Neuroprotective therapies based on brain-derived neurotrophic factor (BDNF) administration have been proposed for Huntington’s disease (HD) treatment. However, our group has recently reported reduced levels of TrkB in HD mouse models and HD human brain suggesting that besides a decrease on BDNF levels a reduction of TrkB expression could also contribute to diminished neurotrophic support in HD. BDNF can also bind to p75 neurotrophin receptor (p75\textsuperscript{NTR}) modulating TrkB signaling. Therefore, in this study we have analyzed the levels of p75\textsuperscript{NTR} in several HD models, as well as in HD human brain. Our data demonstrates a p75\textsuperscript{NTR}/TrkB imbalance in the striatum of two different HD mouse models, Hdh\textsuperscript{Q111/Q111} homozygous knockin mice and R6/1 mice that was also manifested in the putamen of HD patients. The imbalance between TrkB and p75\textsuperscript{NTR} levels in a HD cellular model did not affect BDNF-mediated TrkB activation of prosurvival pathways but induced activation of apoptotic cascades as demonstrated by increased JNK phosphorylation. Moreover, BDNF failed to protect mutant huntingtin striatal cells transfected with p75\textsuperscript{NTR} against NMDA-mediated excitotoxicity, which was associated with decreased Akt phosphorylation. Interestingly, lack of Akt activation following BDNF and NMDA treatment correlated with increased PP1 levels. Accordingly, pharmacological inhibition of PP1 by okadaic acid (OA) prevented mutant huntingtin striatal cell death induced by NMDA and BDNF. Altogether, our findings demonstrate that the p75\textsuperscript{NTR}/TrkB imbalance induced by mutant huntingtin in striatal cells associated with the aberrant activity of PP1 disturbs BDNF neuroprotection likely contributing to increasing striatal vulnerability in HD. On the basis of this data we hypothesize that normalization of p75\textsuperscript{NTR} and/or TrkB expression or their signaling will improve BDNF neuroprotective therapies in HD.

Subject Category: Neuroscience

Deficits of neurotrophic support caused by reduced levels of brain-derived neurotrophic factor (BDNF) have been implicated in the selective vulnerability of striatal neurons in Huntington’s disease (HD).\textsuperscript{1} Neuroprotective therapies based on BDNF administration have been proposed to slow or prevent the HD disease progression. However, the effectiveness of BDNF may depend on the proper expression of its neuronal receptor TrkB. Indeed, reduced striatal TrkB expression has been reported in knockin HD cellular and mouse models, exon-1 HD transgenic mice and HD human brain,\textsuperscript{2–4} which suggests that mutant huntingtin could lead to reduced neurotrophic support not only by altering BDNF levels but also by affecting TrkB expression. This scenario can still be more complex as BDNF also binds to p75\textsuperscript{NTR}, a member of the tumor necrosis factor receptor superfamily.\textsuperscript{5} In contrast to Trk receptors, which have a well-defined trophic role, p75\textsuperscript{NTR} may promote a variety of complex and sometimes opposing functions ranging from trophism to apoptosis depending on the cellular context and coexpression with Trk receptors.\textsuperscript{6,7} Thus, p75\textsuperscript{NTR} can either potentiate or reduce neurotrophic Trk receptor function or act independently to induce apoptotic signaling cascades.\textsuperscript{5,6,9} In the adult brain, p75\textsuperscript{NTR} expression is downregulated in most brain areas.\textsuperscript{10,11} However, in damaged or diseased conditions p75\textsuperscript{NTR} expression is rapidly induced, which has been associated with neuronal cell death.\textsuperscript{7,12} Thus, in neonatal mice brain, NMDA-induced injury is associated with upregulation of p75\textsuperscript{NTR},\textsuperscript{13,14} while in rats excitotoxicity induced by kainate administration causes an increase on p75\textsuperscript{NTR} levels accompanied by a significant cell death.\textsuperscript{15} Importantly, in HD, striatal neurons are selectively vulnerable to glutamate-induced neurotoxicity suggesting that excitotoxicity has an important role in HD striatal neurodegeneration.\textsuperscript{16} In this view, Zuccato \textit{et al.} have demonstrated increased p75\textsuperscript{NTR} but reduced TrkB mRNA expression in the caudate but not in the cortex of HD patients\textsuperscript{4} while impaired TrkB-mediated ERK1/2 activation was recently reported by

our group in HD striatal cell lines.\textsuperscript{3} Altogether, this data suggest that neurotrophic deficits in HD could account not only for BDNF reduction but also for an imbalance between TrkB and p75\textsuperscript{NTR}–mediated cell signaling. To test this hypothesis we have analyzed the levels of p75\textsuperscript{NTR} and TrkB in the striatum of two distinct HD mouse models at different HD pathological stages, as well as in the putamen of HD patients. We found an imbalance between p75\textsuperscript{NTR} and TrkB levels that was associated with a reduction of BDNF–mediated neurotropism against NMDA excitotoxicity. Altogether, our findings support the idea that normalization of TrkB and p75\textsuperscript{NTR} protein levels or their functional signaling cross-talk would be a major step to improve neuroprotective therapies with BDNF in HD.

Results

p75\textsuperscript{NTR} and TrkB protein levels are altered in the striatum of R6/1 mice. Reduced BDNF neuroprotection contributes to striatal vulnerability in HD.\textsuperscript{17} Given that BDNF effects can be mediated by TrkB and p75\textsuperscript{NTR} we analyzed the expression of these receptors in the striatum of wild-type and mutant huntingtin R6/1 mice at different HD pathological stages (Figure 1a). p75\textsuperscript{NTR} protein levels were significantly increased in the striatum of R6/1 mice at 12 weeks of age (\textasciitilde50\%) an increase that was even more evident at 30 weeks (\textasciitilde120\%) revealing an effect of age and genotype on changes in p75\textsuperscript{NTR} (\(F_2,18 = 4.133; P<0.05\)). By contrast, a significant reduction of TrkB was found in R6/1 only at late disease stages (\textasciitilde40\%). As we described that reduced TrkB was associated with decreased TrkB transcription\textsuperscript{2} we examined whether increased p75\textsuperscript{NTR} mRNA expression could account for upregulation of p75\textsuperscript{NTR} protein levels. A significant increase in p75\textsuperscript{NTR} mRNA was found in the striatum of R6/1 mice at 30 weeks of age (WT:1.0 \(\pm\) 0.3 and R6/1:2.3 \(\pm\) 0.4, \(P<0.05\)) indicating that both p75\textsuperscript{NTR} mRNA and protein are increased in R6/1 mice. To further evaluate the expression and distribution of p75\textsuperscript{NTR} immunohistochemistry analysis was performed in striatal slices from wild-type and R6/1 mice at 30 weeks of age (Figure 1b). According to the biochemical data a significant increase (\textasciitilde30\%) on p75\textsuperscript{NTR} staining was revealed in mutant compared with wild-type mice. As striatal neuronal loss has a characteristic rostro-caudal gradient of pathological damage,\textsuperscript{18} p75\textsuperscript{NTR} levels were analyzed on coronal sections across the rostro-caudal extension of the striatum (Figure 1c). Significant

*p75<sup>NTR</sup>* and TrkB protein levels are also modified in the striatum of full-length *Hdh<sub>Q111/111</sub>* mutant mice. (a) Representative immunoblots showing the levels of *p75<sup>NTR</sup>* <br>TrkB and β-actin as a loading control in striatal extracts obtained from wild-type *Hdh<sub>Q7/7</sub>* and mutant *Hdh<sub>Q111/111</sub>* mice at 1, 2 and 12 months of age. The histograms represent the relative levels of *p75<sup>NTR</sup>* and TrkB expressed as percentage of wild-type values. Values are given as mean ± S.E.M. of 5–6 independent samples. Data was analyzed by two-way ANOVA followed by Student’s t-test. *P<sub>o</sub>0.05; **P<sub>o</sub>0.01; ***P<sub>o</sub>0.001 respect to wild-type mice. (b) (Upper panel) double immunostaining showing *p75<sup>NTR</sup>* and DARPP32 in the striatum of wild-type (*Hdh<sub>Q7/7</sub>*) and mutant (*Hdh<sub>Q111/111</sub>*) mice at 12 months of age. Some cells are single-labeled for *p75<sup>NTR</sup>* (arrows), whereas a high proportion of cells are double-labeled for *p75<sup>NTR</sup>* and DARPP32 in both wild-type and HD mutant mice (arrowheads). (Middle panel) double immunostaining showing *p75<sup>NTR</sup>* and parvalbumine staining in the striatum of mutant *Hdh<sub>Q111/111</sub>* mice at 12 months of age. Most of the parvalbumine-positive neurons are also positive for *p75<sup>NTR</sup>*. (Bottom panel) Double immunostaining showing *p75<sup>NTR</sup>* and GFAP in the striatum of mutant (*Hdh<sub>Q111/111</sub>*) mice at 12 months of age. *p75<sup>NTR</sup>* and GFAP immunoreactivity demonstrates lack of colocalization. Scale Bar, 25 μm
The putamen of HD patients shows altered p75NTR and TrkB protein levels. (a) Human brain tissue from 10 control and 9 HD cases were analyzed by western blot. Immunoblots were probed with p75NTR, TrkB, β-actin as loading control and NeuN and GFAP as neuronal and astroglial markers, respectively. Scatter plots display the relative levels of p75NTR and TrkB normalized to actin, NeuN or GFAP. The horizontal line represents the normalized mean value in control and HD subjects. Data was analyzed using Student’s t-test. **P < 0.01, ***P < 0.001 compared with control. (b) Immunohistochemistry in caudate-putamen of HD brain (Vonsatel grade 1) showing extensive colocalization between DARPP32 (striatal neuronal marker) and p75NTR. Nuclear staining was revealed by DAPI labeling to show that glia cells (arrows) are not positive for p75NTR in contrast to neuronal cells (arrowheads). Scale bar, 10 μm
differences were detected along the rostro-caudal striatum with the rostral sections having significantly more p75NTR staining, which suggest a correlation between p75NTR levels and striatal atrophy.

Knockin HdhQ111/111 mutant mice also display p75NTR/TrkB imbalance in the striatum. We next analyzed whether in a different HD mouse model expressing endogenous levels of full-length mutant huntingtin (HdhQ111/111) the expression of both receptors was also altered. No significant differences on p75NTR levels between wild-type and mutant mice were found at 1 month of age while a significant increase was evident at 2 months (~80%), 5 and 8 months (~90%) and 12 months of age (~135%) (Figure 2a). Similar to that observed in R6/1 mice the increase on p75NTR was (1) progressive, starting at 2 months of age and worsening thereafter (F(1,32) = 7.415; P < 0.001) and (2) associated with upregulation of p75NTR mRNA expression (HdhQ111/111: 1.0 ± 0.1 and HdhQ111/111:1.8 ± 0.3, P < 0.05). When TrkB levels were examined we found a significant decrease (~40%) at early HD stages that was sustained along the disease progression (Figure 2a). Given that p75NTR can be upregulated by neurons or glia double immunostaining for p75NTR, DARPP32 and parvalbumin as GABAergic striatal neuronal markers and GFAP as astroglial marker was performed (Figure 2b). Confocal analysis revealed that the majority of DARPP32-positive cells were also positive for p75NTR indicating a neuronal distribution of p75NTR. We also observed p75NTR-positive cells that were negative for DARPP32 that could correspond to parvalbumin interneurons. Double immunolabeling confirm colocalization between p75NTR and parvalbumin indicating that p75NTR was also localized in these GABAergic interneurons. Importantly, p75NTR immunoreactivity failed to colocalize with GFAP demonstrating that p75NTR was not detectable in astrocytes.

Changes on p75NTR and TrkB protein levels are manifested in the putamen of HD patients. Next we analyzed whether aberrant p75NTR and TrkB protein levels were recapitulated in HD human brain. Upon normalization to actin we found in HD samples a significant increase in p75NTR (~100%) together with a decrease in TrkB (~60%) levels compared with control samples (Figure 3a). The levels of p75NTR were also normalized to NeuN and GFAP. Normalization to GFAP yielded no significant changes compared with control samples while a significant increase was found when normalized to NeuN (~300%). To further

Figure 4 BDNF induces prosapoptotic signaling cascades in corticostriatal slices from mutant HdhQ111/111 mice. Seven-month-old wild-type (HdhQ111) and mutant (HdhQ111/111) mice were injected with GFP-AAV scramble shRNA (scramble shRNA) or GFP-AAV p75shRNA (p75shRNA) on postnatal day 1 and corticostriatal slices obtained 1 month later. Slices were incubated with BDNF (200 ng/ml) and cell survival determined by a CKK8 assay 24 h later. (a) (Left) Representative immunoblots showing the levels of p75NTR and α-tubulin as a loading control in extracts obtained from corticostriatal slices obtained from wild-type HdhQ111 and mutant HdhQ111/111 mice injected with AAV expressing scramble shRNA or p75 shRNA. The histogram represents the relative levels of p75NTR expressed as percentage of wild-type values. Values are given as mean ± S.E.M. of four slices/condition/experiment (n = 3). Data was analyzed by Student’s t test. *P < 0.05 respect to wild-type mice. (Right) Confocal microscopy of corticostriatal slices transduced with AAV expressing p75shRNA or scramble shRNA and labeled for p75NTR expression (red). Transduction of p75shRNA results in lack of p75NTR expression as indicated by the absence of red p75NTR labeling in GFP-positive cells. (b) Histograms showing the quantification of cell survival expressed as the percentage of scramble shRNA transduced cells (control). Values are given as mean ± S.E.M. of four slices/condition/experiment (n = 3). Data was analyzed by one-way ANOVA followed by Turkey’s Multiple comparison test or Student’s t test *P < 0.05; **P < 0.01 respect to wild-type mice, *P < 0.05 respect to scramble shRNA + BDNF treatment. (c) Representative immunoblots showing the levels of JNK, p-JNK and α-tubulin as a loading control in extracts obtained from corticostriatal slices obtained from wild-type HdhQ111 and mutant HdhQ111/111 mice and incubated with BDNF for 24 h. The histograms represent the relative p-JNK/JNK ratios considering 100% the ratio obtained in scramble shRNA conditions (control). Values are given as mean ± S.E.M. of three independent experiments. Data was analyzed by Student’s t test *P < 0.05 respect to wild-type mice, *P < 0.05 respect to scramble shRNA + BDNF treatment.
confirm the neuronal distribution of p75NTR in HD human brain double immunolabeling for p75NTR and DARPP32 was performed in HD caudate-putamen brain sections. Confocal analysis demonstrated colocalization of p75NTR and DARPP32 revealing that p75NTR is primary neuronal in HD human brain, which agrees with our immunohistochemistry data in knockin HD mutant mice. Consistently, glia cells identified by DAPI staining as cells with bright and condensed nuclei were negative for p75NTR immunostaining.

**BDNF treatment reduces the cell survival of corticostriatal slices from knockin HdhQ111/111Q mutant mice.** Given the importance of TrkB to mediate BDNF neuroprotection we analyzed whether the p75NTR/TrkB imbalance in HD might influence BDNF-induced cell survival. To this aim adeno-associated viruses (AAV) expressing p75 shRNA or scramble shRNA were bilaterally injected into the striatum of wild-type and HD mice, corticostriatal slices obtained and cell survival analyzed following BDNF treatment (Figure 4). First, we examined viability of tissue slices by fluorescence microscopy using calcein as a vital dye and propidium iodide as a marker for cell death. An optimal preservation of slices as judged from the cell viability achieved was found (Supplementary Figure S1a). Then we analyzed the efficiency of AAV-p75shRNA to knockdown p75NTR. Western blot analysis demonstrated a significant reduction of p75NTR in wild-type and mutant corticostriatal slices (~50% and 40%, respectively; P<0.05). Histological analysis by confocal microscopy further confirmed lack of p75NTR expression in neurons transduced with p75shRNA (Figure 4a). Finally, cell survival was evaluated in BDNF-treated slices (Figure 4b). BDNF incubation increased the cell survival of wild-type corticostriatal slices (~40%) while a significant reduction was found in HD slices (~30%) suggesting that p75NTR/TrkB imbalance negatively modulates BDNF neuroprotection. Interestingly, reduction of p75NTR levels in the striatum of wild-type mice increased the survival of corticostriatal slices (~50%) while in HD mice not only increased the cell survival but also prevented the cell death induced by BDNF (Figure 4b). Because JNK activation mediates the proapoptotic actions of neurotrophins20,21 we next determined whether the cell death induced by BDNF was associated with increased JNK phosphorylation. A significant increase in p-JNK levels (~20%) without changes in total JNK were found in STHdh7/7Q cells expressing GFP-p75 but not GFP (Figure 5b). Then we analyzed whether BDNF-mediated activation of Akt and ERK1/2 pathways was preserved in STHdh7/7Q and STHdh7/7Q cells transfected with GFP-p75. It is important to mention that STHdh7/7Q cells exhibit increased p-Akt and decreased p-ERK levels at basal conditions,13,22 levels that were not altered by overexpression of p75NTR (Supplementary Figure S2c). Western blot analysis revealed that BDNF treatment induced a significant increase in Akt phosphorylation in both STHdh7/7Q and STHdh7/7Q cells transfected with GFP (~100%) and GFP-p75 (~200%) (Figure 5c). Interestingly, the increase on Akt phosphorylation was significantly higher in GFP-p75-transfected cells than in GFP cells suggesting that overexpression of p75NTR facilitates TrkB-mediated Akt activation. When ERK1/2 phosphorylation was analyzed we found that BDNF treatment induced a robust and similar activation (~140%) of p-ERK1/2 in GFP and GFP-p75 STHdh7/7Q cells (Figure 5c). In contrast, ERK1/2 phosphorylation was not increased in BDNF-treated GFP or GFP-p75 STHdh7/7Q cells, which agrees with our own published data showing impaired TrkB-mediated ERK1/2 activation in mutant cells.3 These findings indicate that altered p75NTR/TrkB expression modifies BDNF-mediated neuroprotection by increasing the activation of the proapoptotic pathway JNK.

**BDNF fails to protect GFP-p75-transfected STHdh7/7Q mutant cells against NMDA-induced excitotoxicity.** BDNF-mediated TrkB signaling is required to protect striatal neurons against NMDA-induced excitotoxicity,23 which is well known to contributes to the striatal cell loss in HD.16 Therefore, we investigated whether the p75NTR/TrkB imbalance could affect BDNF neuroprotection against NMDA. GFP or GFP-p75 transfected STHdh7/7Q and STHdh7/7Q cells were treated with BDNF before NMDA exposure and cell survival was analyzed 24 h later (Figure 6). NMDA treatment induced a significant reduction of cell survival in both STHdh7/7Q (~30%) and STHdh7/7Q cells (~50%) (Figure 6a). Addition of BDNF before NMDA completely prevented NMDA-induced cell death in STHdh7/7Q cells independently of p75NTR expression (Figure 6a). Surprisingly, in GFP-p75 STHdh7/7Q cells BDNF treatment not only failed to protect striatal cells against NMDA-induced cell death but also potentiated it (~20%). As activation of caspase-3 following NMDA treatment was described in this mutant huntingtin cell line24 we evaluated whether caspase-3 activation was involved in the lack of BDNF neuroprotection against NMDA (Figure 6b). Similar caspase-3 activation was found in GFP or GFP-p75 mutant cells following NMDA incubation (~40%). However, we found that BDNF observed in HD mutant mice, STHdh7/7Q and STHdh111/111Q cells were transfected with GFP or GFP-p75NTR (Supplementary Figure S2b) and then incubated with BDNF. BDNF treatment induced a reduction of cell survival (~20%) in GFP-p75 STHdh111/111Q cells but not in GFP-p75 STHdh7/7Q cells (Figure 5a) consistent with our data in HD corticostriatal slices. Next, we analyzed whether the reduction on cell survival was also related with increased JNK phosphorylation. A significant increase in p-JNK levels (~20%) without changes in total JNK were found in STHdh7/7Q cells expressing GFP-p75 but not GFP (Figure 5b). Then we analyzed whether BDNF-mediated activation of Akt and ERK1/2 pathways was preserved in STHdh7/7Q and STHdh7/7Q cells transfected with GFP-p75. It is important to mention that STHdh7/7Q cells exhibit increased p-Akt and decreased p-ERK levels at basal conditions,13,22 levels that were not altered by overexpression of p75NTR (Supplementary Figure S2c). Western blot analysis revealed that BDNF treatment induced a significant increase in Akt phosphorylation in both STHdh7/7Q and STHdh7/7Q cells transfected with GFP (~100%) and GFP-p75 (~200%) (Figure 5c). Interestingly, the increase on Akt phosphorylation was significantly higher in GFP-p75-transfected cells than in GFP cells suggesting that overexpression of p75NTR facilitates TrkB-mediated Akt activation. When ERK1/2 phosphorylation was analyzed we found that BDNF treatment induced a robust and similar activation (~140%) of p-ERK1/2 in GFP and GFP-p75 STHdh7/7Q cells (Figure 5c). In contrast, ERK1/2 phosphorylation was not increased in BDNF-treated GFP or GFP-p75 STHdh7/7Q cells, which agrees with our own published data showing impaired TrkB-mediated ERK1/2 activation in mutant cells.3 These findings indicate that altered p75NTR/TrkB expression modifies BDNF-mediated neuroprotection by increasing the activation of the proapoptotic pathway JNK.
Figure 5  BDNF-mediated reduction of the survival of GFP-p75 ST111/111Q mutant cells is associated with activation of apoptotic pathways. Wild-type (ST7/7Q) and mutant (ST111/111Q) huntingtin striatal cells transfected with GFP or GFP-p75 were treated with BDNF (50 ng/ml, 30 min) and cell survival was evaluated 24 h later by scoring the percentage of Hoechst-stained nuclei. (a) Photomicrographs of ST7/7Q and ST111/111Q cells stained with Hoechst showing a significant reduction of cell survival in BDNF-treated GFP-p75 ST111/111Q cells. Scale bar, 10 μm. Quantification of surviving cells is shown as the percentage of total cells in control conditions. The results are representative of seven independent experiments performed in triplicate and are expressed as the mean ± S.E.M. Data was analyzed by one-way ANOVA followed by Student’s t-test *P<0.05 versus vehicle-treated GFP-p75 mutant cells. (b) Representative immunoblot showing the levels of JNK, p-JNK and α-tubulin as a loading control in striatal extracts obtained from mutant ST111/111Q cells incubated with BDNF (50 ng/ml, 3h). The histogram represents the relative p-JNK/JNK ratio considering 100% the ratio obtained in control conditions (vehicle). Values are given as mean ± S.E.M. Data was analyzed by Student’s t-test. ***P<0.001 versus vehicle-treated GFP-p75 mutant cells. (c) Representative immunoblots showing the levels of Ser-473-Akt (p-Akt), Akt, phosphoERK1/2 (p-ERK), ERK1/2 and α-tubulin as a loading control in striatal extracts obtained from wild-type (ST7/7Q) and mutant (ST111/111Q) cells transfected with GFP or GFP-p75 and treated with BDNF (50 ng/ml) for the indicated time points. Blots are representative of four independent experiments. The histograms represent the relative p-Akt/Akt and p-ERK/ERK ratios considering 100% the ratio obtained in control condition (vehicle). Values are given as mean ± S.E.M. Data was analyzed by Student’s t-test. + P<0.05, + + P<0.01 versus vehicle-treated GFP cells, *P<0.05, **P<0.01, ***P<0.001 versus vehicle-treated GFP-p75 cells, $P<0.05$ versus BDNF-treated GFP cells.
completely blocked NMDA-induced activation of caspase-3 in GFP mutant cells while a significant increase (∼75%) was still observed in GFP-p75 mutant cells consistent with the lack of BDNF neuroprotection against NMDA.

**Lack of BDNF neuroprotection against NMDA correlates with decreased Akt phosphorylation in GFP-p75**  

*S*THdh*111/111Q* mutant cells. As BDNF did not protect GFP-p75 *S*THdh*111/111Q* cells against NMDA we analyzed activation of Akt and ERK1/2 following BDNF and NMDA treatment. GFP and GFP-p75 transfected *S*THdh*7/7Q* and *S*THdh*111/111Q* cells were incubated with NMDA alone or with BDNF before NMDA and Akt and ERK1/2 phosphorylation analyzed by western blot (Figure 7a). NMDA treatment induced a significant increase in p-Akt levels in both *S*THdh*7/7Q* (GFP: ∼80% and GFP-p75: ∼150%) and *S*THdh*111/111Q* cells (∼100%) independently of p75NTR transfection. We then analyzed whether BDNF treatment could modify this NMDA-induced Akt phosphorylation. We found that BDNF prevented NMDA-mediated Akt phosphorylation in *S*THdh*7/7Q* cells (GFP or GFP-p75) suggesting that BDNF desensitize wild-type cells to further Akt activation by...
NMDA. Similar results were found when GFP-STHdh111/111Q cells were analyzed. However, in GFP-p75 STHdh111/111Q cells BDNF preincubation not only prevented NMDA-induced phosphorylation of Akt but also decreased to levels below those in control mutant cells ($B_{50\%}$, Figure 7a). NMDA treatment induced a significant increase in p-ERK1/2 levels in both STHdh7/7Q ($B_{50\%}$) and STHdh111/111Q cells ($B_{250\%}$). Similar to that observed for Akt, BDNF pretreatment prevented subsequent NMDA-mediated ERK1/2 phosphorylation independently of p75 NTR transfection. These results indicate that p75NTR/TrkB imbalance disturbs BDNF-mediated neuroprotection against NMDA by reducing Akt phosphorylation.

Reduced Akt phosphorylation in GFP-p75-transfected STHdh111/111Q mutant cells correlates with increased PP1 levels. Akt phosphorylation at Ser-473 can be regulated by the activity of PP1 and PHLPP1 phosphatases. As we observed decreased Akt Ser-473-phosphorylation in GFP-p75 STHdh111/111Q cells after BDNF and NMDA treatment, PP1 and PHLPP1 levels were evaluated. A significant increase in PP1 levels was found in GFP

Figure 7  BDNF prevents NMDA-induced phosphorylation of Akt in GFP-p75 STHdh111/111Q mutant cells. Wild-type (ST7/7Q) and mutant (ST111/111Q) huntingtin striatal cells transfected with GFP or GFP-p75 were treated with BDNF (50 ng/ml, 30 min), NMDA (500 μM, 30 min) or BDNF before addition of NMDA (NMDA + BDNF) for the indicated time periods. Cells were lysed and immunoblots performed to detect Ser-473-Akt (p-Akt) and Akt (a) or phosphoERK1/2 (p-ERK1/2) and ERK1/2 (b). a-tubulin was used as a loading control. The blots are representative of four independent experiments. The histograms represent the relative p-Akt/Akt and p-ERK/ERK ratios considering 100% the ratio obtained in control conditions (vehicle). Values are given as mean ± S.E.M. Data was analyzed by Student’s t-test. $P<0.05$, $++P<0.001$ versus vehicle-treated GFP cells, *$P<0.05$ and $***P<0.001$ versus vehicle-treated GFP-p75 cells, $+$*$P<0.05$, $$$$P<0.001$ NMDA + BDNF-treated GFP mutant cells versus NMDA + BDNF-treated GFP-p75 mutant cells.
(~20%) and GFP-p75 (~30%) STHdh111/111Q cells following NMDA treatment (Figure 8a). Importantly, in GFP-p75 but not in GFP mutant cells incubation with BDNF before NMDA significantly increased PP1 levels (~80% compared with untreated cells and ~50% compared with NMDA-treated cells). No differences on PHLPP1 levels were found between GFP and GFP-p75 mutant cells at any analyzed condition (Supplementary Table 2).

Inhibition of PP1 restores Akt phosphorylation and BDNF neuroprotection in GFP-p75-transfected STHdh111/111Q mutant cells. To confirm a functional role
for PP1 in the lack of BDNF neuroprotection GFP and GFP- 
p75-transfected STHdh111/111Q cells were treated with OA to 
inhibit PP1 activity and p-Akt levels analyzed by western blot 
(Figure 8b). Inhibition of PP1 in GFP-p75 STHdh111/111Q cells 
blocked the reduction of Akt phosphorylation induced by 
BDNF treatment. Moreover and consistent with a detrimental 
role of PP1 on BDNF neuroprotection the cell death of GFP- 
p75 STHdh111/111Q cells induced by BDNF and/or NMDA was 
completely prevented by pretreatment with OA (Figure 8c). 
Altogether, these results support the involvement of PP1 in 
the increased p75-mediated vulnerability of mutant huntingtin 
striatal cells to NMDA excitotoxicity.

Discussion

Several evidences implicate reduced levels of BDNF in HD 
pathology, which has emphasized the study of therapeutic 
strategies based on BDNF administration for HD treatment. 
However, BDNF can also binds to p75NTR, which could either 
potentiate Trk function or signal independently to activate cell 
death cascades. In this study, we found an imbalance between 
p75NTR and TrkB expression in two distinct HD mouse models: HdhQ7/11Q mutant knockin mice and R6/2 
transgenic mice that was also manifest in the putamen of HD 
patients supporting the idea that p75NTR/TrkB imbalance is 
relevant to HD pathology. p75NTR upregulation was 
associated with increased p75NTR mRNA expression, which 
agrees with previous studies showing increased p75NTR and 
reduced TrkB mRNA levels in the caudate of HD patients. 
Deregulation of gene transcription has been implicated in HD 
pathology. In particular upregulation of the transcription factor 
Sp1 has been described in cellular and transgenic models of 
HD suggesting that increased Sp1-mediated transcription 
could contribute to HD pathology. Interestingly, p75NTR 
expression is dependent on binding of Sp1 to the p75NTR 
proximal promoter, which allows us to speculate that 
aberrant Sp1 activity could underlie the upregulation of 
p75NTR mRNA in HD. Our data also demonstrate that 
upregulation of p75NTR protein levels in HD brain follows a 
rostro-caudal gradient with higher p75NTR expression at the 
rostral striatum. Notably, brain tomography studies 

Figure 8 Lack of BDNF neuroprotection against NMDA excitotoxicity is mediated by PP1-induced dephosphorylation of Akt in GFP-p75 STHdh111\111Q mutant cells. Mutant huntingtin (ST111/111Q) striatal cells transfected with GFP or GFP-p75 were incubated with BDNF (50 ng/ml, 30 min), NMDA (500 μM, 30 min) or BDNF before NMDA treatment and cell extracts obtained 15 min later. (a) Representative immunoblot showing the levels of p75NTR and α-tubulin as loading control. The blot is representative of five independent experiments. The histogram represents the relative p75NTR levels considering 100% the value obtained in control conditions (vehicle). Values are given as mean ± S.E.M. Data was analyzed by Student’s t-test. *P<0.05 versus vehicle-treated GFP cells. **P<0.01 versus vehicle-treated GFP-p75 cells. (b) Mutant huntingtin striatal cells (ST111/111Q) transfected with GFP or GFP-p75 were treated with or without OA (200 μM, 30 min) before incubation with BDNF (50 ng/ml, 30 min), NMDA (500 μM, 30 min) or BDNF and NMDA (NMDA + BDNF). Cell extracts were obtained 15 min later and immunoblot performed to detect Ser473-Akt (p-Akt), Akt and α-tubulin as a loading control. The blots are representative of four independent experiments. The histograms represent the relative p-Akt/Akt ratio considering 100% the ratio obtained in control conditions (vehicle). Values are given as mean ± S.E.M. Data was analyzed by Student’s t-test. *P<0.05, **P<0.01 versus vehicle-treated GFP-p75 cells. (c) Mutant huntingtin striatal cells (ST111/111Q) transfected with GFP or GFP-p75 were treated with OA (200 μM, 30 min) before incubation with BDNF (50 ng/ml, 30 min) and then exposed to NMDA (500 μM, 30 min). Cell survival was evaluated 24 h later by scoring the percentage of Hoechst-stained nuclei. Representative photomicrographs of wild-type (ST7/7Q) and mutant (ST111/111Q) huntingtin cells stained with Hoechst showing the number of surviving cells in the different conditions (Control, NMDA, NMDA + BDNF and BDNF). Scale bar, 10 μM. Quantification of surviving cells is shown as the percentage of total cells in control conditions (vehicle). The results are representative of seven independent experiments performed in triplicate and are expressed as the mean ± S.E.M.
Ser/Thr phosphatases. PP2-A dephosphorylates Akt at Thr-308,15 whereas PP1 and PHLP1 at Ser-473.25,27 No changes on PHLP1 levels were found in BDNF/NMDA-treated GFP-p75 mutant huntingtin cells revealing that this phosphatase unlikely contributes to Akt inactivation. By contrast, PP1 levels were significantly increased following BDNF and NMDA treatment suggesting a mechanistic link between PP1 and Akt inactivation. Supporting this view, BDNF/NMDA-induced dephosphorylation of Akt was blocked by inhibition of PP1 by OA treatment. Moreover, we also demonstrate that PP1-mediated dephosphorylation of Akt contributes to mutant huntingtin cell death as inhibition of PP1 prevented BDNF/NMDA-induced cell death of GFP-p75 mutant cells. Interestingly deregulation of PP1 activity in HD mice has been associated with NMDA-mediated striatal cell death36 and NMDA-induced cell death of retinal ganglion cells has been related with PP1-mediated Akt dephosphorylation.29 Altogether, this data suggest that a dysfunctional signaling cross-talk between TrkB, p75NTR and NMDAR could contribute to increase striatal cell vulnerability in HD (Supplementary Figure 3). These results may have important consequences for the potential use of BDNF as a therapeutic agent in HD. Thus, exogenous BDNF administration or pharmacological treatments that raise BDNF levels only ameliorate or partially improve morphological phenotypes or motor and cognitive behavior in different HD mouse models,41–51 which could be related with the dysfunctional signaling of TrkB and p75NTR demonstrated in the present study. In view of these results, a better understanding of the physiological interactions between p75NTR and TrkB in HD would improve the design of new neuroprotective therapies for HD treatment.

Materials and Methods

Chemicals and antibodies. BDNF was obtained from Peprotech EC Ltd (London UK), Okadaic Acid was obtained from Tocris (Minneapolis, MN, USA), NMDA (N-Methyl-D-aspartic acid) from Sigma-Aldrich (St. Louis, MO, USA) and Lipofectamine 2000 was from Invitrogen (Carlsbad, CA, USA); Phospho p44/42 ERK1/2 (Thr202/Tyr204), Phospho-Akt (Ser-473), Phospho-SAPK/JNK (Thr183/Tyr185), total ERK1/2, total Akt and total SAPK/JNK were obtained from Cell Signaling Technology (Beverly, MA, USA). TrkB polyclonal antibody that recognizes the full-length TrkB isoform (sc-7628, C-tail epitope) was obtained from Santa Cruz Biotechnology (Santa Cruz, CA, USA). TrkB monoclonal antibody that recognizes full-length and truncated TrkB isoforms and anti-DARRP32 was purchased from BD Bioscience (San Jose, CA, USA). Anti-p75NTR was obtained from BD Bioscience (San Jose, CA, USA) and wild-type mice using the Total RNA Isolation Nucleospin RNA II Kit (Macherey-Nagel, Düren, Germany). Purified RNA (500 ng) was reverse transcribed using the StrataScript First Strand cDNA Synthesis System (Strategen, Santa Clara, CA, USA). The cDNA was then analyzed by quantitative RT-PCR using the following TaqMan Gene Expression Assays (Applied Biosystems, Foster City, CA, USA): 18S (Hs99999901_s1) and p75 (Mm00446294_m1). RT-PCR was performed in 25 μl of final volume on 96-well plates, in a reaction buffer containing 12.5 μl TaqMan Gene Expression Assays and 20 ng of cDNA. Reactions included 40 cycles of a two-step PCR: 95 °C for 30 s and 60 °C for 1 min, after initial denaturation at 95 °C for 10 min. All quantitative-PCR experiments were performed in duplicate and repeated in at least three independent experiments. To provide negative controls and exclude contamination by genomic DNA, the RT was omitted in the cDNA synthesis step, and the samples were subjected to the PCR reaction in the same manner with each TaqMan Gene Expression Assay. The quantitative-PCR data was quantified using the $C_T$ method.24 To correct for loading differences, the values were normalized according to the level of expression of the housekeeping gene, 18S, within each sample. Its $C_T$ value

Striatal cells were grown at 33 °C in Dulbecco’s modified Eagle’s medium (DMEM; Sigma-Aldrich) supplemented with 10% fetal bovine serum (FBS), 1% streptomycin-penicillin, 2 ml L-glutamine, 1 ml sodium pyruvate and 400 μg/ml G418 (Geneticin; Gibco-BRL, Gaithersburg, MD, USA). Mouse septal neuron × neuroblastoma hybrid SN56 cells (cell line with negligible TrkB expression) and T48 cells (SN56 cells transfected clone expressing TRKb) were created and kindly provided by Dr. Ky6 (Department of Pathology, Emory University School of Medicine, Atlanta). SN56 cells were maintained at 37 °C in DMEM medium containing 1 ml pyruvate and 10% FBS and T48 cells stably transfected with rat TrkB were cultured in the same medium but containing 300 μg/ml G418.

Genetic Huntington’s disease mouse models. Hdh10111 homozygous knockin mice expressing mutant huntingtin with 111 glutamine residues were maintained on a C57BL/6 genetic background.25 Hdh10117 heterozygous males and females were intercrossed to generate age-matched Hdh101111 homozygous and Hdh10117 wild-type littermates. R6/1 transgenic mice (B6CBA background) expressing exon-1 mutant huntingtin with 145 glutamines under the HD human promoter and their wild-type littermates were obtained from Jackson Laboratory (Bar Harbor, ME, USA). The animals were housed with access to food and water ad libitum in a colony room kept at 19–22 °C and 40–60% humidity, under a 12:12 h light/dark cycle. All procedures were performed in compliance with the European Community guidelines for the care and use of the laboratory animals (86/609/EEC), and approved by the local animal care committee of Universitat de Barcelona (404/12) and Generalitat de Catalunya (DAAM5712).

Postmortem brain tissues. Samples of the putamen nucleus from one patient with HD grade 1 (73 years, postmortem intervals of 7 h), nine patients with HD grade 3 and 4 (71, 63, 65, 60, 47, 44, 40, 39, 28 years, postmortem intervals of 4–15 h) and 10 control cases (77, 74, 71, 68, 65, 64, 60, 59, 56, 39 years, postmortem intervals of 4–23 h) were supplied by the Banc de Teixits Neurologics (Servei Cientifico-Tecnics, Universitat de Barcelona, Barcelona, Spain). The Banc de Teixits Neurologics was established to provide human postmortem brains to researchers in Spain taking into due consideration all the ethical guidelines of the latest Declaration of Helsinki. Informed consent was obtained from all subjects under study.

Cell transfection. All DNA constructs were transfected using Lipofectamine 2000 as instructed by the manufacturer. Both wild-type STHdhQ111Q and mutant STHdh101111Q huntingtin striatal cells were transfected at 50% of confluence with human p75 neurotrophin receptor tagged with GFP at the C-terminus (generously provided by Dr. Formaggio, Department of Medicine and Public Health, Section Pharmacology, University of Verona, Italy). As a control condition cells were transfected with GFP vector from Clontech (Palo Alto, CA, USA). Transfection efficiencies were estimated by flow cytometry and are shown in Supplementary Table 1.

Quantitative RT-PCR. Total RNA was isolated from striatum of HD mutant and wild-type mice using the Total RNA Isolation Nucleospin RNA II Kit (Strategen, Santa Clara, CA, USA). The cDNA was then analyzed by quantitative RT-PCR using the following TaqMan Gene Expression Assays (Applied Biosystems, Foster City, CA, USA): 18S (Hs99999901_s1) and p75 (Mm00446294_m1). RT-PCR was performed in 25 μl of final volume on 96-well plates, in a reaction buffer containing 12.5 μl TaqMan Gene Expression Assays and 20 ng of cDNA. Reactions included 40 cycles of a two-step PCR: 95 °C for 30 s and 60 °C for 1 min, after initial denaturation at 95 °C for 10 min. All quantitative-PCR experiments were performed in duplicate and repeated in at least three independent experiments. To provide negative controls and exclude contamination by genomic DNA, the RT was omitted in the cDNA synthesis step, and the samples were subjected to the PCR reaction in the same manner with each TaqMan Gene Expression Assay. The quantitative-PCR data was quantified using the comparative quantitation analysis program of MxPro Q-PCRAnalysis software version 3.0 (Strategen). The $C_T$ value for each reaction, and the relative level of gene expression for each sample were calculated using the $2^{-ΔΔC_T}$ method.24 To correct for loading differences, the values were normalized according to the level of expression of the housekeeping gene, 18S, within each sample. Its $C_T$ value.
was subtracted from that of the specific genes to obtain a ΔCt value. Differences (∆ΔCt) between the ΔCt values obtained for the control mice (calibrators) and the ΔCt values for the R6/1 or the HdhQ111/111 mice were determined. The relative quantitative value was then expressed as 2^(-ΔΔCt), representing the fold change in gene expression normalized to the endogenous control and relative to the calibrators.

Drug treatments of striatal cell lines. All drug treatments were performed 48 h after transfection. To induce NMDA excitotoxicity transfected wild-type STHdhQ7/7 and mutant STHdhQ111/111 Huntington striatal cells were exposed to 500 μM NMDA for 30 min in Locke’s solution (154 mM NaCl, 5.6 mM KCl, 2.3 mM CaO2, 3.6 mM NaHCO3, 5 mM HEPES, 5.6 mM glucose and 10 μM glycine). After NMDA treatment, medium was replaced by fresh DMEM medium containing 2.5% FBS and cell survival was analyzed 24 h later. To analyze the neuroprotective role of BDNF against NMDA-mediated excitotoxicity transfected wild-type and mutant huntingtin striatal cells were treated for 30 min in serum-free DMEM medium containing 50 ng/ml BDNF before NMDA exposure (500 μM, 30 min). After NMDA treatment medium was replaced by fresh DMEM medium containing 2.5% FBS and cell survival was analyzed 24 h post-treatment. To analyze basal BDNF signaling, transfected wild-type and mutant huntingtin striatal cells were placed in DMEM serum-free medium for 3 h and then exposed to BDNF (50 ng/ml) for different time periods, (0, 5 and 15 min). To study BDNF signaling in NMDA-treated conditions transfected wild-type and mutant huntingtin striatal cells were treated with BDNF (50 ng/ml) for 30 min before NMDA incubation (500 μM) and total cell extracts were collected at different time periods (0, 5 and 15 min). To analyze apoptotic cascades (cleaved caspase-3 and phospho-JNK levels), cells were treated with BDNF (50 ng/ml, 30 min) or with BDNF before NMDA exposure (500 μM, 30 min) and cell extracts collected 3 h later. Finally, to test the role of protein phosphotase 1 (PP1) in HD pathology, mutant striatal cells were exposed to 200 μM of the PP1 inhibitor OA (30 min) before BDNF treatment (50 ng/ml, 30 min). After BDNF incubation cells were treated with NMDA (500 μM, 30 min), medium replaced by fresh DMEM medium and PP1 levels analyzed by western blot in total extracts obtained 15 min post-treatment. In parallel experiment cells were fixed with 4% paraformaldehyde and cell survival analyzed 24 h later.

Cell survival. Cell survival of striatal cells was assessed by nuclear DNA staining with Hoechst 33258. Cells were washed twice with PBS, fixed with 4% paraformaldehyde in PBS for 10 min, washed twice in PBS, and stained with Hoechst 33258 (1 μg/ml) for 5 min. Stained cells were then washed twice in PBS and mounted under glass coverslips with Mowiol. Cell survival is represented as the proportion of Hoechst-stained nuclei counted in treated cells compared with the number of control cells (vehicle-treated). Forty fields were counted per condition and experiment, comprising at least 30–40 cells. Data are given as mean ± S.E.M. of values obtained in seven independent experiments performed in triplicate.

AAV-mediated shp75 expression vectors. For knockdown p75NTR expression we designed a shRNA oligomer targeting the mouse p75NTR (Ngfr1) (5’ GAGCGATCATCGAGGAGCG TGA 3’). This shRNA was therefore used to obtain the corresponding shRNA to clone into a rAAV2/8-GFP adenoviral vector (BamHI site and AgeI at the 3’ end). The AAV2/8 plasmids and infectious AAV viral particles containing GFP expression cassette with scrambled shRNA (AAV-shRNAGFP) or p7ShRNA (AAV-shp75GFp) were generated by the Unitat de Producció de Vectors from the Center of Animal Biotechnology and Gene Therapy at the Universitat Autònoma de Barcelona.

Intrastral injection of adenoviral vectors. Seven-months-old wild-type HdhQ7/7 and mutant HdhQ111/111 mice (n = 4–5) were deeply anesthetized with pentobarbital (40–60 mg/kg) and placed in a stereotaxic apparatus for bilateral intrastral injections of rAAV2/8 expressing shp75 or control shRNA (3 μl, 1,53 x 10^12 GC). A small incision was made in the scalp, and the striatum was marked using the following stereotaxic coordinates to Bergman: anteroposterior (AP), + 0.6 mm; mediolateral (ML), + 2 mm; and 2.7 mm below the dorsal surface with the incisor bar at 3 mm above the interaural line. Viral vector was injected using a 10 μl Hamilton microliter syringe at an infusion rate of 0, 5 μl/min; the needle was left in place for 5 min to ensure complete diffusion of the viruses and then slowly retracted from the brain. Four weeks after injections, the mice were killed to obtain corticostriatal organotypic cultures as mentioned below.

Corticostriatal organotypic cultures. Corticostriatal slice cultures were prepared by the interface culture method55 slightly modified. In brief, 8-month-old wild-type HdhQ7/7 and mutant HdhQ111/111 mice were killed by instant decapitation and their brains were quickly removed and placed in a petri dish containing disecting salt medium (MEMp: 50% (vol/vol) MEM, 25 mM HEPES and 2 mM glutamine without antibiotics) under sterile conditions. After removal of the meninges the brains were sectioned coronally (400 μm) by using a McIlwain tissue chopper (Mickle Laboratory, Cambridge, UK). The resulting brain slices were placed in incubation culture medium (MEM: 50% (vol/vol) MEM, 25 mM HEPES, 25% (vol/vol) HBSS, 25% (vol/vol) heat-inactivated horse serum, 2 mM glutamine, 1 ml of penicillin/streptomycin solution and 0.044% (vol/vol) NaHCO3). These slices were then trimmed to include the dorsal one half of the striatum with the overlying frontoparietal neocortex. From each donor mouse an average of seven corticostriatal cultures were obtained using both hemispheres. The slices were stored for 1 h at 4°C before being transferred to 24-well plates contained inserts of humidified porous membranes (0.4 μm Millicell, 12 mm diameter Millipore) in 250 μl of culture medium. The cultures were maintained at 37°C in a 5% CO2/95% air atmosphere at a relative humidity of 95%. Culture viability was first determined by subjective judgment of the transparency, color and border morphology. To validate the method, the viability of our corticostriatal organotypic slice cultures was analyzed using a standardized protocol for PI uptake. Briefly, 2 h after transferring the slices to the transwell, 20 μl of 0.1% PI was added to the organotypic culture. This concentration is kept in the medium during the 24 h period incubation. After 24 h, slices were then incubated (30 min at 37°C) with 0.01% Calcein AM, a cell-permeant dye used to determine cell viability (Molecular Probes Inc, Eugene, OR, USA). Images were analyzed by confocal microscopy.

CCK-8 cytotoxicity assay. Cell viability of corticostriatal slices was assessed by WST-8 assay using the Cell Counting Kit-8 (CCK-8, Sigma-Aldrich, St. Louis, MO, USA), in which colored formazan was formed in viable cells in response to cellular dehydrogenase activity. Briefly, after BDNF treatment (200 ng/ml), 25 μl of Cell Counting Assay Kit-8 solution was added to each corticostriatal slice. After 3 h or 24 h of incubation, 100 μl of medium from each slice culture was dispensed in a 96-well plate and absorbance at 450 nm was measured using a microplate reader. The cell viability was calculated as the ratio between the absorbance measurements at 3 h and 24 h and the results expressed as the percentage of viable cells relative to GFP-vehicle-treated slices (control). Each experiment contained four readings for each experimental condition.

Immunofluorescence. For immunohistochemical analysis, homozygous mutant HdhQ111/111 and wild-type HdhQ7/7 mice at 8 months of age or wild-type and R6/1 mice at 30 weeks of age (n = 3 for each condition) were deeply anesthetized and immediately perfused transcardially with saline (pH 7.4), 4% paraformaldehyde/phosphate buffer. Brains were removed and postfixed in a 10% formalin solution. Cryosections (30 μm) were then washed in PBS and incubated in PBS as free-floating sections. Sections were then transferred three times in PBS, incubated with NH4Cl 50 mM, and permeabilized with PBS containing 0.5% Triton X-100. Blocking was performed with PBS containing 0, 2% BSA and 5% normal goat serum (Fierce Biotechnology, Rockford, IL, USA) for 2 h at room temperature. The sections were then washed in PBS and incubated overnight at 4°C with anti-p75 (1:100), anti-GFAP (1:100), anti-DARPP32 (1:1000) or anti-parvalbumin (1:1250) antibodies and detected with Cy3 anti-rabbit and Cy2 anti-mouse (1:200) secondary antibodies. Following secondary antibody incubation, slices were rinsed in PBS. As negative controls, some sections were processed as described in the absence of primary antibody and no signal was detected. Immunofluorescence was analyzed by confocal microscopy using a TCS SL laser scanning confocal spectral microscope (Leica Microsystems Heidelberg GmbH, Mannheim, Germany). For human brain immunofluorescence analysis, paraffin sections of the putamen nucleus from one patient with HD grade 1 (73 years, 7 h postmortem) was supplied by the Banc de Teixits Neurologics (Servei Cientı´fico-Te`cnics, Universitat de Barcelona, Barcelona, Spain). Paraffin sections were dewaxed and rehydrated using a xylene/ethanol series followed by rinsing with PBS. Heat-induced epitope retrieval was performed in citrate buffer, pH 6.0 (DAKO) for 20 min. Sections were then rinsed three times in PBS, incubated with NH4Cl 50 mM, and permeabilized with PBS containing 0.2% Triton X-100 for 45 min. Blocking was performed with PBS containing 1% BSA and 10% normal horse serum (Fierce) for 1 h at room temperature.
temperature. After washing sections were incubated overnight at 4 °C with anti-p75 (1:100), and anti-DARPP32 (1:100) diluted in blocking buffer and detected with Alexa Fluor 488 Goat anti-Rabbit IgG Conjugate (green) and Cy3 anti-mouse (1:200) secondary antibodies. Following secondary antibody incubation, slices were rinsed in PBS. As negative controls, some sections were processed as described in the absence of primary antibody and no signal was detected. Immunofluorescence was analyzed by confocal microscopy using a Leica TCS SP5 laser scanning spectral confocal microscope (Leica) with Argon and HeNe lasers attached to a Leica DMi6000 inverted microscope.

Image analysis of striatal coronal sections. Coronal sections spaced 240 µm apart comprising rostral, middle and caudal levels of the striatum (1.54 mm to −0.7 mm from Bergman) from wild-type and R6/1 mice (n = 3) were examined with Leica TCS SP5 laser scanning spectral confocal microscope. Images were transferred to nitrocellulose membranes (Schleicher & Schuell, Keene, NH, USA). Protein extracts (30 µg) were mixed with 4X SDS sample buffer, boiled for 5 min, resolved by 8–12% SDS-polyacrylamide gel electrophoresis and transferred to nitrocellulose membranes (Schleicher & Schuell, Keene, NH, USA). The membranes were then incubated overnight at 4 °C with primary antibodies: TrkB polyclonal antibody (1:500; cellular extracts), TrkB monoclonal antibody (1:1000, striatal extracts), p75 antibody (1:1000), anti-NeuN (1:1000), anti-GFP (1:1000), anti-GFP rabbit antibody (1:500), Phospho p44/42 ERK1/2 (Thr202/Tyr204) (1:1000), Phospho-Akt (Ser473) (1:1000), Phospho-SAPK/JNK (Thr183/Tyr185) (1:1000), total ERK1/2 (1:2500), total Akt (1:1000), SAPK/JNK (1:1000), α-tubulin (1:50 000) or β-actin (1:20 000). The membranes were then rinsed three times with Tris-buffered saline Tween-20 (TBS-T) and incubated with horseradish peroxidase-conjugated secondary antibody for 1 h at room temperature. After washing for 30 min with TBS-T, the membranes were developed using the enhanced chemiluminescence substrate kit (Santa Cruz Biotechnology). The Gel-Pro densitometry program (Gel-Pro Analyzer for Windows- version 4.0.00.001) was used to quantify the different immunoreactive bands relative to the intensity of the α-tubulin or actin band in the same membranes. Data are expressed as the mean ± S.E.M. of band density obtained in independent experiments or samples.

Statistical analysis. All of the data were analyzed with the program GraphPad Prism version 4.0 (GraphPad Software, La Jolla, CA, USA). Results are expressed as mean ± S.E.M. Experimental data were analyzed either by a one- or two-way ANOVA followed by the post hoc Bonferroni’s multiple comparison test or by Student’s t-test. A value of P<0.05 was accepted as denoting statistical significant differences.

Conflict of Interest
The author declares no conflict of interest.

Acknowledgements. The authors thank M Macdonald for providing the huntingtin knock-in striatal cell lines. The authors thank Dr. Formaggio for providing human p75 neurotrophin receptor tagged with GFP at the C-termius and Dr. K Ye for providing SN56 cells and T48 cells. We are very grateful to Ana Lopez and Maria Teresa Muñoz for technical assistance and Dr. Teresa Rodrigo and the staff of the animal care facility (Facultad de Psicología, Universitat de Barcelona) for their help. We are grateful to the University of Barcelona and the Institute of Neuropathology Brain Banks (Barcelona, Spain) for providing brain samples from control subjects and HD patients. We thank members of our laboratory for helpful discussion.
