Abstract A novel Nicotinoyl fused peptide, Nicotinoyl-LVH, was synthesized by solid phase peptide synthesis method, purified, and tested in cultured skin cells. Nicotinoyl-LVH enhanced the expression level of collagen mRNA and its fragments in fibroblasts. These data show that this novel Nicotinoyl peptide is a promising biomaterial in the anti-aging functional cosmetic market.

Keywords Collagen synthesis · Cosmetic active ingredient · Nicotinoyl-LVH · Skin cell

Introduction Nicotinic acid, which is a common form of B-vitamin niacin, is a derivative of pyridine, with a carboxyl group at the 3-position. It is a precursor of the coenzymes nicotinamide adenine dinucleotide (NAD+) and nicotinamide adenine dinucleotide phosphate (NADP+), which are major coenzymes in vivo. NAD+ and NADP+ are coenzymes for many dehydrogenases, participating in hydrogen transfer processes, especially ATP synthesis for generating energy (Benavente et al. 2009). Niacin deficiency-induced pellagra is characterized by diarrhea, dermatitis, and dementia. The symptoms of dermatitis are casal collar lesions on the lower neck, hyperpigmentation, thickening of the skin, and inflammation of the mouth and tongue (Ishii and Nishihara 1981; Prakash et al. 2008; Wan et al. 2011). Therefore, this nutrient is used not only as a dietary supplement but also as a skin care and anti-aging product in cosmetic market; its global demand has been rising from 8,500 t/year to 40,000 in recent years (Cantarella et al. 2011).

There are many medical and cosmetic effects of nicotinoyl derivatives, including anti-inflammatory activity (Gieldanowski et al. 1987) and inhibition of melanin production (Kim et al. 2011; Kim et al. 2015), as well as the prevention of HIV infection (Uttekar et al. 2012).

Here, we synthesized a Nicotinoyl derivative, Nicotinoyl-LVH, a novel Nicotinoyl peptide aimed at enhancing the anti-wrinkle effect of the signal peptide. Synthetic peptides have been used in many functional cosmetics because of their defined actions and high stability. These peptides generally show anti-wrinkle effects. We investigated the expression level of biomarkers related to collagen synthesis in skin cell lines. The results showed that Nicotinoyl-LVH is promising anti-aging material because it enhances collagen synthesis.

Materials and Methods

Synthesis and purification of Nicotinoyl-LVH
Fmoc-His-OH, Fmoc-Leu-OH, Fmoc-Val-OH, Hydroxybenzotriazole (HOBr), 1, 8-Diazabicyclo[5,4,0]undec-7-ene and Diisopropyl-carbodiimide (DIC) were purchased from GLS (Shanghai, China). N,N-Dimethylformamide, Dichloromethane, Trifluoroacetic acid (TFA), acetonitrile and Diethylether were purchased from Daejung (Siheung, Korea). The structural formula of Nicotinoyl-LVH is shown in Fig. 1.
Structural analysis
Amino acids and nicotinic acid were coupled with resins by the general HOBT-DIC-mediated solid-phase peptide synthesis protocol (Amblard et al. 2006). After synthesis, sample was purified by reverse-phase high performance liquid chromatography (HPLC) (pump 600E, UV-484 detector, Gemini RP-C18 column 250×21.2 mm; Waters, Milford, MA, USA) for purification in a gradient of acetonitrile in 0.1 % TFA by using A Shimpack RP-C18 column (250*4.6 mm ID; 5 μm particle size; Shimadzu, Kyoto, Japan) for analysis. The elution gradient was 5 to 65 % and flow rate was 1.0 mL/min for 30 min. The target peptide peak was analyzed at 230 nm. A Matrix-Assisted Laser Desorption/Ionization Time-of-Flight Mass Spectrometry assay (MALDI-TOF-MS) was performed to determine the quality of synthetic Nicotinoyl-LVH using a mass spectrometer (Thermo Fisher Scientific, Waltham, MA, USA).

Cell culture
Human fibroblast CCD-986sk and Detroit 551 cells were routinely grown in Dulbecco’s modified Eagle’s medium (DMEM, Hyclone, Logan, UT, USA) containing 10 % fetal bovine serum (FBS) and antibiotic-antimycotic (Thermo Fisher Scientific) at 37°C in 5 % CO₂.

MTT assay
MTT assay was performed using the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazoliumbromide (MTT)-based Cell Viability and Proliferation Kit 1 (Sigma-Aldrich, St. Louis, MO, USA) following the suggested protocol. In brief, 1×10⁵ cells were seeded in 96-well micro plates and cultured for 24 h. Then the cells were treated with two Nicotinoyl peptides in different concentrations (0, 1, 5, 10, 20 μM) without FBS and incubated for 24 h. The media was replaced with 100 μL of MTT solution (0.5 mg/mL in DMEM) and incubated at 37°C for 4 h. After removing the MTT solution, MTT formazan dissolved in 100 μL of dimethyl sulfoxide was added and mixed for 10 min. Absorbance was measured at 540 nm using a Multiskan TM GO micro plate spectrophotometer (Thermo Fisher Scientific).

Quantitative real-time PCR
Total RNA isolation, cDNA synthesis, and reverse transcription were conducted using SuperPrep™ cell lysis & RT Kit for qPCR (TOYOBO, Osaka, Japan). The target mRNA was procollagen C-endepeptidase enhancer (PCOLCE) and GAPDH was used as the control gene for normalization using QuantiTect® Primer Assays (Cat no. QT01005725, QT01192646; Qiagen, Venlo, Netherlands). Real-time polymerase chain reaction (PCR) was performed in Rotor-Gene Q system (Qiagen).

Enzyme immunoassay
The detection of type I procollagen was carried with Procollagen Type I C-Peptide (PIP) EIA Kit (TaKaRa, Kusatsu, Japan) based...
on a sandwich immunoassay method. In brief, $1 \times 10^5$ cells were seeded in 48-well microplates and cultured for 24 h. Then cells were treated with two Nicotinoyl peptides in different concentration (0, 1, 5, 10, 20 µM) without FBS and incubated for 24 h. The amount of PIP was measured from cultured media by measuring the absorbance at 450 nm using Multiskan TM GO Microplate Spectrophotometer plate reader (Thermo Fisher Scientific). The concentration of PIP was determined by comparing with the standards plotted on a standard curve (Masamune et al. 2013).

**Immunofluorescence staining and fluorescence imaging**
For immunofluorescence staining, the following protocol was carried out at room temperature: cells were first washed with PBS and then fixed with 4 % paraformaldehyde (Sigma) for 15 min, followed by three times of washing with PBS. After permeabilization with 0.1 % triton X-100 (Daejung) for 2 min, cells were washed with PBS containing 0.5 % BSA (PBB). After blocking reaction in PBS solution containing 2 % BSA (Bovogen, Victoria, Australia) for 1 h, cells were incubated for 1 h with anti-ProCOL1A2 antibody (sc-8785, Santa Cruz Biotechnology, Dallas, Texas, USA). Cells were then washed three times with PBB and then incubated with a secondary antibody Alexa488-labeled anti-goat IgG (Thermo Fisher Scientific) for 1 h. Finally, cells were again washed three times with PBB and incubated with 4',6-diamidino-2-phenylindole (DAPI, Thermo Fisher Scientific) for 10 min. Cells were then washed with PBS and inspected by fluorescent microscope equipped with a CCD camera system (DP30, Olympus, Tokyo, Japan) with Cell-R system (Olympus). This analysis was performed by using image analysis software, ImageJ.

**Results and Discussion**

**Structural analysis and Cell viability assay**
The structure of synthesized Nicotinoyl-LVH was analyzed by HPLC and mass spectroscopy. There was one main peak of Nicotinoyl-LVH in each spectrograph by HPLC (Fig. 1B), and the molecular weight corresponding to Nicotinoyl-LVH was confirmed by MALDI-TOF-MS (Fig. 1C).

Then, we investigated the effect of Nicotinoyl-LVH on cell viability by using the MTT assay in human fibroblast CCD-986sk cells. As shown in Fig. 2, Nicotinoyl-LVH showed no cytotoxicity in the concentration range 1–20 µM, indicating it does not affect cell viability (Fig. 2).

**Collagen synthesis measurement**
Collagen is one of the essential components of extracellular matrix (ECM). The degradation of extracellular collagen induces ECM disorganization and influences dermal moisture and elasticity. Collagens are synthesized as precursor molecules called procollagens. These contain additional peptide sequences, at both the N-terminal and the C-terminal ends (propeptides). To polymerize collagen fibrils at ECM, these propeptides have to cleave off from the collagen (Francini et al. 1993). We estimated the effect of Nicotinoyl-LVH on intra- and extracellular biomarkers related to collagen synthesis. First, we estimated the mRNA

![Fig. 3 Measurement of collagen synthesis level after nicotinoyl peptide treatments (A) Intracellular PCOLCE mRNA expression level. (B) Procollagen type I C-peptide level in the extracellular matrix](image)
expression level of procollagen C-endopeptidase enhancer (PCOLCE). PCOLCE binds to C-peptide of procollagen, and induces its cleavage for collagen polymerization. As shown in Fig. 3A, Nicotinoyl-LVH dose-dependently increased the gene expression of PCOLCE to 2.5 times the maximum in control. We also detected procollagen type I C-peptide (PIP) by an enzyme immunoassay. The amount of free propeptides in media reflected the amount of collagen molecules synthesized. There was also an increase in the amount of procollagen in media, indicating the improvement of collagen synthesis after treatment of Nicotinoyl-LVH (Fig. 3B), as compared with nicotinic acid which did not affect collagen synthesis of fibroblasts.

To estimate the amount of intracellular procollagen directly, we carried out immunostaining of Detroit 551 cells (Fig. 4A). The fluorescence intensity was analyzed to evaluate intracellular procollagen. There was an obviously enhancement of the amount of intracellular procollagen after Nicotinoyl-LVH treatment (Fig. 4B). We also analyzed relative fluorescence intensities of cytoplasm domain. The fluorescence intensities of procollagen in Nicotinoyl-LVH-treated cells were 1.6-fold higher than that in non-treated cells (Fig. 4B). Statistical significance was confirmed by Student’s t-test, when comparing fluorescent intensities of Nicotinoyl-LVH-treated and non-treated cells. These results showed Nicotinoyl-LVH induced procollagen expression in skin cells and enhanced collagen synthesis at ECM.

We synthesized a novel peptide derivative fused to nicotinic acid. Nicotinoyl-LVH did not show cytotoxicity and improved intracellular procollagen synthesis, implying ECM regeneration (Ganceviciene et al. 2012). This result showed that it has anti-wrinkle effects in human fibroblasts, which indicates that Nicotinoyl-LVH may be a promising candidate for therapeutic and industrial applications.
