Abstract

A new species of the genus *Gracixalus*, *Gracixalus yunnanensis* sp. n., is described based on a series of specimens collected from southwestern and southern Yunnan, China. This species is distinguished from all other known congeners by a combination of the following characters: relatively small body size in adult males (SVL 26.0–34.2 mm); dorsal surface yellow brown or red brown; distinctive conical asperities on dorsum; males with an external subgular vocal sac and linea masculina; throat, chest, and belly nearly immaculate; venter surface orangish with yellow spots, semi-transparent; snout rounded; supratympanic fold distinct; iris bronze; lack of white patch on temporal region; tibiotarsal projection absent; sides of body nearly smooth with no black blotch; finger webbing rudimentary; and toe webbing formula I1.5–2II1.5–2.7III.5–3IV2.5–1.5V. Genetically, the new species diverges from its congeners by 2.2%–14.1% (uncorrected p-distance) and is closest to *G. guangdongensis*. However, the new species can morphologically be separated from *G. guangdongensis* by distinctive conical tubercles on dorsum (versus absent), lateral surface nearly smooth with no black blotches on ventrolateral region (versus absent), lateral surface nearly smooth with no black blotches on ventrolateral region (versus lateral surface rough, scattered with tubercles and black blotches on ventrolateral region), snout rounded (versus triangularly pointed), iris bronze (versus iris brown), and ventral surface orangish (versus throat and chest creamy white and belly light brown).

Introduction

The genus *Gracixalus* Delorme, Dubois, Grosjean & Ohler, 2005 is known from southern and southwestern China, Vietnam, Laos, Thailand, and Myanmar and contains 16 species including *G. ananjevae* (Matsui & Orlov, 2004), *G. carinensis* (Boulenger, 1893), *G. gracilipes* (Bourret, 1937), *G. guangdongensis* Wang, Zeng, Liu & Wang, 2018, *G. jinggangensis* Zeng, Zhao, Chen, Chen, Zhang & Wang, 2017, *G. jinxiuensis* (Hu, in Hu et al. 1978), *G. lumarius* Rowley, Le, Dau, Hoang & Cao, 2014, *G. medogensis* (Ye & Hu, 1984), *G. nonggangensis* Mo, Zhang, Luo, Zhou & Chen, 2013, *G. quangi* Rowley, Dau, Nguyen, Cao & Nguyen, 2011, *G. quyeti* (Nguyen, Hendrix, Bohme, Vu & Ziegler, 2008), *G. sapaensis* Matsui, Ohler, Eto & Nguyen, 2017, *G. seesom* Matsui, Khonsue, Panha & Eto, 2015, *G. supercornutus* (Orlov, Ho & Nguyen, 2004), *G. tianlinensis* Chen, Bei, Liao, Zhou & Mo, 2018, and *G. waza* Nguyen, Le, Pham, Nguyen, Bonkowski & Ziegler, 2013 (Frost 2018). Of the 16 members of *Gracixalus*, ten were discovered in last decade (Nguyen et al. 2008, Rowley et al. 2011, Mo et al. 2013, Nguyen et al. 2013, Rowley et al. 2014, Matsui et al. 2015, Matsui et al. 2017, Zeng et al. 2017, Chen et al. 2018, Wang et al. 2018), indicating that species diversity of *Gracixalus* was very poorly understood in the past. Moreover, recent phylogenetic analyses (Matsui et al. 2017, Chen et al. 2018) showed that there are still several unnamed distinct lineages in the group of *G. jinxiuensis*, indicating that species richness of *Gracixalus* remains underestimated.

During recent fieldworks in Yunnan, China, we collected some specimens of a small-sized tree frog, which morphologically can be assigned to the genus *Gracixalus* by the presence of intercalary cartilage between terminal and penultimate phalanges of digits, tips of digits enlarged to discs bearing circummarginal grooves, vomerine teeth absent, inner (first and second) and outer (third and fourth) fingers non-opposable, and an inversed Y-shaped dark brown marking on dorsum (Fei 1999, Rowley et al. 2011, Chen et al. 2018), but morphologically and genetically can be distinguished from all recognized species of genus *Gracixalus*. Thus, we describe these specimens as a new species of *Gracixalus*.

Materials and methods

Sampling

Specimens were collected during fieldworks in Menghai County, Lancang County, and Luchun County of Yunnan, China in 2014 to 2018 (Fig. 1). They were fixed and then
A new species of Gracixalus (Anura, Rhacophoridae) from Yunnan, China

Figure 1. Map showing collection sites of *Gracixalus yunnanensis* sp. n. Star indicates the type locality (Xuelin) and circles indicate Fudong Township (1), Fazhanhe Township (2), Bada Township (3), Mt. Huanglian (4), Jinping (5), Lao Cai (6), Nghe An (7), and Houapan (8), respectively. Sequences of samples from sites 5–8 came from previous studies.

Specimens were deposited at the Kunming Institute of Zoology (KIZ), Chinese Academy of Sciences and Guangxi Normal University (GXNU).

**Morphology**

Morphometric data were taken using digital calipers to the nearest 0.1 mm. Morphological terminologies follow Matsui et al. (2017) and Wang et al. (2018). Measurements include:

- **SVL**: snout-vent length (from tip of snout to vent);
- **HL**: head length (from tip of snout to rear of jaws);
- **HW**: head width (width of head at its widest point);
- **SL**: snout length (from tip of snout to anterior border of eye);
- **IND**: internarial distance (distance between nares);
- **IOD**: interorbital distance (minimum distance between upper eyelids);

Specimens were stored in 80% ethanol after taking photos. Liver tissues were preserved in 99% ethanol.
Comparative morphological data of other *Gracixalus* species were taken from their original descriptions or re-descriptions (Boulenger 1893, Hu et al. 1981, Ye and Hu 1984, Matsui and Orlov 2004, Orlov et al. 2004, Nguyen et al. 2008, Rowley et al. 2011, Mo et al. 2013, Nguyen et al. 2013, Rowley et al. 2014, Matsui et al. 2015, Matsui et al. 2017, Zeng et al. 2017, Chen et al. 2018, Wang et al. 2018).

**Molecular analyses**

Total genomic DNA was extracted from liver tissues. Tissue samples were digested using proteinase K, and subsequently purified following a standard phenol/chloroform isolation and ethanol precipitation. A fragment encoding partial 16S rRNA gene was amplified and sequenced following Yu et al. (2010). All new sequences have been deposited in GenBank under Accession Nos. MK234876–MK234883 (Table 1). Available homologous sequences of *Gracixalus* were obtained from GenBank. *Rhacophorus borneensis* Matsui, Shimada & Sudin, 2013 and *Kurixalus idiootocus* (Kuramoto & Wang, 1987) were selected as outgroups according to Matsui et al. (2017) and sequences of them were also downloaded from GenBank.

Sequences were aligned using MUSCLE with the default parameters in MEGA version 7 (Kumar et al. 2016). Uncorrected pairwise distances between species were calculated in MEGA version 7. The best substitution model was selected using the corrected Akaike Information Criterion (AICC) in jMODELTEST version 2.1.10 (Darriba et al. 2012). Three methods were used to construct phylogeny of the genus *Gracixalus*. Firstly, Bayesian inference (BI) was performed in MRBAYES version 3.2.6 (Ronquist et al. 2012) based on the selected substitution model (TIM2 + I + G). Two runs were performed simultaneously with four Markov chains starting from random tree. The chains were run for 5,000,000 generations and sampled every 100 generations. Convergence and burn-in were checked using the program Tracer version 1.6. (Rambaut et al. 2014) and plot of the generation versus the log likelihood values. The first 25% of the sampled trees were discarded as burn-in and the remaining trees were used to create a consensus tree and to estimate Bayesian posterior probabilities (BPPs). Secondly, maximum likelihood (ML) analysis was conducted in RAXML-HPC version 8.2.10 (Stamatakis 2014) with 1000 rapid bootstrap replicates. Finally, a neighbor-joining (NJ) tree was constructed using PAUP* version 4.0b10 (Swofford 2002) and nodal supports were assessed by 1000 bootstrap replicates.
**Table 1.** Species used in phylogenetic analysis of this study.

Results

The obtained alignment of 16S rRNA sequences is 543 bp in length after cutting off both ragged sides. The newly collected samples from Bada, Xuelin, Fudong, Fazhanhe, and Lvchun of Yunnan, China form a distinct lineage together with samples from Houapan of Laos (KUHE 32453), Nghe An (AMS R173454) and Lao Cai (VNMN 4355, 4357, 4371) of Vietnam, and Jinping of Yunnan (KIZ 060821126) that were sequenced by previous studies (Yu et al. 2008, Rowley et al. 2011, Matsui et al. 2015, Matsui et al. 2017) (Figs 2, 3). Both Bayesian inference and Maximum likelihood analyses recovered this lineage as the sister to the clade consisting of *G. ananjevae* and *Gracixalus* sp. (GQ285669) with weak support (Fig. 2), whereas the NJ analysis revealed that it is closest to *G. guangdongensis* with weak support (Fig. 3). Average uncorrected pairwise distances (p-distance) between the new species and other species ranged from 2.2% (*G. guangdongensis*) to 14.1% (*G. lumarius*) (Table 2).

Morphologically, these newly collected specimens can be distinguished from *G. guangdongensis* by a series of characters, including distinctive conical tubercles on dorsum (versus absent), lateral surfaces nearly smooth with no black blotches on ventrolateral region (versus lateral surfaces rough, scattered with tubercles and black blotches on ventrolateral region), snout rounded (versus triangularly pointed), iris bronze (versus iris brown), and ventral surface orangish (versus throat and chest creamy white and belly light brown). These specimens also differ from other members of *Gracixalus* in a series of characters. Herein we describe these specimens as a new species.

### Table 2. Uncorrected p-distances (%) between *Gracixalus* species estimated from 16S rRNA sequences.

| Species                    | 1       | 2       | 3       | 4       | 5       | 6       | 7       | 8       | 9       | 10      | 11      | 12      | 13      | 14      | 15      | 16      |

Figure 3. Neighbor-joining (NJ) tree of *Gracixalus* inferred from 543 bp of 16S rRNA gene. Numbers above branches are bootstrap values (only values above 50% are shown).
Gracixalus yunnanensis sp. n.
http://zoobank.org/1D19A62E-B4B2-4EDA-975D-4DCFD58DEDAD
Figs 4–6

**Type material.** **Holotype.** KIZ 20160222, an adult male, collected at 21:05 on 1 June 2017 by Hong Hui from Xuelin Township, Lancang County, Yunnan Province, China (23°0’39.4"N, 99°31’54"E, 1864 m elevation).

**Paratypes.** Seven adult males: KIZ 20160223 collected at 21:05 on 1 June 2017 by Hong Hui from the type locality; KIZ 20160216 collected at 21:00 on 7 June 2014 by Hong Hui from Bada Township, Menghai County, Yunnan Province, China (21°50’8.9"N, 100°6’57.8"E, 1870 m elevation); KIZ 20160226 collected at 21:50 on 27 May 2017 by Hong Hui from Fudong Township, Lancang County, Yunnan Province, China (23°7’13.6"N, 99°58’33.9"E, 2166 m elevation); KIZ 20160228–20160230 collected at 21:40–22:15 on 10 June 2017 by Hong Hui from Fazhanhe Township, Lancang County, Yunnan Province, China (22°24’3.4"N, 100°12’4.2"E, 1822 m elevation); and GXNU YU000060 collected at 21:00 on 7 June 2018 by Jian Wang from Mt. Huanglian, Lvchun County, Yunnan Province, China (22°53’N, 102°18’E, 1918 m elevation).

**Etymology.** The specific epithet *yunnanensis* refers to the distribution of this species in China, Yunnan Province.

**Diagnosis.** The new species is assigned to genus *Gracixalus* based upon molecular data and the following morphological characters: the presence of intercalary cartilage between terminal and penultimate phalanges of digits, tips of digits enlarged to discs bearing circummarginal grooves, vomerine teeth absent, inner (first and second) and outer (third and fourth) fingers non-opposable, and an inverted Y-shaped dark brown marking on dorsum (Fei 1999, Rowley et al. 2011, Chen et al. 2018). The new species is distinguished from its congeners by a combination of 1) SVL 26.0–34.2 mm in males; 2) dorsal surface yellow brown or red brown; 3) distinctive conical tubercles on dorsum; 4) males with an external subgular vocal sac; 5) throat granular; 6) finger webbing rudimentary; 7) linea masculina, a band of connective tissue between the rectus abdominus muscle and oblique abdominus muscle, present in males; 8) tibiotarsal articulation reaching eye; 9) snout rounded; 10) white patch absent on temporal region; 11) tibiotarsal projection absent; 12) supratympanic fold distinct; 13) ventral surface orangish, nearly immaculate, and semi-transparent; 14) nuptial pads present on finger I; 15) heels overlapping when legs at right angle to body; 16) iris bronze; and 17) body sides nearly smooth with no black blotch.

**Description of holotype.** Adult male (SVL 29.7 mm); head wider (HW 10.9 mm) than long (HL 9.5 mm); snout rounded, slightly projecting beyond margin of lower jaw in ventral view, rounded in profile; canthus rostralis rounded; loreal region oblique, slightly concave; nostril oval, protuberant, closer to tip of snout than eye; IND (2.9 mm) slightly narrower than IOD (3.0 mm) and wider than UEW (2.5 mm); eye large, horizontal diameter (ED 4.2 mm) equal to snout length (SL 4.2 mm); pupil oval, horizontal; pineal ocellus absent; tympanum distinct, diameter (TD 1.5 mm)
smaller than half of ED; supratympanic fold distinct, extending from posterior corner of eye to above insertion of arm; vomerine teeth absent; tongue notched posteriorly; a pair of vocal sac slits on floor of mouth at both corners; an external subgular vocal sac.

Forelimb relatively robust; length of forearm and hand (FHL 14.1 mm) 47% of SVL; relative length of fingers I < II < IV < III; tips of all fingers expanded into discs with circummarginal grooves; disc of third finger large, slightly wider than tympanum; nuptial pads present on base of finger I; webbing between fingers rudimentary; subarticular tubercles prominent, rounded, single, formula 1, 1, 2, 2; supernumerary tubercles present; an inner metacarpal tubercle, oval; one outer metacarpal tubercle, rounded.

Heels overlapping when legs at right angle to body; tibiotarsal articulation reaching to middle of eye when hindlimb adpressed to body; relative length of toes I < II < III < V < IV; tips of toes expanded into discs with circummarginal grooves; discs of toes smaller than those of fingers; toes webbed, webbing formula I1.5–2II1.5–2.7III.5–3IV2.5–1.5V following Savage (1975); subarticular tubercles distinct and rounded, formula 1, 1, 2, 3, 2; supernumerary tubercles present; inner metatarsal tubercle oval; outer metatarsal tubercle absent.

Dorsal surface scattered with many small conical tubercles on head, upper eyelids, and dorsum; flanks of body and dorsal surface of limbs smooth, few small conical tubercles on hindlimbs and forearms; throat, chest, belly, and venter of thigh granulated; few small conical tubercles scattered on venter of thigh, tibia, and forearm.

**Coloration of holotype.** In life, iris bronze; dorsal surface yellow brown with a dark brownish Y-shaped marking across back, covering interorbital region and posterior eyelids, bifurcating into two branches on the shoulder, and reaching the posterior of the back; limbs dorsally brown with dark brown bars; sides of head faint brown; flanks yellow brown, mottled with faint pink on lower part; minute dark spots densely scattered on lower part of flanks, temporal region, and upper jaw; skin of ventral surface semi-transparent, orangish with yellow spots; nuptial pads and discs faint yellow; linea masculina visible, white (Fig. 4b).

In preservative, color faded, pattern same as in life. Dorsal surface grayish brown, with a darker brown Y-shaped marking; dorsal side of limbs barred with dark brown; ventral surface of throat, chest, belly, forelimbs, and hindlimbs faded to whitish.

**Morphological variation.** Measurements are shown in Table 3. Because the holotype and paratypes of the new species are all male, sexual dimorphism could not be determined. IOD is slightly wider than IND in holotype and most paratypes with the exception of KIZ 20160228, and TL is longer than FL in holotype and most paratypes with exceptions of KIZ 20160226 and KIZ 20160229.

Color of dorsal and ventral surfaces varied among individuals. Dorsal ground color of the holotype and four paratypes (KIZ 20160216, KIZ 20160223, KIZ 20160228, and KIZ 20160230) is yellow brown, and dorsal ground color of remaining paratypes (KIZ 20160226, KIZ 20160229, and GXNU YU000060) is red brown. Ventral surface of all specimens is nearly immaculate with the exception of paratype GXNU YU000060, which has dark marbling on throat, chest, and belly (Fig. 6). Conical tubercles on dorsum of specimens with red brown ground color are more distinct visually (Fig. 6).
A new species of Gracixalus (Anura, Rhacophoridae) from Yunnan, China

Distribution. In China, the new species is known from Yunnan (Lancang County, Menghai County, Lvchun County, and Jinping County). In addition, the new species also occurs in Laos (Houapan) and Vietnam (Lao Cai and Nghe An) because our molecular analyses revealed that samples from Houapan (KUHE 32453), Lao Cai (VNMN 4355, 4357, 4371), and Nghe An (AMS R173454) that were sequenced by previous studies also belong to the new species (Figs 2, 3). In Yunnan, specimens were found sitting on leaves of herbaceous plants (e.g., Amomum tsaoko and Eupatorium adenophorum). No eggs and tadpoles were found.

Comparisons. A summary of morphological comparisons presents in Table 4. The new species can be distinguished from G. ananjevae by having distinctive conical tubercles on dorsum (versus absent), sides of body smooth (versus coarsely granular), skin of throat granular (versus plain), and snout rounded (versus slightly pointed);

no black blotches on ventrolateral region (versus flanks rough, scattered with tubercles and black blotches on ventrolateral region), snout rounded (versus triangularly pointed), ventral surface orangish (versus throat and chest creamy white and belly light brown), and iris bronze (versus iris brown).

*Gracixalus yunnanensis* sp. n. differs from *G. jinggangensis* by having distinctive conical tubercles on dorsum (versus absent), flanks nearly smooth (versus rough with tubercles), snout rounded (versus triangularly pointed), ventral surface orangish and immaculate (versus throat and chest dirty white with dark specks, belly white anteriorly with dark marking and posteriorly yellowish), nuptial pads present only on finger I (versus nuptial pads present on fingers I and II), heels overlapping when hindlimbs held at right angles to the body (versus just meeting), and iris bronze (versus iris golden); from *G. jinxiuensis* by larger body size in males (SVL 26.0–34.2 mm versus 23.5–26.3 mm), males with an external vocal sac (versus vocal sac internal), flanks nearly smooth (versus rough with tubercles), linea masculina present (versus absent), ventral surface orangish and immaculate (versus ventral surface gray-brown with dark marbling), and sole of feet and palms smooth (versus rough with dense large tubercles); and from *G. lumarius* by smaller body size in males (SVL 26.0–34.2 mm versus 38.9–41.6 mm), dorsal surface yellow brown or red brown (versus yellow), and venter orangish and semi-transparent (versus venter opaque pink), supratympanic fold distinct (versus indistinct), and iris bronze (versus dark gold).

*Gracixalus yunnanensis* sp. n. can be distinguished from *G. medogensis* by having distinctive conical tubercles on dorsum (versus absent), dorsal surface yellow brown or red brown (versus grass green), males with an external vocal sac (versus an internal vocal sac), finger webbing rudimentary (versus absent), and venter orangish (versus pale green); from *G. nonggangensis* by having conical tubercles on dorsum (versus absent), dorsum yellow brown or red brown with a dark brown marking (versus yellowish-olive with a dark-green marking), males with an external vocal sac (versus internal), flanks smooth (versus rough with tubercles), finger webbing rudimentary (versus absent), linea masculina present in males (versus absent), tibiotarsal articulation reaching to eye (versus reaching to tip of snout), ventral surface immaculate (versus throat, chest, and belly white with dark marbling), nuptial pads present on finger I (versus absent), and iris bronze (versus olive); from *G. quangi* by having bigger body size in males (SVL 26.0–34.2 mm versus < 25 mm), dorsal surface yellow brown or red brown (versus olive-green), black spots absent on flanks and ventral surface of thighs (versus present), throat granular (versus smooth), finger webbing rudimentary (versus absent), snout rounded (versus triangular pointed), white patch absent on temporal region (versus present), tibiotarsal projection absent (versus present), and ventral surface orangish (versus opaque white with translucent pale green margins); and from *G. quyeti* by dorsal surface yellow brown or red brown (versus brownish to moss-green), flanks nearly smooth (versus rough with sharp tubercles), throat granular (versus smooth), tibiotarsal articulation reaching to eye (versus reaching to snout), supratympanic fold distinct (versus indistinct), and throat and chest immaculate (versus throat, margin of throat, and chest yellow-white with brown marbling).
A new species of Gracixalus (Anura, Rhacophoridae) from Yunnan, China

Gracixalus yunnanensis sp. n. differs from G. sapaensis by having distinctive conical tubercles on dorsum (versus absent) and sides of body nearly smooth (versus coarsely scattered with large round tubercles); from G. seesom by bigger body size in males (SVL 26.0–34.2 mm versus 21.6–23.0 mm), conical tubercles present on dorsum (versus absent), dorsal surface yellow brown or red brown (versus tan), flanks nearly smooth with no white blotches (versus flanks with large tubercles and white blotches), throat granular (versus smooth), snout rounded (versus triangular pointed), nuptial pads present on finger I (versus absent), and iris bronze (versus golden); and from G. supercornutus by bigger body size in males (SVL 26.0–34.2 mm versus 22.0–24.1 mm), conical tubercles on dorsum small (versus considerable bigger horn-like projections in supraorbital area, around cloaca, and on dorsal surface, forelimbs and hindlimbs), dorsal surface yellow brown or red brown (versus greenish), snout rounded (versus triangular pointed), white patch absent on temporal region (versus present), and tibiotarsal projection absent (versus present).

The new species can be distinguished from G. tianlinensis by smaller body size in males (SVL 26.0–34.2 mm versus 30.3–35.9 mm), distinctive conical tubercles present on dorsum (versus absent), dorsal surface yellow brown or red brown (versus brown to beige), finger webbing rudimentary (versus absent), ventral surface orangish, immaculate, and semi-transparent (versus throat and chest gray with dark specks and belly creamy white, opaque), and nuptial pads present on finger I (versus on fingers I and II); and from G. waza by having distinctive conical tubercles on dorsum (versus absent), dorsal surface yellow brown or red brown (versus greyish-green to moss-green), throat granular (versus smooth), finger webbing rudimentary (versus absent), and ventral surface immaculate (versus throat and chest with dark marbling).

Discussion

Although G. yunnanensis sp. n. only diverges from G. guangdongensis by a distance of 2.2%, it can be morphologically separated from G. guangdongensis by a series of characters including distinctive conical tubercles on dorsum (versus absent), dorsal surface yellow brown or red brown (versus brown to beige), finger webbing rudimentary (versus absent), ventral surface orangish, immaculate, and semi-transparent (versus throat and chest gray with dark specks and belly creamy white, opaque), and nuptial pads present on finger I (versus on fingers I and II); and from G. waza by having distinctive conical tubercles on dorsum (versus absent), dorsal surface yellow brown or red brown (versus greyish-green to moss-green), throat granular (versus smooth), finger webbing rudimentary (versus absent), and ventral surface immaculate (versus throat and chest with dark marbling).
Historically, *G. yunnanensis* sp. n. was once confused with *G. jinxiuensis* in that the Jinping specimen (KIZ 060821126), Houapan specimen (KUHE 32453), Nghe An specimen (AMS R173454), and Lao Cai specimens (VNMN 4355, 4357, 4371) were originally identified as *G. jinxiuensis* by Yu et al. (2008), Matsui et al. (2015), Rowley et al. (2011), and Matsui et al. (2017), respectively. However, the new species can easily be distinguished from *G. jinxiuensis* by having bigger body size, an external vocal sac, and linea masculina in males (Table 4).

*Gracixalus* now contains a total of 17 species and our phylogenetic analyses revealed that this genus consists of three major clades, one consisting of *G. lumarius* (Clade I), one consisting of *G. seesom, G. quyeti, G. quangi*, *G. supercornutus*, and *G. gracilipes* (Clade II), and one consisting of all other species (Clade III) (Figs 2, 3). This result is consistent with Zeng et al. (2017), Chen et al. (2018), and Wang et al. (2018). However, like these previous studies, the present study did not achieve a complete resolution of phylogenetic relationships among these three clades and phylogenetic relationships within clades II and III. Thus, more studies will be needed to resolve the phylogenetic relationships among this genus. Additionally, taxonomic confusions still exist in *Gracixalus*: Matsui et al. (2015) and Wang et al. (2018) considered that *G. nonggangensis* should be synonymized with *G. waza* because of low genetic distance between them. However, morphologically, males of *G. waza* have developed nuptial pads on finger I according to Nguyen et al. (2013), whereas males of *G. nonggangensis* lack nuptial pad according to Mo et al. (2013). If indeed this is the case, we would

---

prefer that *G. nonggangensis* and *G. waza* represent two different species. Furthermore, cryptic species might exist in *G. nonggangensis* because its monophyly was not supported in Matsui et al. (2015) and Wang et al. (2018). In addition, studies will be necessary to confirm whether the specimen from Wenshan, Yunnan, China (voucher number: 03320Rao; GenBank accession no.: GQ285669) belongs to *G. ananjevae* or not. We found that they are sister to each other with strong support values (Figs 2, 3), which is consistent with Mo et al. (2013); the genetic distance between them is moderate (2.3%; Table 2).

**Acknowledgements**

We thank Tan He and Wenjing Jiang for their assistances with fieldworks. Thanks also to the three reviewers for their helpful comments on the manuscript. This work was supported by the National Natural Science Foundation of China (Nos. 31872212 and 31301870) and CAS “Light of West China” Program to Guohua Yu.
