on the theory of square-integrable actions (see [10,15,16]) and generalise Rieffel proper actions. Using our main result, we show that many of Meyer’s examples are also Rieffel proper, hence also provide examples for the dependence of the fixed-point algebra $A^G$ on the choice of the dense subalgebra $A_0$ in this setting. To our knowledge, this provides the first examples for this dependence in the setting of Rieffel proper actions.

The authors are grateful to Sergey Neshveyev for some helpful discussions on Rieffel deformation theory that led us to the examples in §3.

Most of this work has been carried out through a visit of the second author at the Department of Mathematics of the Federal University of Santa Catarina. He thanks the members of the department for their warm hospitality and CAPES for making this visit possible.

2. Rieffel proper actions

Suppose $G$ is a locally compact group acting by a strongly continuous homomorphism $\alpha : G \to \text{Aut}(A)$ on the $C^*$-algebra $A$. Then, in [21, Definition 1.2], Rieffel defines this action to be proper (which we call Rieffel proper) if there exists a dense $G$-invariant $\ast$-subalgebra $A_0$ of $A$ such that for all $\xi, \eta \in A_0$:

(P1) the functions $t \mapsto \Delta(t)^{-1/2} \xi^\ast \alpha_t(\eta)$ and $t \mapsto \xi^\ast \alpha_t(\eta)$ belong to $L^1(G, A)$;

(P2) there is a (necessarily unique) element $m = \alpha^\ast(\xi \eta) \in \mathcal{M}(A)^{G,\alpha}$ such that $\alpha^\ast(\xi \eta) \zeta = \int_G \alpha_t(\xi \eta^t) \zeta \, dt$ for all $\zeta \in A_0$; and
Remark

The space of all square-integrable elements of $A$ above.

A class of actions is strictly bigger than the Rieffel proper actions of \[21\] as recalled above. $A$ is\(\xi,\eta\) form classically integrable if the net of Bochner integrals

One says that a measurable function $f$ is integrable if the strict-unconditional integral

Rieffel shows in \[21\] that $A^{G,\alpha} := \operatorname{span}(A^\alpha(\xi|\eta) : \xi,\eta \in A_0) \subseteq \mathcal{M}(A)$ is a $C^*$-subalgebra of $\mathcal{M}(A)$ and that $A_0$ equipped with the inner product $A^\alpha(\xi|\eta)$ completes to give a left Hilbert $A^{G,\alpha}$-module $F(A_0) := \overline{A_0}$. The $C^*$-algebra $A^{G,\alpha}$ (or simply $A^\alpha$ if the action $\alpha$ is clear) is called the \textit{generalised fixed-point algebra} for the proper action $\alpha$ (with respect to $A_0$). Clearly, if $G$ is compact, this coincides with the classical fixed-point algebra for any dense $A_0 \subseteq A$. Rieffel also shows that $F(A_0)$ carries a right Hilbert module structure over the reduced crossed product $A \rtimes_{\alpha,r} G$ in such a way that $F(A_0)$ is a Hilbert $A^{G,\alpha} - A \rtimes_{\alpha,r} G$-bimodule.

The module $F(A_0)$ can be concretely described as the completion of $A_0$ with respect to the Hilbert $A^{G,\alpha} - A \rtimes_{\alpha,r} G$-bimodule structure given by the formulas:

$$
\langle \xi | \eta \rangle_{A \rtimes_{\alpha,r} G}(t) := \Delta(t)^{-1/2} \xi^* \alpha_t(\eta), \quad \xi, \eta \in A_0, t \in G
$$

$$
\xi * \varphi := \int_G \Delta(t)^{-1/2} \alpha_t(\xi \varphi(t^{-1}))dt,
$$

$$
A^\alpha(\xi|\eta)^* := \int_G \alpha_t(\xi(\eta^*)^*) dt,
$$

$$
m \cdot \xi := ma \quad \text{(product in } \mathcal{M}(A)).
$$

Here the first formula gives an element in $L^1(G, A) \subseteq A \rtimes_{\alpha,r} G$ and the second formula works for all $\varphi \in L^1(G, A)$ for which the integral provides an element in $A_0$. The bimodule $F(A_0)$ is always full as a left Hilbert $A^{G,\alpha}$-module, but the right inner product is not full in general since the ideal $I = \operatorname{span}\{\langle A_0 | A_0 \rangle_{A \rtimes_{\alpha,r} G}\} \subseteq A \rtimes_{\alpha,r} G$ may be proper. The action $\alpha : G \to \operatorname{Aut}(A)$ is called \textit{saturated} (with respect to $A_0$) if this ideal is all of $A \rtimes_{\alpha,r} G$. Then $F(A_0)$ becomes a Morita equivalence between $A^{G,\alpha}$ and $A \rtimes_{\alpha,r} G$. In general, $F(A_0)$ becomes a Morita equivalence between $A^{G,\alpha}$ and the ideal $I = \operatorname{span}\{\langle A_0 | A_0 \rangle_{A \rtimes_{\alpha,r} G}\} \subseteq A \rtimes_{\alpha,r} G$.

Remark 2.1. We should note that the module $F(A_0)$ described above is actually the dual of the $A \rtimes_{\alpha,r} G - A^{G,\alpha}$ module as constructed originally by Rieffel in \[21\].

It is tempting to write $A^\alpha(\xi|\eta)$ as a sort of integral $\int_G \alpha_t(\xi \eta^*) dt$. Although this integral cannot converge as a Bochner integral in general, one can make sense of it as a \textit{strict-unconditional integral} as defined in \[9, 10\]:

\textbf{Definition 2.2.} One says that a measurable function $f : G \to A$ is strictly unconditionally integrable if the net of Bochner integrals $\int_K f(t) dt$ for $K$ running over all compact subsets of $G$ (ordered by inclusion) converges in the strict topology of $\mathcal{M}(A)$; the strict limit is then denoted by $\int_G^\alpha f(t) dt$.

If $(A, \alpha)$ is a $G$-algebra, an element $\xi \in A$ is called \textit{square-integrable} if the function $t \mapsto \alpha_t(\xi^*)$ is strictly unconditionally integrable. We write $A_{ai}$ for the space of all square-integrable elements of $A$. The \textit{space of integrable elements} $A_i$ is then defined as the linear span of $A_{ai}A_{ai}^*$, i.e., linear combinations of elements of the form $\xi \eta^*$ with $\xi, \eta \in A_{ai}$. The $G$-algebra $(A, \alpha)$ is \textit{integrable} if $A_i$ (or equivalently $A_{ai}$) is dense in $A$.

Rieffel calls integrable actions also “proper” in \[22\], but as shown in \[16\] this class of actions is strictly bigger than the Rieffel proper actions of \[21\] as recalled above.

In \[22\] Proposition 4.6] Rieffel shows that (P1) and the density of $A_0$ implies the existence of the strict-unconditional integrals $\int_G^\alpha \alpha_t(\xi \eta^*) dt$, so that $A_0 \subseteq A_{ai}$ and hence $A$ is an integrable $G$-algebra. More precisely, the proof of Proposition 4.6 in \[22\] shows the following:

\textbf{Proposition 2.3.} Suppose $\mathcal{R}$ is a dense subspace (not necessarily a $*$-subalgebra) such that the functions $t \mapsto \xi^* \alpha_t(\eta)$ belong to $L^1(G, A)$ for all $\xi, \eta \in \mathcal{R}$. Then
The above proposition has been generalised in [16, Proposition 6.5], where it is also verified that the set of all \[ \langle \langle R | R \rangle \rangle \subseteq \text{span}(R, A) \] is a dense subspace of \( A \). Hence, next we show that only the first condition (P1) is necessary in order to get a Rieffel proper action. For this we first interpret these functions as kernels of certain “Laurent operators”, as explained in [16] or in [10]; see also §4 below) for \( \xi, \eta \in A \) or in \( A \). Indeed, next we show that if \( \Delta(t)^{-1/2} \xi \alpha_t(\eta) \) belong to \( A \times_{\alpha, r} G \) for all \( \xi, \eta \) in a dense subspace of \( A \).

The proposition shows that there are some redundancies in Rieffel’s original definition of a proper action in [21]. Indeed, next we show that only the first condition (P1) is necessary in order to get a Rieffel proper action. For this we first need to fix some notations.

Given any elements \( \xi, \eta \in A \), we shall always write \( \langle \xi \mid \eta \rangle \) for the continuous function \( t \mapsto \Delta(t)^{-1/2} \xi \alpha_t(\eta) \), even if this is not in \( L^1(G, A) \) or in \( A \times_{\alpha, r} G \).

Also, given \( \xi \in A \) and \( \varphi : G \to A \) a measurable function, we write \( \xi \ast \varphi := \int_G \Delta(t)^{-1/2} \alpha_t(\xi \varphi(t^{-1})) \, dt \) whenever this makes sense. We shall use the notation:

\[
L^1_G(G, A) := L^1(G, A) \cap \Delta^{1/2} L^1(G, A) \cap \Delta^{-1/2} L^1(G, A) \\
= \{ f \in L^1(G, A) : \Delta^{-1/2} f \text{ and } \Delta^{1/2} f \in L^1(G, A) \}.
\]

It is easy to verify the relations:

\[
\Delta^p(f \ast g) = (\Delta^p f) \ast (\Delta^p g), \quad (\Delta^p f)^* = (\Delta^p f)^*
\]

for any power \( p \in \mathbb{R} \). In particular it follows that \( L^1_G(G, A) \) is a *-subalgebra of \( L^1(G, A) \). It is a dense subalgebra because it contains \( C_c(G, A) \).

**Proposition 2.5.** An action \( (A, \alpha) \) is Rieffel proper if and only if there is a dense subspace \( \mathcal{R} \subseteq A \) such that for all \( \xi, \eta \in \mathcal{R} \), we have

\[
\langle \xi \mid \eta \rangle = \left( t \mapsto \Delta(t)^{-1/2} \xi \alpha_t(\eta) \right) \in L^1(G, A) \cap \Delta^{-1/2} L^1(G, A).
\]

In this case, \( \langle \mathcal{R} \mid \mathcal{R} \rangle \subseteq L^1_G(G, A) \) and \( A_0 := \text{span}(\mathcal{R} \ast L^1_G(G, A)) \cdot (\mathcal{R} \ast L^1_G(G, A))^* \) is a dense *-subalgebra of \( A \) which satisfies Rieffel’s conditions (P1)–(P3). Hence \( (A, \alpha) \) is Rieffel proper with respect to \( A_0 \).

**Proof.** If the action is Rieffel proper with respect to a dense *-subalgebra \( A_0 \), we simply take \( \mathcal{R} = A_0 \). Conversely, given \( \mathcal{R} \) as in the proposition, we will show that \( A_0 = \text{span}(\mathcal{R} \ast L^1_G(G, A)) \cdot (\mathcal{R} \ast L^1_G(G, A))^* \) satisfies Rieffel’s conditions (P1)–(P3). For this we will see that if \( \mathcal{R} \subseteq A \) is a dense subspace of \( A \) satisfying (P1), then \( \langle \mathcal{R} \mid \mathcal{R} \rangle \subseteq L^1_G(G, A) \). Moreover, \( \mathcal{R} := \text{span} \mathcal{R} \ast L^1_G(G, A) \) is then automatically a \( G \)-invariant dense right ideal of \( A \) also satisfying

\[
\langle \mathcal{R} \mid \mathcal{R} \rangle \subseteq L^1_G(G, A).
\]
Then, \( A_0 := \text{span} \hat{R} \hat{R}^* \) is a \( G \)-invariant dense \( * \)-subalgebra of \( A \) contained in \( \hat{R} \) which satisfies (P1)-(P3).

Given \( \xi, \eta \in R \), we have \( \langle \xi | \eta \rangle^* = \langle \eta | \xi \rangle \) and \( (\Delta^{1/2} \langle \xi | \eta \rangle)^* = \Delta^{-1/2} \langle \eta | \xi \rangle \), where involution is taken inside \( L^1(G, A) \). Therefore, \( \langle R | R \rangle \subseteq L^1(G, A) \cap \Delta^{-1/2} L^1(G, A) \) is equivalent to \( \langle R | R \rangle \subseteq L^1(G, A) \cap \Delta^{1/2} L^1(G, A) \) and hence also equivalent to \( \langle R | R \rangle \subseteq L^1_\Delta(G, A) \).

Now, given \( f, g \in L^1_\Delta(G, A) \), we have \( \langle \xi * f | \eta * g \rangle = f^* \langle \xi | \eta \rangle * g \). Since \( L^1_\Delta(G, A) \) is a \( * \)-subalgebra of \( L^1(G, A) \), it follows that \( \hat{R} = R \ast L^1_\Delta(G, A) \) satisfies \( \langle \hat{R} | \hat{R} \rangle \subseteq L^1_\Delta(G, A) \). That \( \hat{R} \) is a right ideal follows from the identity \( \langle \xi * f | a \rangle = \langle \xi * (f \cdot a) \rangle \), where \( f \cdot a(t) := f(t) a(t) \). And that \( \hat{R} \) is \( G \)-invariant follows from \( a \ast \xi * f = \xi * (t \cdot f) \), where \( t \cdot f(s) := \Delta(t)^{-1/2} f(st) \). It follows that \( A_0 = \text{span} \hat{R} \hat{R}^* \subseteq \hat{R} \) is a \( G \)-invariant dense \( * \)-subalgebra of \( A \). Since (P1) and (hence also) (P2) hold for \( \hat{R} \), they also hold for \( A_0 \subseteq \hat{R} \). Finally notice that

\[
A^G_0 \langle \hat{R} | \hat{R} \rangle \hat{R} = \hat{R} \ast \langle \hat{R} | \hat{R} \rangle_{AXG} \subseteq \hat{R} \ast L^1_\Delta(G, A) \subseteq \hat{R}
\]

so that \( A^G_0(A_0 | A_0) A_0 \subseteq A^G_0(\hat{R} | \hat{R}) \hat{R} \hat{R}^* \subseteq \hat{R} \hat{R}^* \subseteq A_0 \), i.e., (P3) holds for \( A_0 \). \( \square \)

One can also use the subspace \( \hat{R} \) above, or more generally, any dense subspace \( \mathcal{R} \subseteq A \) satisfying

\[
\langle \mathcal{R} | \mathcal{R} \rangle = L^1_\Delta(G, A) \quad \text{and} \quad R \ast L^1_\Delta(G, A) \subseteq \mathcal{R}
\]

to build a pre-Hilbert \( A^G_0 = A \ast_{\alpha,r} G \)-bimodule \( F_0(\mathcal{R}) \). More precisely, if \( \mathcal{R} \) is such a subspace, we can view \( \mathcal{R} \) as a right pre-Hilbert module over \( L^1_\Delta(G, A) \subseteq A \ast_{\alpha,r} G \) with \((\xi, \eta) \mapsto \langle \xi | \eta \rangle\) as the inner product and the “convolution” \( \xi * \varphi = \int_G \Delta(t)^{-1/2} a(t) \varphi(t^{-1}) dt \) as the right action. That these are indeed well-defined operations and have the correct properties (in particular, that \( \langle \xi | \xi \rangle \) is positive in \( A \ast_{\alpha,r} G \)) follows from the same arguments as used by Rieffel in [21]. Also, the same arguments show that

\[
A^G_0 := \text{span} A^G_0 \langle \mathcal{R} | \mathcal{R} \rangle = \text{span} \left\{ \int_G \alpha_t(\xi \varphi^*) dt : \xi, \varphi \in \mathcal{R} \right\}
\]

is a \( * \)-subalgebra of \( \mathcal{M}(A)^G \), and that the multiplication in \( \mathcal{M}(A) \) and the pairing \((\xi, \eta) \mapsto A^G_0(\xi | \eta)\) give \( \mathcal{R} \) the structure of a pre-Hilbert \( A^G_0 = L^1_\Delta(G, A) \)-bimodule.

Defining then \( A^G \) to be the closure of \( A^G_0 \) in \( \mathcal{M}(A) \), and completing \( \mathcal{R} \) with respect to the norm coming from one of the inner products, one gets a Hilbert \( A^G = A \ast_{\alpha,r} G \)-module \( F(\mathcal{R}) \). We should also point out that such ideas have been already performed in [16] in a slightly more general context for Hilbert modules and where the inner products \( \langle \xi | \eta \rangle \) do not necessarily lie in \( L^1_\Delta(G, A) \), but only in \( A \ast_{\alpha,r} G \) in general. We refer to [4] for a more detailed discussion of this.

**Proposition 2.7.** Let \( \mathcal{R} \subseteq A \) be a dense subspace satisfying (P4), and define \( \hat{\mathcal{R}} := \text{ran} \mathcal{R} \ast L^1_\Delta(G, A) \subseteq \mathcal{R} \) and \( A_0 := \text{span} \hat{\mathcal{R}} \hat{\mathcal{R}}^* \). Then all Hilbert bimodules \( F(\mathcal{R}) \), \( F(\hat{\mathcal{R}}) \) and \( F(\mathcal{R}) \) are canonically isomorphic.

**Proof.** The inclusions \( A_0 \subseteq \hat{\mathcal{R}} \subseteq \mathcal{R} \) extend to embeddings \( F(A_0) \hookrightarrow F(\hat{\mathcal{R}}) \hookrightarrow F(\mathcal{R}) \) of Hilbert \( A \ast_{\alpha,r} G \)-modules. To show that these embeddings are isomorphisms, it is enough (by the Rieffel Correspondence Theorem [20 Corollary 3.33]) to show that the ideals

\[
\text{span} \langle A_0 | A_0 \rangle \subseteq \text{span} \langle \hat{\mathcal{R}} | \hat{\mathcal{R}} \rangle \subseteq \text{span} \langle \mathcal{R} | \mathcal{R} \rangle
\]

of \( A \ast_{\alpha,r} G \) coincide. To see this first observe from a simple computation that

\[
\langle \xi * f | \eta * g \rangle = f^* \ast \langle \xi | \eta \rangle \ast g \quad \text{and} \quad \langle \xi a | \eta b \rangle = i_A(a)^*(\xi | \eta) i_A(b)
\]

for all \( \xi, \eta \in \mathcal{R} \), \( f, g \in C_c(G, A) \), and \( a, b \in A \), where \( (i_A(a) f)(t) := a f(t) \) and \( (f i_A(a))(t) := f(t) a(t) \). Note that the latter formulas determine the canonical
inclusion $i_A : A \to \mathcal{M}(A \rtimes_{\alpha,r} G)$. Since $\tilde{R}^*$ is a dense left ideal of $A$, there exists a bounded right approximate unit $(e_i)$ of $A$ in $\tilde{R}^*$. It follows then from the second equation in (2.5) that 

$$\langle \langle \xi | \eta \rangle \rangle = i_A(e_i^*) \langle \langle \xi | \eta \rangle \rangle i_A(e_i) \to \langle \langle \xi | \eta \rangle \rangle,$$

for all $\xi, \eta \in \tilde{R}$, which shows that $\tilde{\text{span}}\langle \langle A_0 | A_0 \rangle \rangle = \tilde{\text{span}}\langle \langle \tilde{R} | \tilde{R} \rangle \rangle$. Choosing a self-adjoint approximate unit $(\varphi_i)$ of $A \rtimes_{\alpha,r} G$ in $C_r(G, A) \subseteq L^\Delta(G, A)$, we get

$$\langle \langle \xi \ast \varphi_i | \eta \ast \varphi_i \rangle \rangle = \varphi_i \ast \langle \langle \xi | \eta \rangle \rangle \ast \varphi_i \to \langle \langle \xi | \eta \rangle \rangle$$

for all $\xi, \eta \in \tilde{R}$, which proves $\tilde{\text{span}}\langle \langle \tilde{R} | \tilde{R} \rangle \rangle = \tilde{\text{span}}\langle \langle R | R \rangle \rangle$. \hfill \Box

**Remark 2.9.** Let $(A, \alpha)$ be a $G$-algebra and suppose that $A_0 \subseteq A$ is a $G$-invariant dense $^\ast$-subalgebra of $A$ which satisfies Rieffel’s conditions (P1)–(P3). It follows not necessarily from these conditions that $A_0 \ast L^\Delta(G, A) \subseteq A_0$, hence it is not necessarily true that $A_0$ satisfies (2.8). However, it is clear that $\tilde{\mathcal{R}} := A_0 \ast L^\Delta(G, A)$ must be contained in the intersection of Rieffel’s module $\mathcal{F}(A_0) = \tilde{A}_0$ with $A$. Using approximate units $(\varphi_i)$ in $C_r(G, A)$ as above, it follows that we get $\mathcal{F}(A_0) = \mathcal{F}(\tilde{\mathcal{R}}) = \mathcal{F}(\tilde{\mathcal{R}}^\ast)$, so we see that applying our procedure to $\mathcal{R} := A_0$ leads to the original Hilbert bimodule $\mathcal{F}(A_0)$ of Rieffel’s and the corresponding fixed-point algebra.

The following facts, which apparently have not been noticed before in the literature, are now easy consequences of our characterisation of Rieffel proper actions and will be used frequently in this paper. For notation, if $(A, \alpha)$ is a $G$-algebra and if $\mathcal{R} \subseteq A$ is as in Proposition 2.9, then we shall say that $\alpha : G \to \text{Aut}(A)$ is Rieffel proper with respect to $\mathcal{R} \subseteq A$.

**Corollary 2.10.** Suppose that $\alpha : G \to \text{Aut}(A)$ is Rieffel proper with respect to the dense subspace $\mathcal{R}_A \subseteq A$. Let $(B, \beta)$ be another $G$-algebra and let $\Phi : A \to \mathcal{M}(B)$ be a nondegenerate $G$-equivariant $^\ast$-homomorphism. Then $\beta : \text{Aut}(B) \to \text{Aut}(\mathcal{R}_B) := \Phi(\mathcal{R}_A) B \subseteq B$. Moreover, there is a canonical isomorphism of Hilbert $B \rtimes_{\beta,r} G$-modules:

$$\mathcal{F}(\mathcal{R}_B) \cong \mathcal{F}(\mathcal{R}_A) \otimes_{\Phi \times_{A,G}} B \rtimes_{\beta,r} G,$$

where $\Phi \times_{A,G} : A \rtimes_{\alpha,r} G \to \mathcal{M}(B \rtimes_{\beta,r} G)$ denotes the (nondegenerate) $^\ast$-homomorphism associated to $\Phi$. In particular, if $\mathcal{R} = A$ is saturated with respect to $\mathcal{R}_A$, then $\mathcal{R}$ is saturated with respect to $\mathcal{R}_B$.

**Proof.** Since $\Phi$ is nondegenerate, $\mathcal{R}_B$ is dense in $B$. Let $x, y \in \mathcal{R}_A$, $b, c \in B$ and let $\xi = \Phi(x)b$ and $\eta = \Phi(y)c$. Then $s \mapsto \langle \langle x | y \rangle \rangle(s) \in L^\Delta(G, A)$, and hence we get $s \mapsto \langle \langle \xi \rangle \rangle(s) = \Phi(\langle \langle x | y \rangle \rangle(s)) \beta_r(c) \in L^\Delta(G, B)$. The final assertion is a particular case of Corollary 7.1 in [16] by using the canonical isomorphism $B \cong A \otimes_{\Phi} B$ as $G$-equivariant Hilbert $B$-modules and the fact that Rieffel proper actions are proper in the sense of Exel-Meyer, as we shall explain in §3 below. \hfill \Box

**Corollary 2.11.** Suppose that $\alpha : G \to \text{Aut}(A)$ and $\beta : H \to \text{Aut}(B)$ are Rieffel proper with respect to $\mathcal{R}_A \subseteq A$ and $\mathcal{R}_B \subseteq B$, respectively. Then $\alpha \otimes \beta : G \times H \to \text{Aut}(A \otimes \nu B)$ is proper with respect to $\mathcal{R}_A \otimes \mathcal{R}_B \subseteq A \otimes \nu B$, where $\otimes \nu$ denotes either the maximal or the minimal tensor product of $A$ with $B$.

**Proof.** If $\xi_1, \xi_2 \in \mathcal{R}_A$ and $\eta_1, \eta_2 \in \mathcal{R}_B$, then

$$\langle \langle \xi_1 \otimes \eta_1 | \xi_2 \otimes \eta_2 \rangle \rangle(s, h) = \langle \langle \xi_1 | \xi_2 \rangle \rangle(s) \cdot \langle \langle \eta_1 | \eta_2 \rangle \rangle(h)$$

lies in $L^\Delta(G \times H, A \otimes \nu B)$. \hfill \Box
Corollary 2.12. Suppose that $N$ is a compact normal subgroup of $G$ and let $\alpha : G/N \rightarrow \text{Aut}(A)$ be Rieffel proper with respect to $R_A \subseteq A$. Then the inflated action $\alpha := \inf \alpha : G \rightarrow \text{Aut}(A)$ is also Rieffel proper with respect to $R_A$.

Proof. This follows immediately from the fact that in this situation a function $f : G/N \rightarrow A$ is integrable if and only if the function $f \circ q$ is integrable over $G$, when $q : G \rightarrow G/N$ denotes the quotient map. \hfill \Box

3. Properness of dual actions on twisted group algebras

Recall that for any abelian locally compact group $G$ and any Borel 2-cocycle $\omega \in Z^2(G, \mathbb{T})$ the twisted group algebra $C^*(G, \omega)$ is a $C^*$-completion of the Banach algebra $L^1(G, \omega)$ consisting of all $L^1$-functions on $G$ with convolution and involution twisted by $\omega$ as follows:

$$f \ast g(t) = \int_G f(s)g(t-s)\omega(s, t-s)\, ds \quad \text{and} \quad f^*(s) = \overline{\omega(s, -s)f(-s)}.$$

The same convolution formula defines a $^*$-representation

$$\lambda_\omega : L^1(G, \omega) \rightarrow B(L^2(G)); \quad \lambda_\omega(f)\xi = f \ast \xi$$

(which makes sense for $\xi \in L^1(G) \cap L^2(G)$) and then

$$C^*(G, \omega) := \overline{\lambda_\omega(L^1(G, \omega))} \subseteq B(L^2(G)).$$

There is a canonical dual action $\hat{\omega} : \hat{\hat{G}} \rightarrow \text{Aut}(C^*(G, \omega))$ of the dual group $\hat{\hat{G}}$ on $C^*(G, \omega)$ which is given on the dense subalgebra $L^1(G, \omega)$ by

$$\hat{\omega}_\chi(f) = \chi \cdot f, \quad \forall \chi \in \hat{\hat{G}}, f \in L^1(G, \omega).$$

We want to show in this section that this action is always Rieffel proper.

For a detailed study of twisted group algebras of abelian groups we refer to the paper [3]. Note that two cocycles $\omega$ and $\omega'$ are called similar (or cohomologous) if there exists a Borel function $c : G \rightarrow \mathbb{T}$ such that $\omega'(s, t) = c(s)c(t)c(st)\omega(s, t)$ for all $s, t \in G$. In this case the mapping $f \mapsto c \cdot f$ (pointwise multiplication) on $L^1$-functions extends to an isomorphism $C^*(G, \omega) \cong C^*(G, \omega')$ which commutes with the dual actions. Thus for our purposes it is enough to fix any representative of $\omega$ under similarity, or, equivalently, to look at classes in $H^2(G, \mathbb{T}) = Z^2(G, \mathbb{T})/\sim$.

If $\omega \in Z^2(G, \mathbb{T})$, then there is a continuous homomorphism $h_\omega : G \rightarrow \hat{\hat{G}}$ given by

$$h_\omega(s)(t) = \omega(s, t)\overline{\omega(t, s)}.$$}

It is shown in [3] that two cocycles $\omega$ and $\omega'$ on the abelian group $G$ are similar if and only if $h_\omega = h_{\omega'}$. Moreover, if $S_\omega := \ker h_\omega = \{ s \in G : \omega(s, t) = \omega(t, s) \, \forall t \in G \}$ denotes the symmetrizer group of $\omega$, then Baggett and Kleppner show in [3] Theorem 3.1 that $\omega$ is always similar to a cocycle inflated from some cocycle $\tilde{\omega}$ on $G/S_\omega$.

In what follows we shall need the following basic fact on computing the cohomology group $H^2(G, \mathbb{T}) = Z^2(G, \mathbb{T})/\sim$ for abelian groups $G$, which is actually a very special case of Mackey’s formula [14] Proposition 9.6 together with [12] Propositions 1.4 and 1.6.

Lemma 3.1. Suppose $G = H \times N$ is the direct product of the abelian locally compact groups $H$ and $N$ such that one of them is locally euclidean. Then every cocycle $\omega \in Z^2(G, \mathbb{T})$ is similar to a product $\omega_H \cdot \omega_N$, where $\omega_H$ and $\omega_N$ are the restrictions of $\omega$ to $H$ and $N$, respectively, and $\eta : H \times N \rightarrow \mathbb{T}$ is a continuous bi-character and $\omega_\eta((h_1, n_1), (h_2, n_2)) = \eta(h_1, n_2)$. 

RIEFFEL PROPER ACTIONS 7
We also need the following well-known fact:

**Lemma 3.2.** Suppose that $K$ is a compact abelian group. Then every cocycle

$\omega \in Z^2(K, \mathbb{T})$ is similar to a cocycle inflated from a finite quotient $K/N$ of $K$.

**Proof.** Just observe that the kernel $S_\omega$ of $h_\omega : K \to \hat{K}$ is open in $K$ and hence has finite index in $K$. The result then follows from the above discussions. □

It follows from [3] p.314 that every cocycle on $\mathbb{R}^n$ is similar to one of the form

$\omega_J(s, t) = e^{2\pi i (J \cdot s, t)}$ for a unique skew-symmetric matrix $J \in \mathbb{M}_n(\mathbb{R})$ and that $C^*(\mathbb{R}^n, \omega_J)$ is commutative if and only if $J = 0$. In this case it follows from an easy exercise on Fourier transforms that

$$C^*(\mathbb{R}^n, \omega_J) = C^*(\mathbb{R}^n) \cong C_0(\mathbb{R}^n) \cong C_0(\mathbb{R}^n)$$

and the dual action of $\mathbb{R}^n \cong \hat{\mathbb{R}}^n$ on $C^*(\mathbb{R}^n)$ is transformed to the translation action on $C_0(\mathbb{R}^n)$.

In order to show that the dual actions of $\mathbb{R}^n$ on $C^*(\mathbb{R}^n, \omega_J)$ are Rieffel proper for all skew-symmetric $J$, we want to rely on Rieffel’s study of his $J$-deformed algebras $C_0(\mathbb{R}^n)_J$ of $C_0(\mathbb{R}^n)$. For this let $S(\mathbb{R}^n)$ be the Schwartz space of rapidly decreasing functions on $\mathbb{R}^n$ equipped with the translation action $\tau$ of $\mathbb{R}^n$. In [23][24] Rieffel considers the deformed multiplication $\times_J$ on $S(\mathbb{R}^n)$ given by the formula

$$f \times_J g(x) = \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} f(x - Ju)g(x - v)e^{2\pi i(u,v)} dv du.$$

We should note that in general this double integral only exists in the given order, and that Fubini’s theorem cannot be applied to it! We write $S(\mathbb{R}^n)_J$ for $S(\mathbb{R}^n)$ equipped with this multiplication. Rieffel shows that together with the involution $f^* (x) := f(\overline{x})$, $S(\mathbb{R}^n)_J$ becomes a *-algebra and there is a canonical faithful *-representation $L_J : S(\mathbb{R}^n)_J \to \mathcal{B}(L^2(\mathbb{R}^n))$ by bounded operators given by the formula $L_J(f)\xi = f \times_J \xi$ for $\xi \in S(\mathbb{R}^n) \subseteq L^2(\mathbb{R}^n)$. The completion $C_0(\mathbb{R}^n)_J := \sigma(S(\mathbb{R}^n)_J)$ with respect to the operator norm of $\mathcal{B}(L^2(G))$ is the $J$-deformation of $C_0(\mathbb{R}^n)$.

Rieffel shows in [24] §2 that the translation action $\tau$ of $\mathbb{R}^n$ on $S(\mathbb{R}^n)_J$ extends to an action (denoted $\tau_J$) of $\mathbb{R}^n$ on $C_0(\mathbb{R}^n)_J$ which is Rieffel proper with respect to the dense subalgebra $S(\mathbb{R}^n)_J$. The following lemma extends the above isomorphism $C^*(\mathbb{R}^n) \cong C_0(\mathbb{R}^n)$ to the case of non-zero $J$. The lemma must be known by Rieffel (see [25] p. 70), but we did not find an explicit proof in the literature. In what follows we write $S(\mathbb{R}^n, \omega_J)$ for the dense subalgebra of $L^1(\mathbb{R}^n, \omega_J)$ consisting of Schwartz functions.

**Lemma 3.3.** For every skew-symmetric matrix $J$ the Fourier transform

$\mathcal{F} : S(\mathbb{R}^n)_J \to S(\mathbb{R}^n, \omega_J), \quad f \mapsto \widehat{f}$

extends to a $\tau_J - \omega_J$-equivariant isomorphism $\Phi : C_0(\mathbb{R}^n)_J \to C^*(\mathbb{R}^n, \omega_J)$.

**Proof.** Recall that $\widehat{f}(u) = \int_{\mathbb{R}^n} f(x) e^{-2\pi i (x,u)} dx$. Then, for $f, g \in S(\mathbb{R}^n)$ one checks the formula $\int \times_J g = \hat{f} \ast \mathcal{G}$ (mentioned by Rieffel in [25] p. 70) as follows: First observe that

$$f \times_J g(x) = \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} f(x - Ju)g(x - v)e^{2\pi i(v,u)} dv du$$

$$= \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} f(x - Ju)g(v)e^{2\pi i(x - v,u)} dv du$$

$$= \int_{\mathbb{R}^n} f(x - Ju)\hat{g}(u)e^{2\pi i(x,u)} du.$$
Applying the Fourier transform to this expression gives
\[
\hat{f} \times_J \hat{g}(z) = \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} f(x - Ju) \hat{g}(u) e^{2\pi i (x \cdot u - z)} \, du \, dx
\]
\[
\equiv \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} f(x) \hat{g}(u) e^{-2\pi i (x \cdot J u - z \cdot u)} \, dx \, du
\]
\[
= \int_{\mathbb{R}^n} \hat{f}(z - u) \hat{g}(u) e^{-2\pi i (J u \cdot z - u \cdot u)} \, du
\]
\[
= \int_{\mathbb{R}^n} \hat{f}(u) \hat{g}(z - u) e^{2\pi i (J u \cdot z - u \cdot u)} \, du
\]
\[
= \hat{f} *_{\omega, J} \hat{g}(z),
\]
where in the second to last equation we used \( J' = -J \). The formula also shows that the Plancherel isomorphism \( F : L^2(\mathbb{R}^n) \to L^2(\mathbb{R}^n) \) induces a unitary equivalence between \( \lambda_\omega \circ \Phi \) and \( L_J \), which implies that \( \Phi \) is isometric with respect to the \( C^* \)-norms. □

As mentioned before, the above lemma combined with the results in [24, §2] yields the following:

**Corollary 3.4.** The dual actions of \( \mathbb{R}^n \) on \( C^*(\mathbb{R}^n, \omega_J) \) are always Rieffel proper with respect to \( S(\mathbb{R}^n, \omega_J) \).

We now use this fact to prove:

**Theorem 3.5.** Let \( G \) be any second countable abelian group and let \( \omega \in Z^2(G, \mathbb{T}) \). Then the dual action \( \hat{\omega} : G \to \text{Aut}(C^*(G, \omega)) \) is Rieffel proper and saturated.

**Proof.** Recall first that the structure theorem for abelian locally compact groups says that \( G \) is isomorphic to a direct product \( \mathbb{R}^n \times H \) for some \( n \in \mathbb{N}_0 \) such that \( H \) contains a compact open subgroup \( K \) (e.g. see [8, Theorem 4.2.1]). Let \( \hat{\omega} \) denote the restriction of \( \omega \) to \( \mathbb{R}^n \times K \). There are no non-trivial bicharacters \( \eta : \mathbb{R}^n \times K \to \mathbb{T} \), since any such \( \eta \) would induce a nontrivial homomorphism from \( K \) into \( \mathbb{R}^n \cong \mathbb{R}^n \).

It follows from Lemma [3.1] that \( \hat{\omega} \) is similar to the product \( \omega_{\mathbb{R}^n} \cdot \omega_K \), where \( \omega_{\mathbb{R}^n} \) and \( \omega_K \) denote the restrictions of \( \omega \) to \( \mathbb{R}^n \) and \( K \), respectively. It follows then from Lemma [3.2] that, after passing to a finite-index subgroup \( \hat{K} \subseteq K \), if necessary, we may assume without loss of generality, that \( \omega_K \) is similar to \( 1_K \). This implies that \( C^*(\mathbb{R}^n \times K, \hat{\omega}) \cong C^*(\mathbb{R}^n, \omega_{\mathbb{R}^n}) \otimes C^*(K, \omega_K) \cong C^*(\mathbb{R}^n, \omega_{\mathbb{R}^n}) \otimes C_0(\hat{K}) \).

Since the dual action of \( \mathbb{R}^n \) of \( \omega_{\mathbb{R}^n} \) is proper with respect to \( S(\mathbb{R}^n, \omega_{\mathbb{R}^n}) \) and the action of \( \hat{K} \) on \( C_0(\hat{K}) \) is proper with respect to \( C_0(\hat{K}) \), it follows from Corollary [2.11] that the dual action of \( \mathbb{R}^n \times K \cong \mathbb{R}^n \times \hat{K} \) on \( C^*(\mathbb{R}^n \times K, \hat{\omega}) \) is proper with respect to \( D_0 := S(\mathbb{R}^n, \omega_{\mathbb{R}^n}) \otimes \mathcal{F}^{-1}(C_0(\hat{K})) \), where \( \mathcal{F}_K : C^*(K) \to C_0(\hat{K}) \) denotes Fourier transform for \( K \).

Since \( L := \mathbb{R}^n \times K \) is a compact (normal) subgroup \( N := \mathcal{G}/L \). Hence it follows from Corollary [2.12] that the inflation of the dual action of \( \mathbb{R}^n \times K \) on \( C^*(\mathbb{R}^n \times K, \hat{\omega}) \) to \( \mathcal{G} \) is also Rieffel proper. Now, the restriction of the \( \omega \)-regular representation \( \lambda_\omega : G \to \mathcal{U}(L^2(G)) \) to \( \mathbb{R}^n \times K \) induces a \( \hat{G} \)-equivariant nondegenerate *-homomorphism, and hence the dual action of \( \hat{G} \) on \( C^*(G, \omega) \) is Rieffel proper with respect to \( C^*(G, \omega)_0 := \lambda_\omega(D_0)C^*(G, \omega) \) by Corollary [2.11].

Finally, to see that the dual action is also saturated, we simply note that \( C^*(G, \omega) \times_{\hat{G}} \mathcal{G} \) is isomorphic to the compact operators on \( L^2(G) \), which follows from general Takesaki-Takai duality for crossed products by twisted actions [15]. Since \( K(L^2(G)) \) is simple, the \( C^*(G, \omega) \times_{\hat{G}} \mathcal{G} \)-valued inner product on \( \mathcal{F}(C^*(G, \omega)_0) \) must be full. □
Given any action $\alpha : G \to \text{Aut}(A)$ of the abelian locally compact group $G$ on the $C^*$-algebra $A$ together with a 2-cocycle $\omega \in Z^2(G, \mathbb{T})$, we can form the Busby-Smith twisted action $(\alpha, \omega : 1_A)$ of $G$ on $A$ (we refer to [17] for details on crossed products by Busby-Smith twisted actions). It is then easily seen that the canonical embedding of $G$ into $\mathcal{M}(A \rtimes_{\alpha, \omega} G)$ is an $\omega$-representation, and therefore integrates to give a $\hat{G}$-equivariant $\ast$-homomorphism $\phi : C^*(G, \omega) \to \mathcal{M}(A \rtimes_{\alpha, \omega} G)$. Thus, as a direct consequence of Corollary 2.10, we get:

**Corollary 3.6.** Let $(A, \alpha)$ be any action of a second countable locally compact abelian group $G$ on a $C^*$-algebra $A$ and let $\omega$ be any Borel 2-cocycle on $G$. Then the dual action $\widehat{\alpha}_\omega$ of $\hat{G}$ on the twisted crossed product $A \rtimes_{\alpha, \omega} G$ is Rieffel proper and saturated.

Recall that an action $\alpha : G \to \text{Aut}(A)$ is called weakly proper if there exists a locally compact proper $G$-space $X$ together with a nondegenerate $\ast$-homomorphism $\phi : C_0(X) \to \mathcal{M}(A)$. It is well known that every weakly proper action is Rieffel proper. This has first been observed by Rieffel in [22], but follows also easily from Corollary 2.10 since for proper $G$-spaces $X$ the corresponding action of $G$ on $C_0(X)$ is Rieffel proper with respect to $A_0 = C_0(X)$. As mentioned in the introduction, weakly proper actions enjoy a number of nice properties which are unknown for general Rieffel proper actions. On the other hand, so far it seemed to be open (at least to us), whether the class of Rieffel proper actions really differs from the class of weakly proper actions, since most standard examples of Rieffel proper actions given in the literature, like dual actions on ordinary crossed products, are also weakly proper. In what follows next, we show that dual actions on twisted group algebras $C^*(G, \omega)$ for connected abelian groups $G$ are weakly proper if and only if the cocycle $\omega$ is similar to the trivial cocycle $1_G$, hence providing many examples of Rieffel proper actions which are not weakly proper.

We should note that the notion “weakly proper” has been introduced by the authors in [4] in order to differentiate them from proper actions in the (very strong) sense of Kasparov in which we have a proper $G$-space $X$ together with a nondegenerate $\ast$-homomorphism $\phi : C_0(X) \to \mathcal{ZM}(A)$, where $\mathcal{ZM}(A)$ denotes the center of the multiplier algebra $\mathcal{M}(A)$.

We need the following lemma, in which $\mathcal{M}(C^*(G, \omega))^\hat{G}$ denotes the classical fixed-point algebra:

$$\mathcal{M}(C^*(G, \omega))^\hat{G} = \{ m \in \mathcal{M}(C^*(G, \omega)) : \widehat{\omega}_\chi(m) = m \forall \chi \in \hat{G} \}.$$

**Lemma 3.7.** For any abelian locally compact group we have $\mathcal{M}(C^*(G, \omega))^\hat{G} = \mathbb{C}$.

Indeed, this lemma is a special case of a much more general result for locally compact quantum groups given by Vainerman and Vaes in [26 Theorem 1.11]. For readers which are not familiar with quantum group techniques we present a direct proof here:

**Proof of Lemma 3.7.** Consider the regular representation $\lambda_\omega : C^*(G, \omega) \to B(L^2(G))$ as introduced above. Since this is a nondegenerate representation, it extends to a faithful representation of $\mathcal{M}(C^*(G, \omega))$ on $B(L^2(G))$ which is then contained in the double commutant $\mathcal{VN}(C^*(G, \omega)) = \lambda_\omega(C^*(G, \omega))^\prime\prime \subseteq B(L^2(G))$. Let us define the right regular $\omega$-representation $\rho_\omega : G \to U(L^2(G))$ by

$$\left(\rho_\omega(s)\xi\right)(r) = \omega(r-s, s)\xi(r-s).$$

Then a short (but tricky) computation using the cocycle identity $\omega(s, t)\omega(s+t, r) = \omega(s, t+r)\omega(t, r)$ for $s, t, r \in \hat{G}$ shows that $\rho_\omega(s)$ commutes with $\lambda_\omega(t)$ (given by...
the formula \( \{ \lambda_\omega(t) \xi \}(r) = \omega(t, r - t) \xi(r - t) \) for all \( t \in G \) and hence with \( \lambda_\omega(f) = \int_G f(t)\lambda_\omega(t) \, dt \) for all \( f \in L^1(G, \omega) \). This shows that \( \rho_\omega(s) \in \nuN(C^*(G, \omega))' \).

Recall now that the dual action \( \hat{\omega} : \hat{G} \to \text{Aut}(C^*(G, \omega)) \) is given by \( \hat{\omega}_\chi(f) = \chi \cdot f \) for \( \chi \in \hat{G}, f \in L^1(G, \omega) \). Let \( U : \hat{G} \to \mathcal{U}(L^2(G)) \) be the unitary representation given by \( U_\chi \xi = \chi \cdot \xi \). Then a short computation shows that

\[
\lambda_\omega(\hat{\omega}_\chi(f)) = U_\chi \lambda_\omega(f) U_\hat{\chi}
\]

and hence the action extends uniquely to an action on \( \nuN(C^*(G, \omega)) \) via \( \hat{\omega}_\chi(T) := U_\chi TU_\hat{\chi} \). If \( T \in \nuN(C^*(G, \omega)) \) is invariant under this action, it follows that \( T \)

commutes with \( U_\chi \) for all \( \chi \in \hat{G} \). Taking the integrated form, it follows that \( T \)

commutes with \( \hat{U}(C^*(\hat{G})) \subseteq B(L^2(G)) \). But if we identify \( C^*(\hat{G}) \) with \( C_0(G) \) by Gelfand transformation and Pontrjagin duality, a short computation shows that

\[
\hat{U}(C^*(\hat{G})) = M(C_0(G)),
\]

where \( M : C_0(G) \to B(L^2(G)) \) denotes the representation by multiplication operators.

Hence we conclude that every \( T \) in the fixed-point algebra \( \nuN(C^*(G, \omega)) \) commutes with \( M(C_0(G)) \cup \rho_\omega(G) \). Now define a new cocycle \( \hat{\omega} \in Z^2(G, \mathbb{T}) \) by

\[
\hat{\omega}(s, t) = \omega(t, s) = \omega(s, t).
\]

The cocycle identity for \( \omega \) directly translates into the cocycle identity for \( \hat{\omega} \) and one easily checks that \( \rho_\omega = \lambda_\hat{\omega} \).

Consider the twisted dynamical system \( (C_0(G), G, \tau, \hat{\omega}) \) in the sense of Busby & Smith (e.g. see [17]). One then checks that \( (M, \rho_\omega) \) is a covariant representation of this system on \( L^2(G) \) whose integrated form maps \( C_0(G \times G) \subseteq L^1(G, C_0(G)) \) onto a dense subspace of \( K(L^2(G)) \).

Since \( T \) commutes with \( (M, \rho_\omega) \), it also commutes with \( K(L^2(G)) \), which implies that \( T \in C_1 \).

Since a generalised fixed-point algebra \( A^G \) for a \( G \)-algebra \( A \), if exists, must lie in the classical fixed-point algebra \( \mathcal{M}(A)^G \) of \( \mathcal{M}(A) \), we directly get:

**Corollary 3.8.** The generalised fixed-point algebra \( C^*(G, \omega)^G \) with respect to any dense subspace \( \mathcal{R} \subseteq C^*(G, \omega) \) which implements Rieffel properness of the dual action of \( \hat{G} \) on \( C^*(G, \omega) \) as in Proposition 3.9 is isomorphic to \( \mathbb{C} \).

We use the above result to show:

**Proposition 3.9.** Let \( G \) be a connected abelian group and let \( \omega \in Z^2(G, \mathbb{T}) \). Then the dual action of \( \hat{G} \) on \( C^*(G, \omega) \) is weakly proper if and only if \( \omega \) is similar to the trivial cocycle \( 1_G \).

**Proof.** If \( \omega \) is trivial, then \( C^*(G, \omega) \cong C_0(\hat{G}) \) with the usual translation action of \( \hat{G} \), which is weakly proper.

Suppose now that \( \omega \) is nontrivial. By the structure theorem for locally compact abelian groups we have \( G \cong \mathbb{R}^n \times K \) for some connected compact group \( K \). As in the proof of Theorem 3.5 we can argue that \( \omega \) is similar to a cocycle \( \omega_{\mathbb{R}^n} \cdot 1_K \), and hence \( C^*(G, \omega) \cong C^*(\mathbb{R}^n, \omega_{\mathbb{R}^n}) \otimes C_0(\hat{K}) \). Assume now that there exists a \( \hat{G} \)-equivariant nondegenerate \(*\)-homomorphism \( \phi : C_0(X) \to \mathcal{M}(C^*(G, \omega)) \). Then the restriction of the dual action to the factor \( \mathbb{R}^n \) in \( \hat{G} = \mathbb{R}^n \times \hat{K} \) induces the structure a weakly proper action of \( \mathbb{R}^n \cong \mathbb{R}^n \) on \( C^*(G, \omega) \cong C^*(\mathbb{R}^n, \omega_{\mathbb{R}^n}) \otimes C_0(\hat{K}) \) such that the action on the second factor is trivial. Evaluation of the second factor at the trivial character \( 1_K \in \hat{K} \) induces an \( \mathbb{R}^n \)-equivariant quotient map \( C^*(\mathbb{R}^n, \omega_{\mathbb{R}^n}) \to C^*(\mathbb{R}^n, \omega_{\mathbb{R}^n}) \), which then induces the structure \( \phi : C_0(X) \to \mathcal{M}(C^*(\mathbb{R}^n, \omega_{\mathbb{R}^n})) \) of a weakly proper action of \( \mathbb{R}^n \) on \( C^*(\mathbb{R}^n, \omega_{\mathbb{R}^n}) \).

We need to show that this is impossible. For this observe that \( \mathbb{R}^n \) equipped with the translation action of \( \mathbb{R}^n \) is a model for the universal proper \( \mathbb{R}^n \)-space, i.e., if \( X \) is any proper \( \mathbb{R}^n \)-space, then there exists an \( \mathbb{R}^n \)-equivariant continuous
map $\psi : X \to \mathbb{R}^n$. This follows from the well know fact that any proper $\mathbb{R}^n$-space is a principal (i.e., locally trivial) $\mathbb{R}^n$-bundle (e.g., by Palais’s slice theorem), and that any principal $\mathbb{R}^n$-bundle is trivial by contractibility of $\mathbb{R}^n$ (e.g., see [11]). Hence we obtain a nondegenerate $\mathbb{R}^n$-map $\psi^* : C_0(\mathbb{R}^n) \to C_0(X) = M(C_0(X))$ by $\psi^*(f) = f \circ \psi$ and composing this with $\varphi$ we may assume without loss of generality that $X = \mathbb{R}^n$ (see also [5, Remark 3.13(d)]).

Assuming this we see that our assumption implies that $C^*(\mathbb{R}^n, \omega)$ is a weakly proper $\mathbb{R}^n \times \mathbb{R}^n$-algebra and hence it follows from Landstad duality for coactions of $\mathbb{R}^n$ (see [19] Theorem 3.3] or [4]), which in the present case is just Landstad duality for actions of $\mathbb{R}^n \cong \mathbb{R}^n$, that there exists an action $\alpha$ of $\mathbb{R}^n$ on the generalised fixed-point algebra $C^*(\mathbb{R}^n, \omega)^{\mathbb{R}^n}$ such that $C^*(\mathbb{R}^n, \omega) \cong C^*(\mathbb{R}^n, \omega)^{\mathbb{R}^n} \rtimes_{\alpha} \mathbb{R}^n$. It but follows from the construction of this fixed-point algebra (e.g., see [4]) that it must lie in the classical fixed-point algebra $M(C^*(\mathbb{R}^n, \omega))^{\mathbb{R}^n}$ which is $\mathbb{C}$ by Lemma 3.7. But the only action on $\mathbb{C}$ is the trivial one, and we conclude that $C^*(\mathbb{R}^n, \omega) \cong \mathbb{C} \rtimes \mathbb{R}^n \cong C^*(\mathbb{R}^n)$ is commutative, which contradicts the fact that $\omega$ is nontrivial.

Since actions of compact groups $K$ are always proper in any given sense (they are always Kasparov proper for the proper $K$-space $\{pt\}$), it is clear that for discrete groups $G$ the dual actions of $\hat{G}$ on $C^*(G, \omega)$ are always weakly proper. Indeed, this observation can be extended as follows:

Remark 3.10. Let $G = \mathbb{R}^n \times H$ be any abelian locally compact group such that the restriction of $\omega$ to $\mathbb{R}^n$ is trivial. Then as in the proof of Theorem 3.5 we may argue that there exists an open subgroup $M = \mathbb{R}^n \times K$ such that the restriction of $\omega$ to $M$ is trivial. Then the dual action of $\hat{M}$ on $C^* (M, \omega) \cong C_0(\hat{M})$ is weakly proper (with $X = \hat{M}$). Using the fact that $\hat{M} = \hat{G}/N$ for the compact subgroup $N := \hat{G}/\hat{M}$, we see that the translation action of $\hat{G}$ on $\hat{M}$ is proper, too. Hence, the restriction of $\lambda_\omega$ to $M$ provides a $\hat{G}$-equivariant embedding of $C_0(\hat{M}) \cong C^* (M, \omega)$ into $C^* (G, \omega)$, which proves that the dual action of $\hat{G}$ on $C^* (G, \omega)$ is weakly proper.

Of course one might wonder, whether the converse of this observation is true: Is the dual action of $\hat{G}$ on $C^* (G, \omega)$ weakly proper if and only if the restriction of $\omega$ to $\mathbb{R}^n$ is trivial?

Note that there exist quite interesting twisted group algebras given by such examples. For instance, let $\omega$ be the Heisenberg-cocycle on $\mathbb{R} \times Q$ given by the formula

$$\omega((s, q), (t, r)) = e^{2\pi i sr}.$$  

Then the twisted group algebra $C^* (\mathbb{R} \times Q, \omega)$ is isomorphic to the crossed product $C_0(\mathbb{R} \rtimes Q)$ where $Q$ acts by translation on $\mathbb{R}$. Since this action is minimal (i.e., all orbits are dense), this algebra is simple.

4. Exel-Meyer proper actions and counterexamples

In this section we want to use our characterisation of Rieffel proper actions to show that certain examples of Exel-Meyer proper actions as discussed by Meyer in [10] are actually Rieffel proper. This will provide us with examples in which a given $G$-algebra $(A, \alpha)$ has infinitely many different dense subspaces $R_i \subseteq A$, $i \in I$, such that $\alpha : G \to \text{Aut}(A)$ is Rieffel proper with respect to all $R_i$, as in Proposition 2.5 but with pairwise non-isomorphic generalised fixed-point algebras. As we shall see, such examples can even occur if all such Rieffel proper actions are saturated. In this case all fixed-point algebras have to be Morita-equivalent, since they are Morita equivalent to $A \rtimes_r G$.

We start with a brief introduction to the theory of Exel-Meyer proper actions as defined by Exel and Meyer in [10] and [15,10]. Such actions provide generalisations
of Rieffel proper actions which still allow the construction of generalised fixed-point algebras \( A^G \).

Let \( (B, \beta) \) be a \( G \)-algebra. In what follows we realise the left regular representation \( \lambda^B : C_c(G, B) \to \mathcal{L}(\ell^2(G, B)) \) by the formula

\[
\lambda^B_g(f)(t) := \int_G \Delta(s)^{-1} \beta_{s^{-1}}(\varphi(ts^{-1})) f(s) ds \quad \varphi \in C_c(G, B), f \in \ell^2(G, B).
\]

Recall that the reduced crossed product \( B \rtimes_{\beta, r} G \) can be defined as the closure of \( \lambda^B(C_c(G, B)) \) inside \( \mathcal{L}(\ell^2(G, B)) \). More generally, we say that a continuous function \( \varphi : G \to B \) is a bounded symbol if the integral operator \( \lambda^B_\varphi \) of \( (4.1) \), which makes always sense for \( f \in C_c(G, B) \), extends to an adjointable operator in \( \mathcal{L}(\ell^2(G, B)) \). Such an integral operator is called Laurent operator with symbol \( \varphi \), a terminology introduced in \([10]\). We shall often identify bounded symbol functions \( \varphi \) with the corresponding operator \( \lambda^B_\varphi \).

Assume now that \( (\mathcal{E}, \gamma) \) is a \( G \)-equivariant Hilbert \( B \)-module. Given \( \xi \in \mathcal{E} \), we define linear operators:

\[
|\xi\rangle : C_c(G, B) \to \mathcal{E}, \quad |\xi\rangle f := \int_G \Delta(t)^{-1/2} \gamma_{t^{-1}}(\xi) f(t) dt,
\]

and

\[
\langle \xi | : \mathcal{E} \to C(G, B), \quad \langle \xi | \eta(t) := \Delta(t)^{-1/2} \gamma_{t^{-1}}(\xi) \eta.
\]

We say that \( \xi \) is square integrable if \( |\xi\rangle \) extends to an adjointable operator \( \ell^2(G, B) \to \mathcal{E} \). This is equivalent to saying that the continuous function \( \langle \xi | \eta \rangle \) lies in \( \ell^2(G, B) \); and in this case \( |\xi\rangle \) is automatically the adjoint operator of \( |\xi\rangle \). It is easy to see that \( |\xi\rangle \) and \( \langle \xi | \) are \( G \)-equivariant operators with respect to the given \( G \)-action \( \gamma \) on \( \mathcal{E} \) and the \( \beta \)-compatible \( G \)-action \( (\rho \otimes \beta)(f)(s) := \Delta(t)^{1/2} \beta_{t^{-1}}(f(s)) \) on the Hilbert \( B \)-module \( \ell^2(G, B) \).

The \( G \)-equivariant Hilbert \( B \)-module \( (\mathcal{E}, \gamma) \) is called square integrable if the space \( \mathcal{E}_s \) of square-integrable elements is dense in \( \mathcal{E} \). The theory of square-integrable modules is developed in detail by Meyer in \([15, 16]\). Actually, in the papers \([15, 16]\) the modular function and the inverses do not show up in the definition of \( \langle \xi | \) or \( |\xi\rangle \), i.e., \( \gamma_{t^{-1}}(\xi) \) appears in place of \( \Delta(t)^{-1/2} \gamma_{t^{-1}}(\xi) \) above. The reason is that Meyer uses the left regular representation \( \lambda \) as the \( \lambda \)-equivariant representation of \( G \) on \( \ell^2(G) \), while we use the right regular representation \( \rho \) instead. The above formulas translate into Meyer’s formulas via the unitary intertwiner \( U : \ell^2(G) \to \ell^2(G) ; (U f)(t) := \Delta(t)^{-1/2} f(t^{-1}) \) between \( \lambda \) and \( \rho \). The operators \( |\xi\rangle \circ U \) and \( U \circ \langle \xi | \) are then exactly the operators used by Meyer in \([16]\). Our convention follows the paper \([10]\) by Exel, from which the basic ideas in \([16]\) are built.

A \( G \)-algebra \( (A, \alpha) \), when viewed as a \( G \)-equivariant Hilbert \( A \)-module in the canonical way, is square-integrable if and only if it is integrable in the sense of Definition \([2, 2]\). More generally, it is proved in \([15]\) that a \( G \)-equivariant Hilbert \( B \)-module \( (\mathcal{E}, \gamma) \) is square integrable if and only if the \( G \)-algebra of compact operators \( A = \mathcal{K}(\mathcal{E}) \) with \( G \)-action \( \alpha = \text{Ad} \gamma \) is integrable. Moreover, if \( \xi, \eta \in \mathcal{E}_s \), then the rank-one operator \( |\xi\rangle \langle \eta | \in \mathcal{K}(\mathcal{E}) \) defined by \( |\xi\rangle \langle \eta | \zeta = \langle \xi | \eta \rangle \zeta \in \mathcal{E}_s \) is \( \alpha \)-integrable and

\[
\int_G \alpha_t(|\xi\rangle \langle \eta |) dt = |\xi\rangle \langle \eta |,
\]

where \( |\xi\rangle \langle \eta | \) denotes the composition \( |\xi\rangle \circ \langle \eta | \in \mathcal{L}_A^G(A) = \mathcal{M}(A)^G \).

To see the connection of integrability with Rieffel properness it is important to describe in detail the composition \( \langle \xi | \circ |\eta| \rangle \) for all \( \xi, \eta \in \mathcal{E}_s \), which is a \( G \)-equivariant operator on \( \ell^2(G, B) \), that is, an element of the fixed-point algebra \( \mathcal{M}(B \otimes \mathcal{K}(\ell^2(G)))^G = \mathcal{L}_B^G(\ell^2(G, B)) \). In general, if \( \xi, \eta \in \mathcal{E} \), we define \( \langle \xi | \eta \rangle \) to be the continuous function
t → Δ(t)^{-1/2}⟨ξ | γₜ(η)⟩). We then compute for f ∈ C₀(G, B):

\[ \langle ξ | ℓ | η \rangle(f)|_t = \Delta(t)^{-1/2}⟨γₜ⁻¹(ξ) | γₜ⁻¹(η)⟩ f(s) \]

\[ = \int_G \Delta(ts)^{-1/2}⟨γₜ⁻¹(ξ) | γₜ⁻¹(η)⟩ f(s) \, ds \]

\[ = \int_G Δ(s)^{-1}βₜ⁻¹(Δ(ts^{-1})^{-1/2}⟨ξ | γₜ⁻¹(η)⟩) f(s) \, ds \]

\[ = \int_G Δ(s)^{-1}βₜ⁻¹(⟨⟨ξ | η⟩⟩(ts^{-1})) f(s) \, ds \]

\[ = λ^B_φ(⟨⟨ξ | η⟩⟩(f)) |_t, \]

so that we get the equation \( \langle ξ | η \rangle = \langle ξ | ℓ | η \rangle \) for \( ξ, η ∈ E \). We say that the symbol \( \langle ξ | η \rangle \) is the corresponding Laurent operator \( λ^B_φ(⟨⟨ξ | η⟩⟩) \).

It is easy to see that for every bounded symbol function \( φ ∈ C(G, B) \), \( λ^B_φ \) is always an element of the fixed-point \( C^* \)-subalgebra \( L^G₀(G, B) = \mathcal{M}(B ⊗ K(L^G₀(G, B))) \).

In particular, \( B ⊗_{β, r} G ⊆ \mathcal{M}(B ⊗ K(L^G₀(G, B))) \), where \( G \) acts on \( B ⊗ K(L^G₀(G, B)) \) via \( β ⊗ Ad_p \). But for a bounded symbol \( φ \), the Laurent operator \( λ^B_φ \) need not be in \( B ⊗_{β, r} G \).

The following definition is the main point of the above discussion:

**Definition 4.2 (Exel-Meyer).** We say that a subspace \( R ⊆ E \) is a continuous subspace if \( ⟨⟨R | R⟩⟩ \) is a dense relatively continuous subspace of \( E \).

We say that the action \( (E, γ) \) is an Exel-Meyer proper if there is a dense relatively continuous subspace \( R ⊆ E \).

In particular, if \( (A, α) \) is a \( G \)-algebra, we say that \( α \) is an Exel-Meyer proper if there is a dense relatively continuous subspace \( R ⊆ A \), where we view \( (A, α) \) as a \( G \)-equivariant Hilbert \( A \)-module.

In the above form, these actions were introduced by Meyer in \([16]\), but the essential ideas are already contained in Exel’s paper \([10]\) who defined relative continuity for actions of locally compact abelian groups on \( C^* \)-algebras only. The Exel-Meyer proper actions are, in a sense, the most general proper actions which allow the construction of generalised fixed-point algebras:

**Definition 4.3.** The generalised fixed-point algebra associated to a relatively continuous subspace \( R ⊆ E \) is, by definition, the \( C^* \)-subalgebra \( \text{Fix}(E, R) \) of \( L^G₀(E) = \mathcal{M}(K(E))^G \) generated by the operators \( |ξ⟩⟨η| = \int_G ρ_0^*_s|γ_s(ξ⟩⟨γ_s(η)⟩ \, dt \) with \( ξ, η ∈ R \).

The generalised fixed-point algebra \( \text{Fix}(E, R) \) is always Morita equivalent to an ideal in \( B ⊗_{β, r} G \). The construction of the bimodule \( F(R) \) implementing this equivalence can be performed essentially in the same way as we did for Rieffel proper actions: take \( \hat{R} := R * C_∞(G, B) \) and endow it with the usual right \( C_∞(G, B) \)-convolution action and the inner product \( ⟨⟨.|.|⟩⟩ \) complete it to a right Hilbert \( B ⊗_{β, r} G \)-module \( F(R) \). The algebra of compact operators on \( F(R) \) is then canonically isomorphic to \( \text{Fix}(E, R) \) with left action induced by the left action of \( L(E) \) on \( R \) and the left-inner product \( ⟨ξ, η⟩ → |ξ⟩⟨η| \). The details can be found in \([16]\) §6.

If \( (E, γ) \) is a \( G \)-equivariant Hilbert \( (B, β) \)-module, there is an important connection between relatively continuous dense subsets \( R_E ⊆ E \) and relatively continuous dense subsets \( R_K ⊆ K(E)_{sa} \) given as follows: If \( R_E ⊆ E \) is relatively continuous, then it is shown in \([16]\) Corollary 7.2 that

\[ R_K := \text{span}\{⟨ξ | η⟩ : ξ ∈ R_E, η ∈ E \} \]

is a dense relatively continuous subset of \( K(E)_{sa} \) with respect to the action \( α = Ad γ \) such that the corresponding Hilbert \( K(E) ⊗_{Ad γ, r} G \)-module \( F(R_K) \) satisfies

\[ F(R_K) ≅ F(E) ⊗_{B ⊗_{β, r} G} (E^* ⊗_{r} G). \]
In particular, since $\mathcal{K}(\mathcal{E}^* \rtimes_r G)$ is an ideal in $B \rtimes_r G$, it follows that
\begin{equation}
\mathcal{K}(\mathcal{E})^G := \text{Fix}(\mathcal{K}(\mathcal{E}), \mathcal{R}_K) = \mathcal{K}(\mathcal{F}(\mathcal{R}_E)) = \mathcal{K}(\mathcal{F}(\mathcal{R}_E) \otimes_{B \rtimes_r G} (\mathcal{E}^* \rtimes_r G))
= \mathcal{K}(\mathcal{F}(\mathcal{R}_E)) = \text{Fix}(\mathcal{E}, \mathcal{R}_E).
\end{equation}
Conversely, if $(A, \alpha)$ is any square-integrable $G$-$C^*$-algebra, $\phi : A \to \mathcal{L}(\mathcal{E})$ is a nondegenerate $G$-equivariant $*$-homomorphism, and $\mathcal{R}_A \subseteq A_{sa}$ is a dense relatively continuous subspace of $A$, then it is shown in [13] Corollary 7.1 that $\mathcal{R}_E := \phi(\mathcal{R}_A)\mathcal{E}$ is a dense relatively continuous subspace of $\mathcal{E}_{sa}$ such that
\[ \mathcal{F}(\mathcal{R}_E) \cong \mathcal{F}(\mathcal{R}_A) \otimes_{A_{sa}, G} (\mathcal{E} \rtimes_r G) \]
as Hilbert $B \rtimes_r G$-modules. In particular, if $A = \mathcal{K}(\mathcal{E})$ we get
\[ \text{Fix}(\mathcal{E}, \mathcal{R}_E) = \mathcal{K}(\mathcal{F}(\mathcal{R}_E)) \cong \mathcal{K}(\mathcal{F}(\mathcal{R}_K)) = \text{Fix}(\mathcal{K}(\mathcal{E}), \mathcal{R}_K) = \mathcal{K}(\mathcal{E})^G. \]

We now want to discuss a similar correspondence between subsets $\mathcal{R}_E \subseteq \mathcal{E}$ and $\mathcal{R}_K \subseteq \mathcal{K}(\mathcal{E})$ which induce Rieffel properness as in Proposition 2.5. Motivated by the above discussion on relatively continuous subsets, we introduce the following:

**Definition 4.5.** Let $(\mathcal{E}, \gamma)$ be a $G$-equivariant Hilbert $(B, \beta)$-module. Then a subset $\mathcal{R} \subseteq \mathcal{E}$ is said to be relatively $L^1$ if for each $\xi, \eta \in \mathcal{R}$ the function $\langle \xi | \eta \rangle = \langle s \mapsto \Delta(s)^{-1/2} \langle \xi | \gamma_s(\eta) \rangle \rangle_B$ lies in $L^1_\Delta(G, B)$. Of course, if $(A, \alpha)$ is a $G$-algebra, viewed as a $G$-equivariant Hilbert $(A, \alpha)$-module, then a subset $\mathcal{R} \subseteq A$ is relatively $L^1$ in the sense of the above definition if and only if it satisfies condition (P1) of Proposition 2.5. Hence there exists a dense relatively $L^1$ subspace $\mathcal{R} \subseteq A$ if and only if the action $\alpha : G \to \text{Aut}(A)$ is Rieffel proper. Motivated by Proposition 2.5 we introduce the following:

**Definition 4.6.** Suppose that $(\mathcal{E}, \gamma)$ is a $G$-equivariant Hilbert $(B, \beta)$-module. We say that the action $\gamma : G \to \text{Aut}(\mathcal{E})$ is Rieffel proper if there exists a dense relatively $L^1$-subspace $\mathcal{R} \subseteq \mathcal{E}$. It follows directly from the definition and the fact that $L^1(G, B) \subseteq B \rtimes_r G$ that every dense relatively $L^1$-subspace $\mathcal{R} \subseteq \mathcal{E}$ is also relatively continuous in the sense of Exel-Meyer. Therefore it follows from the results of Meyer in [16] that $\mathcal{R} = \mathcal{R} \rtimes C_c(G, B)$ completes to a Hilbert $B \rtimes_r G$-module $\mathcal{F}(\mathcal{R})$ with respect to the $B \rtimes_r G$-valued inner product
\[ \langle \xi | \eta \rangle = \left( s \mapsto \Delta(s)^{-1/2} \langle \xi | \gamma_s(\eta) \rangle \right) \in L^1_\Delta(G, B) \subseteq B \rtimes_r G. \]

Since $C_c(G, B)$ is dense in $L^1_\Delta(G, B) \subseteq B \rtimes_r G$, it follows that every element in $\mathcal{R} \rtimes L^1_\Delta(G, B)$ can be approximated by elements in $\mathcal{R} \rtimes C_c(G, B)$ in the norm induced by the $B \rtimes_r G$-valued inner product $\langle \cdot | \cdot \rangle$. Hence, if $\mathcal{R}_A \subseteq A$ is a dense relatively $L^1$-subspace of a $G$-$C^*$-algebra $(A, \alpha)$, then $\mathcal{F}(\mathcal{R}_A)$ coincides with the module as discussed preceding Proposition 2.7. In particular, the corresponding fixed-point algebras coincide.

**Lemma 4.7.** Suppose that $(\mathcal{E}, \gamma)$ is a $G$-equivariant Hilbert $(B, \beta)$-module and that $\mathcal{R}_E \subseteq \mathcal{E}$ is a dense relatively $L^1$-subspace of $\mathcal{E}$. Then
\[ \mathcal{R}_K := \text{span}\{ [\xi | \eta] : \xi \in \mathcal{R}_E, \eta \in \mathcal{E} \} \]
is a dense relatively $L^1$-subspace of $\mathcal{K}(\mathcal{E})$ such that
\[ \mathcal{F}(\mathcal{R}_K) \cong \mathcal{F}(\mathcal{R}_E) \otimes_{B \rtimes_r G} (\mathcal{E}^* \rtimes_r G). \]
Conversely, if $(A, \alpha)$ is a $G$-$C^*$-algebra such that there exists a nondegenerate $G$-equivariant $*$-homomorphism $\phi : A \to \mathcal{L}(\mathcal{E})$ and if $\mathcal{R}_A$ is a dense relatively
$L^1$-subspace of $A$, then $\mathcal{R}_E = \phi(\mathcal{R}_A)E$ is a dense relatively $L^1$-subspace of $E$ such that

$$F(\mathcal{R}_E) \cong F(\mathcal{R}_A) \otimes_{A \rtimes_r G} (E \rtimes_r G).$$

Proof. For the proof we only need to check the $L^1$ conditions for $\mathcal{R}_K$ and $\mathcal{R}_E$, respectively, since everything else will follow from the corresponding results for Exel-Meyer proper actions as discussed above.

So suppose that $\mathcal{R}_E \subseteq E$ is a relatively $L^1$-subspace of $E$. Recall that $|\xi\rangle\langle\eta| \in K(E)$ is the operator defined by

$$|\xi\rangle\langle\eta| \xi = \xi \cdot \langle\eta| \zeta_B$$

for all $\zeta \in E$. Then a short computation shows that for $\xi, \xi', \eta, \eta' \in E$ we get the equation

$$|\xi\rangle\langle\eta| \circ |\xi'\rangle\langle\eta'| = |\xi \cdot \langle\eta| \xi'\rangle_B\rangle\langle\eta'|.$$

Using this we get for all $\xi, \xi' \in \mathcal{R}_E$ and $\eta, \eta' \in E$ that

$$(|\xi\rangle\langle\eta|)^* \circ \operatorname{Ad}\gamma_s(|\xi'\rangle\langle\eta'|) = |\eta\rangle\langle\xi \circ |\gamma_s(\xi')\rangle(\gamma_s(\eta'))$$

$$= |\eta \cdot (\xi \circ |\xi'|) B\rangle\langle\eta'|,$$

from which it follows that

$$\|(|\xi\rangle\langle\eta|)^* \circ \operatorname{Ad}\gamma_s(|\xi'\rangle\langle\eta'|)\| \leq \|\xi\gamma_s(\xi')\| \|\eta\| \|\eta'\|.$$
the $C(T^k)$-valued inner product on the subspace $\hat{\mathcal{R}} = \{ \hat{\xi} : \xi \in \mathcal{R} \} \subset L^2(T^k)^n$ with inner product

$$\langle \hat{\xi} | \hat{\eta} \rangle_{C(T^k)}(z) = \sum_{i=1}^{n} \bar{\xi}_i \cdot \bar{\eta}_i(z).$$

The Plancherel isomorphism $\ell^2(\mathbb{Z})^n \cong L^2(T^k)^n$ intertwines the right regular representation $\rho$ of $\mathbb{Z}^k$ on $\ell^2(\mathbb{Z}^k)$ with the unitary representation $\hat{\rho}$ given by

$$(\hat{\rho}_m \xi)(z) = z^{-m} \xi(z) \quad \forall z \in T^k, m \in \mathbb{Z}^k,$$

where $z^{-m} := z_1^{-m_1} \cdots z_k^{-m_k} \in T$. The dense relatively continuous subspaces $\hat{\mathcal{R}} \subseteq L^2(T^k)^n$ with respect to the unitary representation $\hat{\rho}^n$ have been studied in detail by Meyer in [16 §8] and by Buss and Meyer in [7]. In particular, we are interested in the following two special examples:

**Example 4.8.** Consider the case $n = 1$. Let $S \subseteq T^k$ be an open dense subspace of $T^k$ with full Haar measure. Then we get the following chain of dense subsets in $L^2(T^k) \cong \ell^2(\mathbb{Z}^k)$:

$$\hat{\mathcal{R}}_S = C_c^\infty(S) \subseteq C_c(S) \subseteq L^2(S) = L^2(T^k),$$

where $C_c^\infty(S)$ denotes the set smooth functions with compact supports on $S$. Then the $C(T^k)$-valued inner products $\langle \xi | \eta \rangle_{C(T^k)} = \hat{\xi} \cdot \eta$ all lie in

$$C_c^\infty(S) \subseteq I_S := C_0(S) \subseteq C(T^k).$$

Since the inverse Fourier-transform of any smooth function on $T^k$ lies in $\ell^1(\mathbb{Z}^k)$ we see that the preimage $\mathcal{R}_S$ of $\hat{\mathcal{R}}_S$ under the Fourier transform is a dense relatively $L^1$-subspace of $\ell^2(\mathbb{Z}^k)$. As in [16 §8] one checks that the module $\mathcal{F}(\hat{\mathcal{R}}_S)$ is isomorphic to the standard $C_0(S) - C_0(S)$ equivalence bimodule $C_0(S)$, thus the generalized fixed-point algebra $\mathcal{K}(\ell^2(\mathbb{Z}^k))^\mathbb{Z}^k, \text{Ad}_\rho = \text{Fix}(\ell^2(\mathbb{Z}^k), \mathcal{R}_S)$ is also isomorphic to $C_0(S)$. Since there exist infinitely many non-homeomorphic open dense subsets $S \subseteq T^k$, there exist infinitely many non-isomorphic generalised fixed-point algebras for the Rieffel proper action $\text{Ad}_\rho : \mathbb{Z}^k \to \text{Aut}(\mathcal{K}(\ell^2(\mathbb{Z}^k)))$.

One might observe that in the above example only the case $S = T^k$ provides a structure of a saturated Rieffel proper action in which the corresponding Hilbert $C^*(\mathbb{Z}^k)$-module $\mathcal{F}(\mathcal{R}_S)$ is full. But the following slight alteration of another example given by Meyer in [16 §8] yield examples of different saturated Rieffel proper structures with non-isomorphic fixed-point algebras:

**Example 4.9.** We are now looking at structures $\mathcal{R} \subseteq \ell^2(\mathbb{Z}^k)^n$. Again we dualise in order to consider subspaces $\hat{\mathcal{R}} \subseteq L^2(\mathbb{Z}^k)^n$. Suppose that $p : \mathcal{V} \to T^k$ is an $n$-dimensional complex hermitian vector bundle over $T^k$. Then the Hilbert space $L^2(T^k, \mathcal{V})$ of $L^2$-sections of $\mathcal{V}$ is isomorphic to $L^2(\mathbb{Z}^k)^n$. The easiest way to see this is to choose a partition $\{ A_i : 1 \leq i \leq m \}$ of $T^k$ with measurable sets $A_i \subseteq T^k$ such that $\mathcal{V}|_{A_i} \cong A_i \times \mathbb{C}^n$. Then both spaces are isomorphic to $\oplus_{i=1}^{m} L^2(A_i)^n$. As pointed out in [16 p. 190], the subspace $\hat{\mathcal{R}}_\mathcal{V} := C(T^k, \mathcal{V}) \subseteq L^2(T^k, \mathcal{V})$ of continuous sections of the vector bundle $\mathcal{V}$ is a dense relatively continuous subset of $L^2(T^k, \mathcal{V}) \cong L^2(\mathbb{Z}^k)^n$ with full $C(T^k) \cong C^*(\mathbb{Z}^k)$-valued inner product, which makes it into a $C(T^k, \text{End}(\mathcal{V})) - C(T^k)$ equivalence bimodule. Hence the inverse image $\mathcal{R}_\mathcal{V}$ of $\hat{\mathcal{R}}_\mathcal{V}$ under the Plancherel isomorphism is a dense relatively continuous subset of $\ell^2(\mathbb{Z}^k)^n$ with corresponding generalised fixed-point algebra

$$\text{Fix}(\ell^2(\mathbb{Z}^k)^n, \mathcal{R}_\mathcal{V}) \cong C(T^k, \text{End}(\mathcal{V})).$$

Now, if $p : \mathcal{V} \to T^k$ is a smooth vector bundle, we can look at the subspace

$$\hat{\mathcal{R}}^\chi_\mathcal{V} := \{ \xi \in \ell^2(\mathbb{Z}^k)^n : \hat{\xi} \in C^\infty(T^k, \mathcal{V}) \}.$$
Then the $C(\mathbb{T}^k)$-valued inner product $\langle \xi | \eta \rangle_{C(\mathbb{T}^k)}$ for $\xi, \eta \in R_\mathbb{N}$ lies in $C^\infty(\mathbb{T}^k)$ and therefore $\langle \xi | \eta \rangle = F^{-1}(\langle \hat{\xi} | \hat{\eta} \rangle_{C(\mathbb{T}^k)}) \in \ell^1(\mathbb{Z}^k)$, where $F^{-1}$ denotes inverse Fourier transform. Hence $R_\mathbb{N}$ is a dense relatively $L^1$-subspace of $\ell^1(\mathbb{Z}^k)$. Since every continuous section $\xi : \mathbb{T}^k \to V$ can be approximated by smooth sections with respect to the $C(\mathbb{T}^k)$-valued inner product, the module $F(R_\mathbb{N})$ coincides with $F(R_V)$, hence the corresponding generalised fixed-point algebra is also $C(\mathbb{T}^k, End(V))$. In particular, in case of the trivial bundle $V = \mathbb{T}^k \times \mathbb{C}^n$ the fixed-point algebra will be $C(\mathbb{T}^k, M_n(\mathbb{C}))$.

Thus, in order to find different structures for saturated Rieffel properness of the action $\text{Adp}^n : \mathbb{Z}^k \to \text{Aut}(K(\ell^2(\mathbb{Z}^k)^n))$ with non-isomorphic fixed-point algebras, it suffices to find smooth $n$-dimensional vector bundles $\mathcal{V}$ over $\mathbb{T}^k$ such that $C(\mathbb{T}^k, End(\mathcal{V}))$ is not isomorphic to $C(\mathbb{T}^k, M_n(\mathbb{C}))$. As pointed out on the bottom of [16] p. 190, if $k = n = 2$ and if $L_1$ is a smooth realisation of the line bundle on $\mathbb{T}^2$ corresponding to the generator of $H^2(\mathbb{T}^2, \mathbb{Z})$, which is given by $\langle T \times [0, 1] \rangle \subseteq \mathbb{C}$ at the endpoints with respect to the smooth function

$$T \times \{0\} \subseteq \mathbb{C}$$

$$\mathcal{V} \times [0, 1] \times \mathbb{C} : (z, 0, v) \mapsto (z, 1, zv),$$

then for $\mathcal{V} = \mathcal{V} \oplus L_1$ we have $C(\mathbb{T}^n, End(\mathcal{V})) \not\cong C(\mathbb{T}^n, M_2(\mathbb{C}))$. More generally, if we let $L_n$ denote the line bundle over $\mathbb{T}^2$ given by gluing $\langle T \times [0, 1] \rangle \subseteq \mathbb{C}$ at the endpoints with respect to the smooth function $(z, 0, v) \mapsto (z, 1, z^n v)$, for $n \in \mathbb{Z}$, and putting $V_n = \mathcal{V} \oplus L_n$, then similar arguments as used by Meyer show that the corresponding generalised fixed-point algebras $C(\mathbb{T}^2, End(V_n))$ are pairwise non-isomorphic. This yields infinitely many relatively $L^1$-subspaces $R_m \subseteq \ell^1(\mathbb{Z}^2)^2$ for the $\mathbb{Z}^2$-algebra $K(\ell^2(\mathbb{Z}^2)^2)$, $\text{Adp}^2$ such that the corresponding fixed-point algebras are pairwise non-isomorphic.
