"Falling cat" connections and the momentum map

Marián Fecko &)

Abstract

We consider a standard symplectic dynamics on $TM$ generated by a natural Lagrangian $L$. The Lagrangian is assumed to be invariant with respect to the action $TR_g$ of a Lie group $G$ lifted from the free and proper action $R_g$ of $G$ on $M$. It is shown that under these conditions a connection on principal bundle $\pi : M \to M/G$ can be constructed based on the momentum map corresponding to the action $TR_g$. A simple explicit formula for the connection form is given. For the special case of the standard action of $G = SO(3)$ on $M = \mathbb{R}^3 \times \cdots \times \mathbb{R}^3$ corresponding to a rigid rotation of a N-particle system the formula obtained earlier by Guichardet and Shapere and Wilczek is reproduced.
1. Introduction

In their remarkable papers A. Guichardet [1] and A. Shapere and F. Wilczek [2] pointed out that the phenomenon of reorientation of deformable bodies (molecules represented by N point masses in [1] or cats, divers, astronauts etc. in [2]) in space, for a long time to be known in the case of cats to originate physically in the angular momentum conservation, lends itself to a simple and powerful description within the framework of the theory of connections (gauge structures). Namely they showed that in the center-of-mass system ($\vec{P} = 0$) the condition of vanishing of the total angular momentum ($\vec{L} = 0$) can be rephrased in terms of the SO(3)-connection in the principle bundle $\pi : M \to M/\text{SO}(3)$, where $M$ is the configuration space of the deformable body ($\mathbb{R}^{3N}$ minus some forbidden configurations in [1] or "the space of located shapes" in [2]), where SO(3) acts by rigid rotations (without deformation). In more detail the trajectories fulfilling $\vec{L} = 0$ represent the horizontal curves in the sense of the connection ("vibrational curves" in [1] as opposed to purely rotational ones given by (in general time dependent) rigid rotations).

In what follows we try to understand the origin of the connection within the standard framework [3] of lagrangian mechanics on $TM$.

It is known that the central object providing the link between the symmetries and conserved quantities in symplectic dynamics is the momentum map [4,5]. Now both $\vec{P}$ and $\vec{L}$ result (being linear in velocities) from the symmetries of rather special type, namely those lifted to $TM$ from $M$. That is why the situation under consideration is the following: we have a lagrangian system $(TM, L)$ with appropriate action of a Lie group $G$ lifted from the configuration space $M$. Then we show how one can construct (under some restrictions on the Lagrangian $L$) a connection in the principal bundle $\pi : M \to M/G$. This connection happens to coincide with the one in [1,2] in the case treated there, i.e. for $G = \text{SO}(3)$, $M$ being the configuration space of N-particle system.

The organization of the paper is the following. In Sec. 2 (as well as in Appendix A) the relevant facts concerning the momentum map within the context mentioned above are collected. The construction of the connection itself is described in Sec. 3, the general properties of the latter are discussed in Sec. 4. Several examples, including completely elementary ones as well as the N-particle system are given in Sec. 5. Some technicalities are treated in appendices.

2. The momentum map for the lifted action $TR_g$

Let

$$R_g : M \to M$$

be a right action of a Lie group $G$ on a manifold $M$. Then the tangent map

$$TR_g : TM \to TM$$

is a right action of $G$ on $TM$. Let $L : TM \to \mathbb{R}$ be a $G$-invariant Lagrangian, i.e.

$$L \circ TR_g \equiv (TR_g)^* L = L$$

for all $g \in G$. The (exact) symplectic form on $TM$ is given by ([3]; see Appendix A)

$$\omega_L = d\theta_L = dS(dL)$$

where (1,1)-type tensor field $S$ on $TM$ (almost tangent structure $\equiv$ vertical endomorphism) is a lift of the identity tensor on $M$ ($S = I^\uparrow$; in canonical local coordinates $x^i, v^i$ on $TM$, $S = dx^i \otimes \frac{\partial}{\partial v^i}$ or $S = dx^i \otimes \frac{\partial}{\partial x^i}$ if the notation $v^i \equiv \dot{x}^i$ is used). Since $\omega_L$ is to be maximum rank 2-form, the condition

$$\det(\frac{\partial^2 L}{\partial v^i \partial v^j}) \neq 0$$

must be fulfilled (nondegenerate Lagrangian).

Let $a \in \mathcal{G}$ (the Lie algebra of $G$), $X_a$ the corresponding fundamental field of the action $R_g$ on $M$. Then
the fundamental field of the lifted action \( T_R g \) is the complete lift \( \tilde{\mathcal{X}}_a \) (in coordinates if \( V = V^i \partial_i \) on \( M \) then \( \tilde{V} = V^i \partial_i + V^i_j \frac{\partial}{\partial y^j} \) on \( TM \). Now

\[
\mathcal{L}_{\tilde{\mathcal{X}}_a} \theta_L = (\mathcal{L}_{\tilde{\mathcal{X}}_a} S)(dL) + S(d\tilde{\mathcal{X}}_a L) = \theta_{\tilde{\mathcal{X}}_a} L
\]

(\( \mathcal{L}_{\varphi} S = 0 \) for any \( V \)). In the case of invariant Lagrangian (3) gives

\[
\tilde{\mathcal{X}}_a L = 0
\]

i.e.

\[
\mathcal{L}_{\tilde{\mathcal{X}}_a} \theta_L = 0
\]

Then

\[
i_{\tilde{\mathcal{X}}_a} d\theta_L + di_{\tilde{\mathcal{X}}_a} \theta_L = 0
\]

or

\[
i_{\tilde{\mathcal{X}}_a} \omega_L = -dP_a
\]

(\( \Rightarrow \tilde{\mathcal{X}}_a \) is hamiltonian field generated by \( P_a \)) where \( P_a : TM \to \mathbb{R} \) is defined by

\[
P_a := \langle \theta_L, \tilde{\mathcal{X}}_a \rangle \equiv S(dL, \tilde{\mathcal{X}}_a) = S(\tilde{\mathcal{X}}_a) L = X^*_a L
\]

(\( X^*_a \) is a vertical lift of \( X_a \)). Since \( P_a \) depends linearly on \( a \in G \), the momentum map associated with the (exact symplectic) action \( TR_g \) on \( TM \)

\[
P : TM \to G^*
\]

can be introduced by

\[
\langle P(v), a \rangle_0 := P_a(v) \ \ v \in TM
\]

where \( \langle \ldots \rangle_0 \) is the evaluation map (canonical pairing) for \( G \) and its dual \( G^* \). Fixing a basis \( E_{\alpha}, \alpha = 1, \ldots, \text{dim} G \) in \( G \) and the dual one \( E^\alpha \) in \( G^* \) one can write

\[
P = P_{\alpha} E^\alpha
\]

where

\[
P_\alpha \equiv P_{E_{\alpha}} : TM \to \mathbb{R}
\]

are the components of \( P \) with respect to \( E^\alpha \).

One verifies easily the important (equivariance) property of \( P \)

\[
(\mathcal{R}_g)^* P = \text{Ad}^*_g P
\]

or in components

\[
(\mathcal{R}_g)^* P_\alpha = (\text{Ad}^*_g)^{\beta}_{\alpha} P_\beta
\]

where \( \text{Ad}^*_g : G^* \to G^* \) is the coadjoint action of \( G \) on \( G^* \). If \( \Omega^k(M, \rho) \) denotes the space of k-forms of type \( \rho \) on \( G \)-space \( M \) (i.e. \( V \)-valued k-forms on \( M \) obeying \( R_g^*\sigma = \rho(g^{-1})\sigma \), \( \rho \) being a representation of \( G \) in \( V \)), we see that

\[
P \in \Omega^0(TM, \text{Ad}^*)
\]

- it is \( G^* \) - valued 0-form of type \( \text{Ad}^* \) on \( TM \). Thus a right action (1) of \( G \) on \( M \) which is a symmetry of a non-degenerate Lagrangian \( L \) (in the sense of (2) ) leads automatically to the existence of (5).

3. The construction of a connection form

Let \( R_g \) be the action (1). In order to obtain a principal \( G \)-bundle

\[
\pi : M \to M/G
\]
the action is to be in addition free (all isotropy groups trivial) and proper (the map \((g, x) \mapsto (x, R_g x)\) is proper, i.e. inverse images of compact sets are compact). A connection form on (6) is \(A \in \Omega^1(M, Ad)\) such that

\[ < A, X_a >= a \]  

holds for all \(a \in G\). Thus \(P \in \Omega^0(TM, Ad^*)\) is available whereas we need \(A \in \Omega^1(M, Ad)\). These two objects are different, but fortunately "not too much" and one can quite easily obtain some \(A\) from \(P\).

First there is a bijection between 1-forms on \(M\) and functions on \(TM\) "linear in velocities", viz.

\[ \sigma(v) := \langle \tilde{\sigma}, v \rangle_{\pi M}(v) \]  

\((\sigma \in \Omega^0(TM), \tilde{\sigma} \in \Omega^1(M))\), or in coordinates

\[ \sigma_i v^i \leftrightarrow \sigma_i dx^i \]

Then if our \(P\) were linear in velocities, one could associate with it \(\tilde{P} \in \Omega^1(M, Ad^*)\) by

\[ \langle \tilde{P}, v \rangle_{\pi M}(v) := P(v) \]

(the fact that \(\tilde{P}\) really remains to be \(Ad^*\)-type is easily verified). The demand of linearity in velocities of \(P_{\alpha}\) restricts the form of Lagrangian: according to (4)

\[ P_{\alpha}(v) = \frac{1}{2} g_{ij}(x) u^i u^j - U(x) \]  

(a standard Lagrangian for potential system with time-independent holonomic constraints). Then explicitly

\[ P_{\alpha}(v) = (X_\alpha^i L)(v) = X_\alpha^i(x) g_{ij}(x) u^j = (b_g X_\alpha)_j(x) u^j \]

and

\[ \tilde{P}_\alpha = (b_g X_\alpha)_j(x) dx^i = b_g X_\alpha \]

where \(b_g\) is the "lowering index" operator (by means of the metric tensor \(g\) on \(M\) given by the kinetic energy term in \(L\)) from vector to covector fields (the metric tensor \(g\) is denoted by the same letter as the group element \(g \in G\); the proper meaning of \(g\) is, however, always clear from the context). One also verifies that (see (3) and (8))

\[ L_{X_\alpha} g = 0 \]

i.e. \(G\) acts on \((M, g)\) as a group of isometries (\(X_\alpha\) are the Killing vectors).

The next step is a "correction" of \(Ad^*\)-type to \(Ad\)-type (needed for \(A\)). This can be done by composition with a map \(\hat{h} : G \rightarrow G^*\) induced by some \(Ad\)-invariant non-degenerate bilinear form \(h\) on \(G\) (see Appendix B). Then

\[ \hat{A} := \hat{h}^{-1} \circ \tilde{P} \in \Omega^1(M, Ad) \]

i.e. \(\hat{A}\) is already type \(Ad\) \(G\)-valued 1-form on \(M\).

Finally one has to check whether (7) is fulfilled. We have

\[ < \hat{A}, X_\alpha > = \hat{h}^{-1} < \tilde{P}, X_\alpha > = < \hat{h}^{-1} \tilde{P}_\beta, X_\alpha > = < b_g X_\beta, X_\alpha > \hat{h}^{\beta \gamma} E_\gamma = g(X_\alpha, X_\beta) h^{\beta \gamma} E_\gamma = C_\alpha^\gamma(x) E_\gamma \]

where

\[ C_\alpha^\gamma := g_{\alpha \beta}(x) h^{\beta \gamma} \]

\[ g_{\alpha \beta}(x) := g(X_\alpha, X_\beta) \]
Thus
\[ < \hat{A}, X_a > = C(x)(a) \]
where
\[ C(x) : \mathcal{G} \to \mathcal{G}, \ E_\alpha \mapsto C_\alpha^\beta E_\beta \]

According to Appendix C the $\mathcal{G}$-valued 1-form
\[ A := C^{-1} \circ \hat{A} = C^{-1} \circ \tilde{h}^{-1} \circ \tilde{P} \]
has already all the necessary properties of a connection form, i.e.
\[ R^* g A = \text{Ad}_{g^{-1}} A \]
\[ < A, X_a > = a \]
and defines thus a connection on $\pi : \mathcal{M} \to \mathcal{M}/G$. Explicitly we have
\[ A = C^{-1} \circ \tilde{h}^{-1}(\tilde{P}_\alpha E^\alpha) = \tilde{\tilde{P}}_\alpha h_{\alpha\beta} C^{-1}(E^\beta) = \]
\[ = \tilde{\tilde{P}}_\alpha (h_{\alpha\beta} h_{\beta\mu} g^{\mu\nu}) E_\nu = (g^{\alpha\beta} \tilde{\tilde{P}}_\beta) E_\alpha \]
where $g^{\alpha\beta}(x)$ is the inverse to $g_{\alpha\beta}(x)$ defined in (9). Thus it turns out to be given by a surprisingly simple expression, viz.
\[ A = A^\alpha E_\alpha = (g^{\alpha\beta} \tilde{\tilde{P}}_\beta) E_\alpha = g^{\alpha\beta}(\tilde{g} X_\beta) E_\alpha \quad (11) \]

Note: notice that the bilinear form $h_{\alpha\beta}$ was present on the scene only temporarily and it dropped out from the resulting formula (and thus one does not need it in fact for the construction of $A$).

4. Some properties of the connection given by $A$

Let $\gamma : \mathbb{R} \to \mathcal{M}$ be a curve on $\mathcal{M}$ representing some motion of the system under consideration. What does it mean in physical terms if it is purely horizontal (i.e. represents a parallel translation in the sense of $A$)? According to (11) we have
\[ < A, \dot{\gamma} > = 0 \quad \Rightarrow \quad < \tilde{\tilde{P}}_\alpha, \dot{\gamma} > = 0 \]
or
\[ P_\alpha(\dot{\gamma}(t)) = 0 \]
where $\dot{\gamma}$ is the natural lift of $\gamma$ to $T\mathcal{M}$ ( $(x^i(t), \dot{x}^i(t))$ in coordinates). Thus a horizontal curve is such motion of the system that all conserved quantities $P_\alpha$ have all the time zero value (remember $\tilde{P} = 0$, $\tilde{L} = 0$ in the Sec.1.).

Now let $W \in Hor_x \mathcal{M}$ be any horizontal vector. Then
\[ 0 = < A, W > = g^{\alpha\beta} < \tilde{\tilde{P}}_\beta, W > E_\alpha = g^{\alpha\beta} g(X_\beta, W) E_\alpha \]
or
\[ g(X_\alpha, W) = 0 \]
for all $\alpha$. But $X_\alpha$ just span the vertical subspace so that
\[ Ver_x \mathcal{M} \perp Hor_x \mathcal{M} \]

Thus the horizontal subspace is simply the orthogonal complement of the vertical one with respect to the scalar product in $T_x \mathcal{M}$ given by the kinetic energy metric tensor. Note that this serves as the definition of the connection (it gives it uniquely) in [1] (in the special case of $G = SO(3)$ etc. discussed in more detail further in Sec.5c.). In the approach presented here it came as its property.
5. Examples

We illustrate the construction of the connection form $A$ on three examples, the first two being completely elementary and the last one being that discussed in [1] and [2].

5.1. A point mass on a board

Let us have a (one dimensional) board of mass $m_1$ laying on the surface of the water and denote $x$ the distance of its left end from some reference point on the surface. Let $\xi$ denote the distance of a point mass $m_2$ from the left end of the board. The Lagrangian of the system reads

$$L(x, \xi, \dot{x}, \dot{\xi}) = \frac{1}{2}m_1\dot{x}^2 + \frac{1}{2}m_2(\dot{x} + \dot{\xi})^2 - U(\xi)$$

(interaction of the point mass $m_2$ with the board depends only on their relative position). The translational invariance of the system means that there is the action of $G \equiv \mathbb{R}$ on the configuration space $M[x, \xi]$ given by

$$R_b : (x, \xi) \mapsto (x + b, \xi) \quad b \in \mathbb{R} \equiv G$$

(the "unlocated shape" is given by the position of $m_2$ with respect to the board, i.e. by $\xi$) such that $L$ is invariant with respect to its lift

$$TR_b : (x, \xi, \dot{x}, \dot{\xi}) \mapsto (x + b, \xi, \dot{x}, \dot{\xi})$$

Now

$$X_1 = \partial_x \quad g_{11} \equiv g(X_1, X_1) = m_1 + m_2$$

$$A = A^1 E_1 = g^{11}((g X_1) E_1 = \frac{1}{m_1 + m_2}((m_1 + m_2)dx + m_2d\xi) = dx + \frac{m_2}{m_1 + m_2}d\xi$$

(one can take $E_1 = 1$ since $G = \mathbb{R}$). The curve $\gamma \leftrightarrow (x(t), \xi(t))$ is horizontal if $< A, \dot{\gamma} > \equiv < A, \dot{x} \theta_x + \dot{\xi} \theta_\xi > = 0$, i.e. if

$$\dot{x}(t) + \frac{m_2}{m_1 + m_2}\dot{\xi}(t) = 0$$

or

$$m_1\dot{x}(t) + m_2(\dot{x}(t) + \dot{\xi}(t)) = 0$$

which is just vanishing of the total (linear) momentum of the system.

5.2. A point mass on a gramophone disc

Let us have a gramophone disc (its moment of inertia with respect of the axis being $I$) and a point mass $m$ on it. If the angle $\alpha$ measures the orientation of the disc with respect to the outer space and $r, \varphi$ are the polar coordinates of the point mass $m$ with respect to the disc, the Lagrangian of the system is

$$L(r, \varphi, \alpha, \dot{r}, \dot{\varphi}, \dot{\alpha}) = \frac{1}{2}I\dot{\alpha}^2 + \frac{1}{2}m(r^2 + \dot{\alpha}^2 + \dot{\varphi}^2) - U(r, \varphi)$$

(interaction of the point mass $m$ with the disc depends only on their relative position). The rotational invariance of the system means that there is the action of $G \equiv SO(2)$ on the configuration space $M[r, \varphi, \alpha]$ given by

$$R_\beta : (r, \varphi, \alpha) \mapsto (r, \varphi, \alpha + \beta)$$
(the "unlocated shape" is given by the position of \( m \) with respect to the disc, i.e. by \( r, \varphi \)) such that \( L \) is invariant with respect to its lift

\[
TR_\beta : (r, \varphi, \alpha, \dot{r}, \dot{\varphi}, \dot{\alpha}) \mapsto (r, \varphi, \alpha + \beta, \dot{r}, \dot{\varphi}, \dot{\alpha})
\]

Now

\[
X_1 = \partial_\alpha \quad g_{11} \equiv g(X_1, X_1) = I + mr^2
\]

\[
A = A^1 E_1 = g^{11}(g_1 g_1) E_1 = \frac{1}{I + mr^2}((I + mr^2)d\alpha + mr^2d\varphi) = d\alpha + \frac{mr^2}{I + mr^2}d\varphi
\]

(one can take \( E_1 = 1 \) since \( G = \mathbb{R} \) as in the previous example). The curve \( \gamma \leftrightarrow (r(t), \varphi(t), \alpha(t)) \) is horizontal if

\[
\dot{\alpha}(t) + \frac{mr^2}{I + mr^2}\dot{\varphi}(t) = 0
\]

or

\[
I\dot{\alpha}(t) + mr^2(\dot{\alpha}(t) + \dot{\varphi}(t)) = 0
\]

which is just vanishing of the total angular momentum of the system.

If \( \sigma(t) \leftrightarrow (r(t), \varphi(t)) \) is a curve in the space of unlocated shapes \( M/G \), the resulting curve in \( M \) is \( \gamma(t) = \sigma^b(t) \) the horizontal lift of \( \sigma(t) \), given by \((r(t), \varphi(t), \alpha(t))\), where

\[
\alpha(t) = \alpha(0) + \int_0^t (\dot{\varphi}(s) \frac{mr^2(s)}{I + mr^2(s)})ds
\]

In particular, the holonomy (the angle corresponding to the element of \( SO(2) \) ) for the closed path (loop) \( \sigma(0) = \sigma(1) \) is

\[
\beta = \alpha(1) - \alpha(0) = -\int_0^1 \frac{mr^2(s)}{I + mr^2(s)}\dot{\varphi}(s)ds
\]

If for example the point goes round the disc once counterclockwise at constant distance \( r_0 \) \((r(t) = r_0, \varphi(t) = 2\pi t)\), the net rotation of the disc is

\[
\beta_0 = -2\pi \frac{I_0}{I + I_0} \quad I_0 \equiv mr^2_0
\]

(clockwise). Clearly \( \alpha \) does not change for radial motion (formally since \( A^1_1 = 0 \)).

There is nonzero curvature in this example being explicitly

\[
F = DA = dA = d\left(\frac{mr^2}{I + mr^2}\right) \wedge d\varphi = \left(\frac{mr^2}{I + mr^2}\right)'dr \wedge d\varphi = \frac{1}{2} F^{r \varphi}_{r \varphi} dr \wedge d\varphi
\]

5.3. \( N \)-particle system

Let \( \vec{r}_a \), \( a = 1, \ldots N \) denote the radius vector of \( a \)-th particle, \( x^i_a \) its \( i \)-th component \((i = 1, 2, 3)\), \( m_a \) its mass. There is a natural action of the Euclidean group \( G = E(3) \) on the configuration space of the \( N \)-particle system, consisting in rigid rotations and translations

\[
\vec{r}_a \mapsto \vec{r}_a B + \vec{b} \quad B \in SO(3)
\]

We will treat the rotations and the translations separately. The standard summation convention is adopted in what follows, i.e. the sum is implicit for pairs of equal indices, otherwise the symbol of sum is written explicitly. The translational subgroup acts by

\[
x^i_a \mapsto x^i_a + b^i
\]

If \( \mathcal{E}_i \) is the standard basis of the Lie algebra \( \mathbb{R}^3 \), i.e. \( (\mathcal{E}_i)^j = \delta^j_i \), then the corresponding fundamental field is

\[
X_i \equiv X_{\mathcal{E}_i} = \sum_a \partial^a_i = (\overrightarrow{\nabla}_1 + \cdots + \overrightarrow{\nabla}_N)_i
\]
\( \partial^\alpha_a \equiv \frac{\partial}{\partial x^a} \). The kinetic energy is

\[
T = \frac{1}{2} \sum_a m_a \dot{x}_a^k \dot{x}_a^k
\]

so that the metric tensor reads

\[
g = \sum_a m_a dx_a^k \otimes dx_a^k
\]

Then

\[
g(X_i, X_j) = m \delta_{ij}
\]

\((m \equiv \sum_a m_a \) is the total mass). Since

\[
\tilde{P}_i = g \cdot X_i = m_a dx_a^i
\]

we have the translational part of the connection

\[
A_{tr} = A_{tr}^i \mathcal{E}_i = \frac{1}{m} \delta_{ij} \tilde{P}_j \mathcal{E}_i = \frac{m_a dx_a^i}{m} \mathcal{E}_i
\]

The rotational subgroup acts by

\[
x_i^j \mapsto x_i^j B_j, \quad B \in SO(3)
\]

If \( E_i \) is the standard basis of the Lie algebra \( \text{so}(3) \), i.e. \( (E_i)_j^k = -\epsilon_{ijk} \), the corresponding fundamental field is

\[
X_i \equiv X_{E_i} = -\epsilon_{ijk} x_j^a \partial_a^k \equiv -(\vec{r}_a \times \vec{\nabla})_i
\]

Then

\[
g(X_i, X_j) = \sum_a (\delta_{ij} \vec{r}_a^2 - x_j^a x_i^a) = I_{ij}
\]

where \( I_{ij}(\vec{r}_1, \ldots, \vec{r}_N) \) is the inertia tensor of the configuration. Since

\[
\tilde{P}_i = g \cdot X_i = -\epsilon_{ijk} \sum_a m_a x_j^a dx_a^k \equiv -(\sum_a m_a \vec{r}_a \times d\vec{r}_a)_i
\]

we have the rotational part (the one computed in \([1,2]\)) of the connection

\[
A_{rot} = A_{rot}^i \mathcal{E}_i = I^{ij} \tilde{P}_j \mathcal{E}_i = -I^{ij} \left( \sum_a m_a \vec{r}_a \times d\vec{r}_a \right)_j \mathcal{E}_i
\]

\((I^{ij}) \) being the inverse matrix to \( I_{ij} \)). Putting both parts together the total (translational and rotational) connection form reads

\[
A = A_{tr} + A_{rot} = \frac{m_a dx_a^i}{m} \mathcal{E}_i + \left( -I^{ij} \left( \sum_a m_a \vec{r}_a \times d\vec{r}_a \right)_j \right) \mathcal{E}_i \equiv \frac{\tilde{\pi}^i}{m} \mathcal{E}_i - I^{ij} \tilde{L}_j \mathcal{E}_i
\]

\((\tilde{\pi}^i, \tilde{L}_i \) being the total linear and angular momentum 1-forms respectively on \( M \). Let \( \gamma(t) \leftrightarrow \vec{r}_a(t) \) be some motion of the system, now. Then it is horizontal provided that \( < A, \dot{\gamma} > = 0 \), i.e.

\[
\frac{m_a \ddot{x}_a^i(t)}{m} \mathcal{E}_i - \sum_a I^{ij}(\vec{r}_1(t), \ldots, \vec{r}_N(t)) m_a (\vec{r}_a(t) \times \dot{\vec{r}}_a(t))_j \mathcal{E}_i = 0
\]

or

\[
m_a \ddot{\vec{r}}_a(t) \equiv \tilde{P}(t) = \vec{0}
\]

\[
\sum_a m_a \vec{r}_a \times \dot{\vec{r}}_a \equiv \tilde{L} = \vec{0}
\]

Thus horizontal motion is such that the total (linear) momentum \( \tilde{P} \) as well as the total angular momentum \( \tilde{L} \) of the system vanish.

6. Conclusions and summary
In this paper we show that (under some restrictions mentioned in Sec.3.) given a natural lagrangian system \((TM, L)\) with symmetry \(G\) lifted from the configuration space \(M\) a connection in principle bundle \(\pi : M \to M/G\) can be constructed. The connection form \(A\) is given by remarkably simple explicit formula (11). It generalizes "angular momentum equals zero" [6] connection from [1],[2], corresponding to the group \(G = SO(3)\). The construction of \(A\) makes use of the momentum map of the associated exact symplectic action of \(G\) on \(TM\), making the link between the connection and conserved quantities explicit. A calculation shows that the vertical and horizontal subspaces are mutually orthogonal, which was used as the definition in [1].

Appendix A : Some useful facts concerning the \(TM\) geometry

Here we collect some more details on the constructions and objects on \(TM\), used in the main text (see [3]). If \(w \in T_xM\), its vertical lift to \(v \in TM\) \((\pi_M(v) = x)\) is the tangent vector in \(t = 0\) to the curve \(t \mapsto v + tw\). The vector field (on \(TM\)) obtained in such a way from the vector field \(V\) on \(M\) is denoted by \(V^\uparrow\). In canonical coordinates \((x^i, v^i)\) on \(TM\)

\[ V \equiv V^i(x)\partial_i \mapsto V^\uparrow \equiv V^i(x) \frac{\partial}{\partial v^i} \]

Let \(V\) be a vector field on \(M\), and let us denote its local flow \(\Phi_t\). Then the generator of the local flow \(T\Phi_t\) on \(TM\) is by definition the complete lift \(\tilde{V}\) of \(V\). In coordinates

\[ V \equiv V^i(x)\partial_i \mapsto \tilde{V} \equiv V^i(x) \frac{\partial}{\partial x^i} + V^i_j(x)w^j \frac{\partial}{\partial v^i} \]

If \(w \in T_vTM\), then the map \(S_v : T_vTM \to T_vTM\) \((w \mapsto (\pi_*w)^\uparrow)\) (the lift being to \(v)\) is linear, giving rise to the \((1,1)\)-tensor in \(T_vTM\). This pointwise construction defines a \((1,1)\)-tensor field \(S\) on \(TM\) (almost tangent structure \(\equiv\) vertical endomorphism), in coordinates \(S = dx^i \otimes \frac{\partial}{\partial v^i}\). Its properties used in the main text are (easily verified in coordinates)

\[ \mathcal{L}_V S = 0 \]

\[ S(\tilde{V}) = V^\uparrow \]

If \(B\) is \((1,1)\)-tensor field on \(M\), then its lift to \(TM\) is defined by \(B^\uparrow(w) := (B(\pi_*w))^\uparrow\). Then \(S = I^\uparrow\) (\(I\) being the unit tensor field on \(M\)).

Appendix B : The change of \(Ad^*\) to \(Ad\) via \(\hat{h}^{-1}\)

Let

\[ h : G \times G \to \mathbb{R} \]

be non-degenerate bilinear form on \(G\). It defines the map

\[ \hat{h} : G \to G^* \]

by \((a, b \in G)\)

\[ < \hat{h}(a), b >_G := h(a, b) \]

\((E_\alpha \mapsto h_{\alpha\beta}E^\beta)\). If \(h\) is Ad-invariant, i.e.

\[ h(Ad_g a, Ad_g b) = h(a, b), \]

then \(\hat{h}\) satisfies

\[ Ad_g^* \circ \hat{h} = \hat{h} \circ Ad_{g^{-1}} \]
Therefore
\[ R_g^* (\hat{h}^{-1} \circ \hat{P}) = \hat{h}^{-1} \circ R_g^* \hat{P} = \hat{h}^{-1} \circ Ad_g^* \hat{P} = Ad_{g^{-1}} (\hat{h}^{-1} \circ \hat{P}) \]
i.e. if \( \hat{P} \in \Omega^1(M, Ad^*) \), then \( \hat{A} \equiv \hat{h}^{-1} \circ \hat{P} \in \Omega^1(M, Ad) \).

**Appendix C**: Transformation of the connection form into the "canonical" form

Let \( \pi : P \to M \) be a principal bundle and let \( \overline{A} \in \Omega^1(P, Ad) \) define the connection by \( \text{Hor}_p P := \text{Ker} \overline{A}_p \). By definition \( \langle \overline{A}_p, X_a \rangle \in \mathcal{G} \), depending linearly on \( a \in \mathcal{G} \). Then
\[ \langle \overline{A}_p, X_a \rangle = C(p)(a) \quad (C1) \]
where
\[ C(p) : \mathcal{G} \to \mathcal{G} \]
is invertible (lest some \( X_a \) be horizontal). From
\[ R_g^* \overline{A} = Ad_{g^{-1}} \overline{A} \]
and \( (C1) \) one obtains
\[ C(pg) = Ad_{g^{-1}} \circ C(p) \circ Ad_g \]
and therefore
\[ A_p := C^{-1}(p) \circ \overline{A}_p \quad (C2) \]
has already the standard properties
\[ R_g^* A = Ad_{g^{-1}} A \]
\[ \langle A, X_a \rangle = a \quad (C3) \]
This shows that although the standard requirement \( (C3) \) on connection form can be modified to a more general one \( (C1) \), it can be always simplified back to the "canonical" choice \( (C3) \) via \( (C2) \).
