Sophia-Antipolis, March 2017

Abstract

In this talk, we show that if the non Gaussian part of the cumulants of a random matrix model obey some scaling bounds in the size of the matrix, then Wigner’s semicircle law holds. This result is derived using the replica technique and an analogue of the renormalisation group equation for the replica effective action.

1 Introduction

Random matrix theory (see the classical text [1]) first appeared in physics in Wigner’s work on the level spacing in large nuclei. Since then, it has proved to have multiple applications to physics and other branches of science, see for instance [2]. Most of these applications rely on the universal behaviour of some of the observables for matrices of large size. A simple example is Wigner’s semicircle law for the eigenvalue density that holds in the large $N$ limit for matrices whose entries are independent and identically distributed.

Understanding the universal behaviour of eigenvalue distributions and correlations ranks among the major problems in random matrix theory. In this respect, the renormalisation group turns out to be a powerful technique. Introduced in the context of critical phenomena in statistical mechanics by K. Wilson to account for the universality of critical exponents, the latter has also proved to be useful in understanding probability

theory. For instance it leads to an insightful proof of the central limit theorem, see the review by G. Jona-Lasinio \[3\] and references therein.

The renormalisation group has been used to derive the semicircle law for random matrices in the pioneering work of E. Brézin and A. Zee \[4\]. In the latter approach, the renormalisation group transformation consists in integrating over the last line and column of a matrix of size $N+1$ to reduce it to a size $N$ matrix. This leads to a differential equation for the resolvent $G(z) = 1/N\langle \text{Tr}(z - M)^{-1} \rangle$ in the large $N$ limit whose solution yields the semicircle law.

In this talk, we follow a different route: We first express the resolvent as an integral over replicas and introduce a differential equation for the replica effective action. This differential equation is a very simple analogue of Polchinski’s exact renormalisation group equation \[5\]. It is used to derive inductive bounds on the various terms, ensuring that the semicircle law is obeyed provided the cumulants of the original matrix model fulfil some simple scaling bounds in the large $N$ limit.

This talk is based on some work in collaboration with A. Tanasa and D.L. Vu in which we extend Wigner’s law to random matrices whose entries fail to be independent \[6\], to which we refer for further details. There have been other works on such an extension, see \[7\], \[8\] and \[9\].

\section{What are random matrices?}

A random matrix is a probability law on a space of matrices, usually given by the joint probability density on its entries,

$$\rho(M) = \rho(M_{11}, M_{12}, \ldots)$$

Thus a random matrix of size $N$ is defined as a collection of $N^2$ random variables. However, there is a much richer structure than this, relying notably on the spectral properties of the matrices.

Here we restrict our attention to a single random matrix. Note that it is also possible to consider several random matrices, in which case the non commutative nature of matrix multiplication plays a fundamental role, leading to the theory of non commutative probabilities.

There are two important classes of probability laws on matrices.

- **Wigner ensemble**: The entries are all independent variables,

  $$\rho(M) = \prod_{i,j} \rho_{ij}(M_{ij}),$$

  up to the Hermitian condition $M_{ij} = M_{ji}$.

- **Unitary ensemble**: The probability law is invariant under unitary transformations

  $$\rho(UMU^\dagger) = \rho(M),$$

  for any unitary matrix $U \in U(N)$. 

2
The only probability laws that belong to both classes are the Gaußian ones
\[ \rho(M) \propto \exp \left( -\frac{1}{2\sigma^2} \text{Tr}(M)^2 \right), \tag{4} \]
up to a shift of \( M \) by a fixed scalar matrix.

The main objects of interest are the expectation values of observables, defined as
\[ \langle O \rangle = \int dM \rho(M) O(M). \tag{5} \]
Among the observables, the spectral observables defined as symmetric functions of the eigenvalues of \( M \), play a crucial role in many applications. This is essentially due to their universal behaviour: In the large \( N \) limit, for some matrix ensembles and in particular regimes, the expectation values of specific spectral observables do not depend on the details of the probability law \( \rho(M) \).

Universality is at the root of the numerous applications to physics and other sciences, since the results we obtain are largely model independent. Among the applications to physics, let us quote the statistics of energy levels in heavy nuclei, disordered mesoscopic systems, quantum chaos, chiral Dirac operators, ...

### 3 Wigner’s semicircle law

In this talk, we focus on the eigenvalue density, defined as
\[ \rho(\lambda) = \frac{1}{N} \left\langle \sum_{1 \leq i \leq N} \delta \left[ \lambda - \lambda_i \left( \frac{M}{\sqrt{N}} \right) \right] \right\rangle. \tag{6} \]
In particular, a universal behaviour is expected in the large \( N \) limit for some ensembles.

For a Gaußian random Hermitian matrix \( \rho(M) \propto \exp -\frac{1}{2\sigma^2} \text{Tr}(M)^2 \), the eigenvalue density obeys Wigner semicircle law,
\[ \lim_{N \to \infty} \int d\lambda \lambda^k \rho(\lambda) = \begin{cases} \frac{1}{2\pi\sigma^2} \int_{-2\sigma}^{2\sigma} d\lambda \lambda^k \sqrt{4\sigma^2 - \lambda^2} & \text{if } k \text{ is even}, \\ 0 & \text{if } k \text{ is odd}. \end{cases} \tag{7} \]
Empirically, \( \rho(\lambda) \) may be determined by plotting the histogram of eigenvalue of a matrix taken at random with a given probability law, see figure [1].

The derivation of Wigner’s semicircle in the large \( N \) limit is based on the resolvent (also known as the Green function)
\[ G(z) = \lim_{N \to +\infty} \frac{1}{N} \left\langle \text{Tr} \left( z - \frac{M}{\sqrt{N}} \right)^{-1} \right\rangle = \frac{z}{2\sigma^2} \left( 1 - \sqrt{1 - \frac{4\sigma^2}{z^2}} \right), \tag{8} \]
Then, the density of eigenvalues is recovered as
\[ \rho(\lambda) = \frac{G(\lambda - i0^+) - G(\lambda + i0^+)}{2\pi i}, \tag{9} \]
where we have used the relation
\[
\frac{1}{x \pm i0^+} = \text{p.v.} \frac{1}{x} \mp 2i\pi \delta(x).
\]  
(10)

In the large \( N \) limit, for the Gaußian model, the resolvent obeys the self consistency equation (also known as the Schwinger-Dyson equation), see for instance [10], section VII.4,
\[
G(z) = \sum_{k=0}^{\infty} \frac{\sigma G(z)}{z^{k+1}} = \frac{1}{z - \sigma G(z)}.
\]  
(11)

Its solution that behave as \( 1/z \) for large \( z \) is
\[
G(z) = \frac{x}{2\sigma^2} \left( 1 - \sqrt{1 - \frac{4\sigma^2}{x^2}} \right).
\]  
(12)

Taking the cut of the square root on the negative real axis, we obtain the Wigner semicircle law \( \text{(7)} \) in the large \( N \) limit.

The semicircle law is not limited to the Gaußian case, it also holds for Wigner matrices in the large \( N \) limit. A random Hermitian \( N \times N \) matrix is a Wigner matrix if

- real and imaginary parts of upper diagonal elements are independent and identically distributed (i.i.d.) with mean 0 and variance \( \sigma \); 
- diagonal elements are i.i.d. with finite mean and variance and independent of the off diagonal ones.

Then, in the limit \( N \to +\infty \), the eigenvalue distribution of \( \frac{M}{\sqrt{N}} \) is the semicircle law \( \text{(7)} \).

The original proof is of combinatorial nature and involves the expectation of the moments
\[
\lim_{N \to +\infty} \frac{1}{N^{k/2}} \mathbb{E} \left( \text{Tr}(M^k) \right) = \begin{cases} \frac{(2l)!}{(2l)^{2l+1}(l+1)!} & \text{for } k = 2l \text{ even} \\ 0 & \text{for } k \text{ odd} \end{cases}
\]  
(13)
To derive this result, the idea is to first factorise $\rho$ for a Wigner ensemble as

$$\rho(M) = \prod_i \rho'(M_{ii}) \prod_{i<j} \rho''(\text{Re } M_{ij}) \rho''(\text{Im } M_{ij}),$$

(14)

where $\rho'$ is the common probability density of the real diagonal terms and $\rho''$ the common probability density of the real and imaginary parts of the off diagonal terms.

Then, we expand the trace and integrate over the independent real variables $M_{ii}$, $\text{Re } M_{ij}$ and $\text{Im } M_{ij}$. The power of $N$ in the expectation of a given moment arises from the denominator $\frac{1}{N^{l/2+1}}$ and from the number of independent indices in the summations. In the large $N$ limit, the only configurations that survive are counted by Catalan numbers, $C_l = \frac{(2l)!}{(l!)^2(l+1)}$. Since the latter also appear in the following Taylor expansion

$$z^2 \sigma^2 \left(1 - \sqrt{1 - 4\sigma^2 z^2}\right) = \sum_{l \geq 0} \frac{(2l)!}{(l!)^2(l+1)} \frac{\sigma^{2l}}{z^{2l+1}},$$

(15)

we conclude that

$$G(z) = \lim_{N \to +\infty} \frac{1}{N} \left< \text{Tr} \left(z - \frac{M}{\sqrt{N}}\right)^{-1}\right>$$

(16)

$$= \lim_{N \to +\infty} \sum_{k=0}^{\infty} \frac{1}{z^{k+1}} \frac{1}{N^{k/2+1}} \left< \text{Tr} (M^k)\right>$$

(17)

$$= \frac{z}{2\sigma^2} \left(1 - \sqrt{1 - 4\sigma^2 z^2}\right).$$

(18)

This is the form of the resolvent that leads to Wigner's semicircle law. Here, we see universality at work: In the large $N$ limit, the eigenvalue density is given by the semicircle law, whatever the probability densities $\rho'$ and $\rho''$ are. However, this result relies on the independence of the matrix elements. In the next section, we will extend it to matrices whose entries are not necessary independent.

### 4 Wigner’s law beyond Wigner ensembles

Let us introduce the cumulants, defined through their generating function

$$\langle M_{i_1 j_1} \cdots M_{i_k j_k} \rangle_c = \frac{\partial}{\partial J_{j_1 i_1}} \cdots \frac{\partial}{\partial J_{j_k i_k}} \log \left< \exp \text{Tr}(M J) \right> \bigg|_{J=0}.$$  

(19)

In the physics terminology, these are the connected correlation functions. In particular, the Gaussian cumulants vanish beyond the quadratic term

$$\rho(M) \propto \exp -\frac{1}{2\sigma^2} \text{Tr}(M^2) \Rightarrow \left\{ \begin{array}{ll} \langle M_{ij} M_{kl} \rangle_c = \sigma^2 \delta_{il} \delta_{jk} \\ \text{vanish otherwise} \end{array} \right..$$  

(20)

Therefore, cumulants of degree higher than 2 are a measure of the deviation from the Gaussian case.

Turning back to the general case, for each cumulant we construct an oriented graph as follows (see figure 2 for some examples):
• vertices are distinct matrix indices in the cumulant,
• there is an edge from $i$ to $j$ for every $M_{ij}$.

$$\langle (M_{ij})^2 M_{jk} M_{kl} \rangle_c$$

$$\langle M_{ij} M_{ji} \rangle_c$$

Figure 2: Examples of graph associated to cumulants

Since non quadratic cumulants measure deviations from the Gaussian case, if the perturbation is small it is reasonable to expect that the semi-circle law is still obeyed.

To state this result, recall that an oriented graph is Eulerian if every vertex has an equal number of incoming and outgoing edges. Equivalently, it means that every connected component admits an Eulerian cycle, i.e. an oriented cycle that passes through all edges, respecting the orientation. Furthermore, let us denote $v(G)$, $e(G)$, $c(G)$ the number of vertices, edges and connected components of $G$.

**Theorem 1** (Wigner’s law for matrices with dependent entries). Let $\rho_N$ be a probability law on the space of Hermitian $N \times N$ matrices $M$ such that its cumulants can be decomposed as $C_G = C'_G + C''_G$, with $C'_G$ a Gaussian cumulant and $C''_G$ a perturbation such that, uniformly in the vertex indices $i_1, \ldots, i_{v(G)}$ (i.e. all constants involved should not depend on these indices),

$• \lim_{N \to \infty} N^{v(G)-c(G)-e(G)/2} C''_G(i_1, \ldots, i_{v(G)}) = 0$ if $G$ is Eulerian,
$• N^{v(G)-e(G)-c(G)/2} C''_G(i_1, \ldots, i_{v(G)})$ bounded if $G$ is not Eulerian.

Then, the moments of the eigenvalue distribution of the matrix $\frac{M}{\sqrt{N}}$ converge towards the moments of the semicircle law, with $\sigma$ given by the Gaussian cumulant $\langle M_{ij} M_{kl} \rangle_c = \sigma^2 \delta_{il} \delta_{jk}$,

$$\lim_{N \to \infty} \int_{\mathbb{R}} d\lambda \lambda^k \rho_N(\lambda) = \begin{cases} \frac{1}{2\pi\sigma^{k+2}} \int_{-2\sigma}^{2\sigma} d\lambda \lambda^k \sqrt{4\sigma^2 - \lambda^2} & \text{if } k \text{ is even,} \\ 0 & \text{if } k \text{ is odd.} \end{cases}$$

(21)

For instance, for the graph $\begin{array}{c} \cdot \\ \cdot \end{array}$, which is not Eulerian, with $v = 3$, $e = 4$ and $c = 2$, the cumulant should obey

$$\frac{1}{N} | \langle (M_{ij})^2 M_{jk} M_{kl} \rangle_c | \leq K,$$

(22)

with $K$ a constant that does not depend on the indices $i$, $j$, $k$ and $l$. On the other hand, for the graph $\begin{array}{c} \cdot \\ \cdot \end{array}$, which is Eulerian, with $v = 2$, $e = 4$ and $c = 1$, we impose

$$\lim_{N \to \infty} \frac{1}{N} | \langle (M_{ij})^2 M_{ji} \rangle_c | = 0,$$

(23)
uniformly in $i$ and $j$.

As an illustration, we recover the case of Wigner matrices (with finite moments). Indeed,

- there is no graph with $v \geq 3$ (independence of off diagonal matrix elements);
- for $v = 1$ and $v = 2, e \geq 3$, bounds are satisfied because of $1/N\epsilon/2$ and all moments are assumed to be finite;
- $C_{\square,\square}(i, j) = \langle M_{ij} \rangle_c = \langle M_{ij} \rangle = 0$ (off diagonal elements have mean value 0);
- $C_{\square,\square,\square}(i, j) = \langle M_{ii} M_{jj} \rangle_c = \langle M_{ii} M_{jj} \rangle - \langle M_{ii} \rangle \langle M_{jj} \rangle = 0$ (independence of diagonal elements);
- $C_{\square,\square}(i, j) = \langle M_{ii} M_{jj} \rangle_c = \langle M_{ii} M_{jj} \rangle - \langle M_{ii} \rangle \langle M_{jj} \rangle = 0$ (independence of diagonal and off diagonal elements);
- $C_{\square,\square,\square}(i, j) = \langle (\text{Re} M_{ij})^2 - (\text{Im} M_{ij})^2 \rangle + 2i \langle \text{Re} M_{ij} \text{Im} M_{ij} \rangle = 0$ (independence of real and imaginary parts and equality of their distributions with mean value 0);
- $C_{\square,\square} = \sigma^2$ is the Gaußian cumulant leading to the semicircle law.

The case of unitarily invariant matrices is critical since the bounds are saturated, see [6]. This is consistent since we known the semicircle law is not obeyed by unitary non Gaußian ensembles [13].

It is possible to give a combinatorial proof of this result based on the relation between moments and cumulants,

$$\langle M_{i_1 j_1} \cdots M_{i_k j_k} \rangle = \sum_{I_1, \ldots, I_p \text{ partition of } \{(i_1, j_1), \ldots, (i_k, j_k)\}} \langle \prod_{i j \in I_1} M_{i j} \rangle_c \cdots \langle \prod_{i j \in I_p} M_{i j} \rangle_c \quad \text{(24)}$$

In the moment method, we have to estimate

$$\frac{1}{N^{k/2+1}} \langle \text{Tr}(M^k) \rangle = \frac{1}{N^{k/2+1}} \sum_{1 \leq i_1, \ldots, i_k \leq N} \langle M_{i_1 i_2} \cdots M_{i_k i_1} \rangle. \quad \text{(25)}$$

Then, we express the moments in (25) in terms of cumulants using (24) and represent each cumulant as a graph. Because of the trace, one has to draw Eulerian cycles on the graphs after some vertex identifications. Then, the scaling bounds on the cumulants can be used to show that only Gaussian terms survive.

5 Proof based on the replica effective action

Let us give a renormalisation group proof of this result based on the replica effective action. The use of replicas in random matrix theory is a classical
subject, see for instance [11] or [12]. To begin with, let us note that

$$\text{Tr} \left( z - \frac{M}{\sqrt{N}} \right)^{-1} = \frac{\partial}{\partial z} \log \det \left( z - \frac{M}{\sqrt{N}} \right)$$  \tag{26}

It is convenient to express the logarithm using the replica method. First observe that

$$\log(A) = \lim_{n \to 0} A^n - 1 \over n.$$  \tag{27}

Then, we express the $n^{th}$ power of the determinant as a Gaussian integral over $n$ replicas of a complex vector of size $N$ (with a factor of $\pi n N$ included in the measure),

$$\frac{1}{\det^n(z-M)} = \int dX \exp \left\{ -\text{Tr}(X^\dagger(z-M)X) \right\}$$  \tag{28}

which fit into a $N \times n$ complex matrix $X = (X_{i,a})_{1 \leq i \leq N, 1 \leq a \leq n}$.

The limit $n \to 0$ may be worrisome, its meaning is as follows. Because of $U(n)$ invariance, any perturbative result in powers of $1/z$ is a polynomial in $n$, from which we retain only the linear term. Of course, this may not hold beyond perturbation theory, where replica symmetry breaking can occur.

After averaging over $M$ with the random matrix density $\rho(M)$, we obtain the following expression for the resolvent,

$$G(z) = -\frac{1}{N} \frac{\partial}{\partial z} \left[ \int dX \exp \left\{ -\text{Tr}(X^\dagger X) + V_0(X) \right\} \right] \text{order 1 in } n,$$  \tag{29}

where the replica potential is

$$V_0(X) = \log \left\langle \exp \text{Tr} \left( X^\dagger M \frac{1}{\sqrt{N}} X \right) \right\rangle.$$  \tag{30}

Because of the logarithm, the potential involves the cumulants and can be expanded over graphs as

$$V_0(X) = \frac{1}{|\text{Aut}(G)| N^{\text{edges}}} \sum_{G} \sum_{1 \leq i_1 < \ldots < i_{v(G)} \leq N} C_G(i_1, \ldots, i_{v(G)}) \prod_{e \text{ edge}} (X X^\dagger)_{s(e) t(e)} \text{,}$$  \tag{31}

where $s(e)$ is the source of edge $e$ and $t(e)$ its target.

Let us introduce a replica effective action, obtained by a partial integration

$$V(t, X) = \log \int dY \exp \left\{ -\frac{\text{Tr}(Y^\dagger Y)}{t} + V_0(X + Y) \right\} - Nn \log t.$$  \tag{32}

The parameter $t$ ranges between 0 (where we have no integration, $V(t = 0, X) = V_0(X)$) and $t = 1/z$. 

8
The effective potential obeys a semi-group property that follows from Gaussian convolution (see for instance [14], section A10.1),

\[ V(t + s, X) = \log \int dY \exp \left\{-\frac{\text{Tr}(Y^\dagger Y)}{s} + V(t, X + Y)\right\} - N_n \log s. \] (33)

For small \( s = dt \), it translates into the following renormalisation group equation, which is a simple version of Polchinski’s exact renormalisation group equation [5],

\[ \frac{\partial V(t, X)}{\partial t} = \sum_{i,a} \left( \frac{\partial^2 V(s, X)}{\partial X_{i,a} \partial X_{i,a}} + \frac{\partial V(s, X)}{\partial X_{i,a}} \frac{\partial V(s, X)}{\partial X_{i,a}} \right). \] (34)

The first term on the RHS is referred to as the loop term, since it creates a new loop in the Feynman graph expansion of the effective action while the second inserts a one particle reducible line and is referred as the tree term, see figure 3.

\[ \frac{\partial}{\partial t} \quad = \quad \quad \quad + \quad \quad \]

Figure 3: Graphical interpretation of the renormalisation group equation

Taking into account the boundary condition \( V(t = 0, X) = V_0(X) \), it is convenient to write (34) in integral form

\[ V(t, X) = V_0(X) + \int_0^t ds \sum_{i,a} \left( \frac{\partial^2 V(s, X)}{\partial X_{i,a} \partial X_{i,a}} + \frac{\partial V(s, X)}{\partial X_{i,a}} \frac{\partial V(s, X)}{\partial X_{i,a}} \right). \] (35)

This allows us to derive inductive bounds in powers of \( t = 1/z \).

From a physical point of view, we evaluate the effective potential by a large succession of small partial integrations, with a total weight given by \( t \). Let us stress that in our context this differential equation is merely a tool to control the \( t \) dependence of the effective action after integrating with a \( t \) dependent propagator.

The effective potential also admits an expansion over graphs,

\[ V(t, X) = \sum_{\text{oriented graph}} \frac{1}{|\text{Aut}(G)| N^{(G)/2}} \sum_{1 \leq i_1 \ldots i_{\nu(G)} \leq N \text{ all different}} C_G(t; i_1, \ldots, i_{\nu(G)}) \prod_{\epsilon \text{ edge}} (XX^\dagger)_{i_{\epsilon}(i_{\epsilon}^\dagger)}^{i_{\epsilon}(i_{\epsilon}^\dagger)}. \] (36)

This leads to a graphical interpretation of the action of the two differential operators in the renormalisation group equation, see figure 4. Indeed, in the expansion (36), an edge joining a vertex carrying label \( i \) to a vertex carrying \( j \) is equipped with a factor \( \sum_a X_{i,a} X_{j,a} \), with \( a \) a replica.
index. Then, the differential operator $\frac{\partial}{\partial X_{i,a}}$ (resp. $\frac{\partial}{\partial X_{j,a}}$) removes the outgoing (resp. incoming) half edge. Finally, the remaining half edges are reattached and the vertices identified to yield a new graph on the RHS of (35), with one less edge. These operations are performed on the same graph for the loop term and on distinct ones for the tree term.

\[
\frac{\partial^2 V}{\partial X_{i,a} \partial X_{i,a}} : \quad \begin{array}{c}
\begin{array}{c}
\text{G}_1
\end{array}
\end{array} \rightarrow \begin{array}{c}
\begin{array}{c}
\text{G}_2
\end{array}
\end{array}
\]

\[
\frac{\partial V}{\partial X_{i,a}} \frac{\partial V}{\partial X_{j,a}} : \quad \begin{array}{c}
\begin{array}{c}
\text{G}_1
\end{array}
\end{array} \rightarrow \begin{array}{c}
\begin{array}{c}
\text{G}_2 = \text{G}_3
\end{array}
\end{array}
\]

Figure 4: Action of the differential operators on the vertices of the effective action

Let us decompose the effective cumulants appearing in (36) into Gaussian ones and perturbations, and expand both in a power series in $t = 1/z$,

\[
C_G(t) = \sum_{k=0}^{\infty} t^k \left[ C_G^{(k)} + C_G^{(k)} \right].
\]

(37)

The Gaussian terms are those that are constructed using only the Gaussian term in the initial potential $V_0(X)$. Even if $V_0(X)$ is quartic in $X$, this does not hold for the Gaussian part of $V_t(X)$, that contains terms of all orders. The perturbation collects all the remaining terms, they contain at least one non-Gaussian perturbation from $V_0(X)$.

The renormalisation group equation (35) allows us to prove inductively on $k$ that the perturbations $C_G^{(k)}$ obey the same scaling bound imposed on $C_G^{(0)} = C_G^{(0)}$ and that the purely Gaussian terms do not grow to fast,

\[
\begin{align*}
\lim_{N \to \infty} N^{e(G) - e(G)/2} & \left[ C_G^{(k)} \right]_{\text{order 0 in } n} = 0 \quad \text{for } G \text{ Eulerian,} \\
N^{e(G) - e(G)/2} & \left[ C_G^{(k)} \right]_{\text{order 0 in } n} \quad \text{bounded for } G \text{ not Eulerian,} \\
N^{e(G) - e(G)/2} & \left[ C_G^{(k)} \right]_{\text{order 0 in } n} \quad \text{bounded for any } G.
\end{align*}
\]

This involves a combinatorial discussion based on the graphical interpretation of figure 4 that can be found in [6]. Let us simply mention that the terms that may violate the bounds are of higher order in $n$. Thus, they are harmless when taking the limit $n \to 0$ before the limit $N \to +\infty$. 

10
Finally, using (29) and the renormalisation group equation (35), the resolvent can be expressed as
\[ G(z) = \frac{1}{z} + \frac{1}{N^{3/2}z^2} \sum_{1 \leq i \leq N} [C_i(1/z;i)] \text{ order } 0 \text{ in } \eta. \] (38)

The scaling bounds for the non Gaussian cumulants impose, perturbatively in \(1/z\),
\[ \lim_{N \to \infty} \frac{1}{\sqrt{N}} [C''_{i}(1/z;i)] \text{ order } 0 \text{ in } \eta = 0. \] (39)

Therefore, only the Gaussian cumulants contribute and we recover Wigner’s semicircle law.

6 Conclusion and outlook

In this talk, we have argued that Wigner’s semicircle law remains valid for matrices with dependent entries. The deviation from the independent case is measured by the joint cumulants of the entries, which are assumed to fulfill some scaling bound for large \(N\). To establish this result, we have introduced an effective action for the replicas. This effective action obeys a renormalisation group equation that allowed us to prove perturbative bounds on the effective cumulants. As a consequence of these bounds, only the Gaussian terms contribute in the large \(N\) limit, thus establishing the validity of Wigner’s semicircle law.

It may also be of interest to investigate the case of the sum of a random matrix \(M\) and a deterministic one \(A\), see for instance [12] where such a model is discussed. In this case, the resolvent is expressed as
\[ G(z) = -\frac{1}{N} \frac{\partial}{\partial z} \int dX \exp \left\{ -\text{Tr}(X^\dagger(A+z)X) + V_0(X) \right\} \text{ order } 1 \text{ in } \eta. \] (40)

In our context, the deterministic matrix \(A\) induces a non trivial kinetic for the replicas. In particular, if \(A\) is a discrete Laplacian, it yields a non trivial renormalisation group flow that bears some similarities with the QFT renormalisation group. In this case, we expect to exploit the true power of the renormalisation group equation, with a discussion of fixed points and scaling dimensions.

Acknowledgements I wish to thank the organisers of the workshop, Mario Gattobigio, Thierry Grandou and Ralf Hoffmann for their kind invitation as well as Stan Brodsky for insightful remarks. I am also grateful to my collaborators, Dinh Long Vu and Adrian Tanasa.
