THE WEIGHT IN A SERRE-TYPE CONJECTURE FOR TAME $n$-DIMENSIONAL GALOIS REPRESENTATIONS

FLORIAN HERZIG

ABSTRACT. We formulate a Serre-type conjecture for $n$-dimensional Galois representations that are tamely ramified at $p$. The weights are predicted using a representation-theoretic recipe. For $n = 3$ some of these weights were not predicted by the previous conjecture of Ash, Doud, Pollack, and Sinnott. Computational evidence for these extra weights is provided by calculations of Doud and Pollack. We obtain theoretical evidence for $n = 4$ using automorphic inductions of Hecke characters.

1. Introduction

Serre conjectured in 1973 that every two-dimensional irreducible, odd Galois representation $\rho : \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \to GL_2(\mathbb{F}_p)$ arises from a modular eigenform. He later predicted that some such eigenform occurs in level $\Gamma_1(N^2(\rho))$ with weight $k^2(\rho)$, where $N^2(\rho)$ is a prime-to-$p$ integer measuring the ramification of $\rho$ outside $p$, whereas $k^2(\rho) \geq 2$ was defined by Serre in terms of the restriction of $\rho$ to an inertia subgroup $I_p$ at $p$ using an essentially combinatorial recipe [Ser87]. This conjecture was finally proven by Khare-Wintenberger [KWa], [KWb].

In this paper we consider $n$-dimensional irreducible, odd Galois representations

$$\rho : \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \to GL_n(\mathbb{F}_p)$$

(for “odd” see (6.6)). Ash, Doud, Pollack, and Sinnott [AS00], [ADP02] conjectured that such $\rho$ arise in the mod $p$ group cohomology of $\Gamma_1(N^2(\rho)) \leq SL_n(\mathbb{Z})$, where $N^2(\rho)$ is the analogue of the above. Eigenvectors in mod $p$ cohomology under a natural Hecke action are the analogues of mod $p$ modular eigenforms, with the coefficients playing the role of the weight. The basic set of (“coefficient”) weights, the so-called Serre weights, are the irreducible representations of $GL_n(\mathbb{F}_p)$ over $\mathbb{F}_p$ with $\Gamma_1(N^2(\rho))$ acting via reduction mod $p$. It is thus desirable to describe the set of Serre weights in which $\rho$ arises. This actually provides finer information than $k^2(\rho)$ when $n = 2$. For us it will be more convenient to let $W(\rho)$ be the set of “regular” Serre weights (up to twisting this corresponds to excluding $p + 1$ among weights $2 \leq k \leq p + 1$ when $n = 2$) in which $\rho$ arises in some prime-to-$p$ level $N$ (i.e., not just $N = N^2(\rho)$; this is not expected to yield any further weights, just as when $n = 2$).
To state our Serre-type conjecture for the weights $W(\rho)$ of $\rho$, we define a (Deligne-Lusztig) representation $V(\rho|_{I_p})$ of $GL_n(\mathbb{F}_p)$ over $\overline{\mathbb{Q}}_p$ and an operator $R$ on the set of Serre weights. By $\overline{V(\rho|_{I_p})}$ we denote the reduction of a $GL_n(\mathbb{F}_p)$-stable $\mathbb{Z}_p$-lattice inside $V(\rho|_{I_p})$ modulo the maximal ideal and let $JH(-)$ denote the set of Jordan-Hölder factors of a composition series.

**Conjecture 1.1.** Suppose that $\rho: \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \to GL_n(\mathbb{F}_p)$ is tamely ramified at $p$. Then $W(\rho) = R(JH(\overline{V(\rho|_{I_p})})).$

Let us denote this conjectural weight set by $W^?(\rho|_{I_p})$, noting that it only depends on $\rho|_{I_p}$. When $\rho$ is no longer tamely ramified at $p$, i.e., $\rho|_{I_p}$ no longer semisimple, one expects that $\emptyset \neq W(\rho) \subset W^?(\rho|_{ss,I_p})$.

When $n = 3$ and $\rho|_{I_p}$ is tame, $W^?(\rho|_{I_p})$ contains the set of regular Serre weights specified in [ADP02] (strictly in most cases); see thm. 7.9. The set of all Serre weights is essentially the disjoint union of two subsets (according to the “alcoves” in the representation theory of algebraic groups in characteristic $p$) that are interchanged by $R$. If $\rho|_{I_p}$ is moreover generic, $W^?(\rho|_{I_p})$ consists of 9 weights, 3 lying in the lowest alcove and 6 lying in the other, regardless of what fundamental tame characters $\rho|_{I_p}$ involves (there are three possibilities). Note that the proportion of tame $\rho|_{I_p}$ that are generic tends to 1 as $p$ tends to infinity; for a precise definition of “generic”, see (6.25). For any $n$ we obtain an explicit description of $W^?(\rho|_{I_p})$ for generic tame $\rho|_{I_p}$ in terms of the geometry of alcoves, using results of Jantzen [Jan81], [Jan05] on the decomposition of Deligne-Lusztig representations. Roughly, $W^?(\rho|_{I_p})$ consists of $n!$ weights, $n$ to an alcove, together with certain higher translates. (The latter dominate once $n \geq 4$.)

The evidence we obtain for the conjecture is of two kinds. First, when $n = 3$, Doud and Pollack independently verified for us computationally (up to convincing bounds) for several explicit, tame $\rho$ (taken mostly from [ADP02]) that $W(\rho)$ contains those weights predicted by conjecture 1.1 but missing in the predictions of [ADP02]. Doud has moreover verified for some particular tame $\rho$ that $\rho$ arises in no regular weights outside $W^?(\rho|_{I_p})$ (at least in level $N^2(\rho)$).

Second, when $n = 4$ we produce many odd, tame $\rho$ and Serre weights $F$ such that $F \in W^2(\rho|_{I_p}) \cap W(\rho)$ (see 10.18 and 10.7 for a precise description of which pairs $(\rho|_{I_p}, F)$ are obtained). Our method is to obtain first Hecke eigenvectors in group cohomology with complex coefficients from cohomological automorphic representations of $GL_4/\mathbb{Q}$ whose associated $p$-adic Galois representation is known, and then to “reduce mod $p$.” We use representations automorphically induced from carefully chosen Hecke characters over non-Galois quartic CM fields. The main limitations of this method are that essentially only the Serre weights lying in the lowest alcove can be lifted to characteristic zero (as representations of the ambient algebraic group $GL_n/\mathbb{Q}$)—although weaker evidence for higher alcoves is obtained—and that the Serre weights have to satisfy a symmetry condition coming...
from a corresponding condition on the infinity type of cuspidal, algebraic automorphic representations of $GL_n/\mathbb{Q}$ [Clo90, p. 144]. The argument also goes through for $GL_{2m}$ with $m > 2$ whenever the required automorphic inductions are known to exist. We remark that for $n = 3$ a similar method was employed in [ADP02, §4] using symmetric square liftings of modular forms.

We also show that conjecture 1.1 is compatible with other conjectures. On the one hand we verify for generic tame $\rho|_{I_p}$ the compatibility with a conjecture of Gee predicting a certain closure property of $W^2(\rho|_{I_p})$ (see (9.1)). On the other hand we show that the predicted weight set in the Serre-type conjecture of Buzzard, Diamond, and Jarvis [BDJ] (in many cases a theorem of Gee) for two-dimensional, irreducible, totally odd, mod $p$ representations $\rho$ of the Galois group of a totally real field that is unramified at $p$ can be expressed completely analogously to conjecture 1.1 in the tamely ramified case (restricting to regular weights). This contrasts with the result of Diamond [Dia] that in this case, the conjectural weight set itself (at a prime dividing $p$) is essentially equal to the Jordan-Hölder constituents of the reduction “mod $p$” of an irreducible characteristic zero representation. The possibility of relating the set of Serre weights of $\rho$ to the reduction of characteristic zero representations in two ways (with or without $\mathcal{R}$) reflects the fact for $n = 2$ there is just one relevant alcove. For $n > 2$ an operator like $\mathcal{R}$ is “necessary,” as $\mathcal{R}$ interchanges alcoves with different numbers of predicted Serre weights.

Unfortunately we were unable to formulate a conjecture including the non-regular Serre weights of $\rho$, but we expect more complicated boundary phenomena based on considerations of local crystalline lifts. We were able to account for all weights predicted by the conjecture of Buzzard, Diamond, and Jarvis in the tame case by using a multi-valued extension of $\mathcal{R}$ (see thm. 11.3).

Finally let us remark that we formulated many parts of this paper for groups more general than $GL_n$ in the hope of its future usefulness. We will in fact apply some of the results in the case of $GSp_4$ in forthcoming work with Jacques Tilouine [HT].

The paper is structured as follows. In §§3–5 we review the relevant representation theory of $GL_n(\mathbb{F}_q)$ (and more general groups) and Jantzen’s results on the decomposition “mod $p$” of Deligne-Lusztig representations. In §6 we define $\mathcal{R}$, $V(\rho|_{I_p})$, state the conjecture in (6.9) and discuss its generic behaviour. §7 is devoted to a detailed comparison with the conjecture of Ash, Doud, Pollack, and Sinnott when $n = 3$. We list the computations of Doud and Pollack providing numerical evidence in §8. The following section contains the generic compatibility result with the conjecture of Gee. In §10 we obtain evidence for the conjecture from automorphic representations of $GL_4$, and in §11 we discuss the compatibility with the conjecture of Buzzard-Diamond-Jarvis.
1.1. **Acknowledgements.** This paper grew out of my Harvard thesis [Her06]. I am deeply indebted to my supervisor, Richard Taylor, for his invaluable guidance and unfailing support. I am very grateful to Jens Carsten Jantzen for generalising his result about the decomposition of Deligne-Lusztig representations and for answering other questions. The computations that Darrin Doud and David Pollack undertook for me were crucial, and I thank them very much for their willingness to assist me in this way. I am grateful to Avner Ash and to Fred Diamond for very helpful discussions and for their encouragement. I also want to thank Christophe Breuil, Kevin Buzzard, Gaétan Chenevier, Matt Emerton, Toby Gee, Michael Harris, Guy Henniart, Mark Reeder, Michael Schein, and Teruyoshi Yoshida for helpful comments and discussions. Finally I thank the I.H.É.S. for the excellent working conditions it provided during my stay in 2006/07 when some of this work was carried out.

2. Notation

Throughout, $p$ denotes a prime number and $q = p^r$. Fix an algebraic closure $\overline{\mathbb{Q}}_p$ of $\mathbb{Q}_p$ and denote by $\mathbb{F}_p$ its residue field. For all $n$, let $\mathbb{Q}_{p^n} \subset \overline{\mathbb{Q}}_p$ denote the unique subfield which is unramified and of degree $n$ over $\mathbb{Q}_p$ and let $\mathbb{F}_{p^n} \subset \mathbb{F}_p$ denote the unique subfield of cardinality $p^n$.

Fix an embedding $\overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_p$, and let $G_p$ (resp. $I_p$) denote the corresponding decomposition group (resp. inertia group) in $G_\mathbb{Q} = \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$. A (choice of) geometric Frobenius element at $l$ will be denoted by $\text{Frob}_l$. We will normalise the local Artin map so that geometric Frobenius elements correspond to uniformisers. Let $\tilde{\cdot} : \mathbb{F}_p^\times \to \overline{\mathbb{Q}}_p^\times$ denote the Teichmüller lift.

All Galois representations we consider are assumed to be *continuous*.
2.1. **Hecke pairs and Hecke algebras.** We will generally use the same terminology as Ash-Stevens [AS86], but prefer left actions for our modules. Thus a Hecke pair is a pair \((\Gamma, S)\) consisting of a subgroup \(\Gamma\) and a subsemigroup \(S\) of a fixed ambient group \(G\) such that

(i) \(\Gamma \subset S\).

(ii) \(\Gamma\) and \(s\Gamma s^{-1}\) are commensurable for all \(s \in S\).

The Hecke algebra \(H(\Gamma, S)\) consists of left \(\Gamma\)-invariant elements in the free abelian group of left cosets \(s\Gamma (s \in S)\), with the usual multiplication law:

\[ \sum a_i(s_i \Gamma) \sum b_j(t_j \Gamma) = \sum a_i b_j(s_i t_j \Gamma), \]

where \(a_i, b_j \in \mathbb{Z}, s_i, t_j \in S\). In particular, any double coset \(\Gamma s \Gamma = \biguplus_i s_i \Gamma\) (a finite disjoint union) becomes a Hecke operator in \(H(\Gamma, S)\) in the natural way; it is denoted by \([\Gamma s \Gamma]\). If \(M\) is a left \(S\)-module (over any ring), the group cohomology modules \(H^\bullet(\Gamma, M)\) inherit a natural linear action of \(H(\Gamma, S)\). This action is \(\delta\)-functorial, i.e., long exact sequences associated to short exact sequences of \(S\)-modules are \(H(\Gamma, S)\)-equivariant. It is thus determined by demanding that

\[ [\Gamma s \Gamma]m = \sum_i s_i m \]

for all \(s \in S, m \in H^0(\Gamma, M)\). It is also possible to explicitly describe the action on cocycles in any degree (see [AS86], p. 194).

A Hecke pair \((\Gamma_0, S_0)\) is compatible with \((\Gamma, S)\) if \(\Gamma_0 \subset \Gamma, S_0 \subset S, S_0 \Gamma = S,\) and \(\Gamma \cap S_0^{-1} S_0 = \Gamma_0\). In this case, it is easy to check that there is a natural injection

\[ H(\Gamma, S) \hookrightarrow H(\Gamma_0, S_0) \]

induced by restriction from the map on left cosets sending \(s_0 \Gamma \mapsto s_0 \Gamma_0\) \((s_0 \in S_0)\).

It will moreover be convenient to introduce a stronger relation. Let us say that two compatible Hecke algebras \((\Gamma_0, S_0), (\Gamma, S)\) are strongly compatible if \(\Gamma s_0 \Gamma = \Gamma_0 s_0 \Gamma\) for all \(s_0 \in S_0\) (equivalently, \(\Gamma = \Gamma_0 (\Gamma \cap s_0 \Gamma s_0^{-1})\) for all \(s_0 \in S_0\)). It is easy to see that this is precisely the condition to make the induced injection on Hecke algebras an isomorphism. Note that this isomorphism identifies \([\Gamma s \Gamma]\) with \([\Gamma_0 s_0 \Gamma_0]\) for all \(s_0 \in S_0\).

3. **Representations of \(GL_n(\mathbb{F}_q)\) in characteristic \(p\)**

In this section we will review some relevant results of the modular representation theory of groups like \(GL_n(\mathbb{F}_q)\). The main reference is [Jan03].

3.1. **Generalities.** Let \(G_0\) be a connected, split reductive group over \(\mathbb{F}_p\) and let \(G = G_0 \times_{\mathbb{F}_p} \overline{\mathbb{F}_p}\). We will consider \(G\) as defined over \(\mathbb{F}_q\). We start with a model over \(\overline{\mathbb{F}_p}\) in order to have at our disposal the \(p\)-power relative Frobenius morphism \(F_p : G \to G\) obtained as base change of the absolute Frobenius morphism of \(G_0\).
Let $T \subset G$ be a maximal torus defined and split over $\mathbb{F}_q$ with character group $X(T)$. Let $R \subset X(T)$ be the set of roots of $(G, T)$. For any $\alpha \in R$, $\alpha^\vee$ denotes the associated coroot. Choose a set of positive roots $R^+$ and let $\alpha_i$ denote the simple roots. By $B \supset T$ we denote the corresponding Borel subgroup and by $B^-$ the opposite Borel. Let $W = N(T)/T$ be the Weyl group of $(G, T)$ and $X(T)_+$ the monoid of dominant weights with respect to our choice of positive roots.

$W$ acts on $X(T)$ via $(w, \mu) \mapsto \mu \circ w^{-1}$. It will be useful in the following to also use a modified action. Choose $\rho' \in \frac{1}{2} \sum_{\alpha \in R^+} \alpha + (X(T) \otimes \mathbb{Q})^W$ and define the “dot action” of $W$ by

$$w \cdot \lambda := w(\lambda + \rho') - \rho'.$$

(3.1)

Of course, this is independent of the choice of $\rho'$. Note also that $\langle \rho', \alpha_i^\vee \rangle = 1$ for all $i$. (In the literature, usually $\rho' = \frac{1}{2} \sum_{\alpha \in R^+} \alpha$ is used and denoted by $\rho$. We prefer to reserve the letter “$\rho$” for a more convenient choice of $\rho'$ in the case of $G = GL_n$.)

Any $\lambda \in X(T)$ can be considered as character of $B^-$ via the natural map $B^- \rightarrow T$. For $\lambda \in X(T)_+$ the (dual) Weyl module $W(\lambda)$ is defined as algebraic induced module:

$$W(\lambda) = \text{ind}_{B^-}^G(\mathbb{F}_p(\lambda))$$

$$= \{ f \in \text{Mor}(G, \mathbb{G}_a) : f(bg) = \lambda(b)f(g) \forall g \in G, \ b \in B^- \}.$$

(For non-dominant $\lambda$, this induced module is zero.) This is a finite-dimensional $\mathbb{F}_p$-vector space, which becomes a left $G$-module in the natural way:

$$(xf)(g) = f(gx) \forall g, x \in G; \ f \in W(\lambda).$$

Let $F(\lambda) := \text{soc}_G W(\lambda)$ (the socle of the Weyl module, as $G$-module).

**Theorem 3.3.** The set of simple $G$-modules is $\{F(\lambda) : \lambda \in X(T)_+\}$. If $F(\lambda) \cong F(\mu)$ ($\lambda, \mu \in X(T)_+$) then $\lambda = \mu$.

More generally, considered in the Grothendieck group of $G$-modules we can extend the definition of Weyl module to all of $X(T)$ [Jan03 II.5.7]:

$$W(\lambda) = \sum_i (-1)^i(R^i \text{ind}_{B^-}^G(\mathbb{F}_p(\lambda))).$$

(If $\lambda$ is dominant, only the $i = 0$ term is non-zero, so this agrees with the previous definition.) The context should always make it clear whether $W(\lambda)$ refers to a genuine representation (and $\lambda$ dominant) or to an element of the Grothendieck group. The formal character is given by the Weyl character formula [Jan03 II.5.10]:

$$\text{ch } W(\lambda) = \sum_{w \in W} \det w \cdot e(w(\lambda + \rho')) \sum_{w \in W} \det w \cdot e(w(\rho')) \in \mathbb{Z}[X(T)]^W.$$

(3.4)

Here $e(\lambda) \in \mathbb{Z}[X(T)]$ denotes the weight $\lambda$ considered in the group algebra. In particular it follows that

$$W(w \cdot \lambda) = \det(w)W(\lambda),$$

(3.5)
and in turn that $W(\lambda) = 0$ if and only if $\lambda + \rho'$ lies on the wall of a Weyl chamber, whereas in all other cases, this formula allows to express $W(\lambda)$ as $\pm W(\lambda_\pm)$ with $\lambda_\pm$ dominant.

Note also that the map

$$\text{ch} : \{G\text{-modules}\} \to \mathbb{Z}[X(T)]^W$$

induces an isomorphism between the Grothendieck group of $G$-modules and $\mathbb{Z}[X(T)]^W$ [Jan03 II.5.8].

**Definition 3.6.**

$$X^0(T) = \{\lambda \in X(T) : \langle \lambda, \alpha^\vee \rangle = 0 \quad \forall \alpha \in R\}.$$ The set of $q$-restricted weights is defined to be:

$$X_r(T) = \{\lambda \in X(T) : 0 \leq \langle \lambda, \alpha^\vee \rangle < q = p^r \quad \text{for all simple roots } \alpha\}.$$ \vspace{0.5em}

**Remark 3.7.** Note that $X^0(T) = X(T)^W$, by looking at the basic reflections $s_\alpha$ ($\alpha \in R$) generating $W$. If $\nu \in X^0(T)$ then $W(\nu) = F(\nu)$ is a one-dimensional representation with character $e(\nu)$ by the Weyl character formula. From (3.2) we get for $\mu \in X(T)_+$,

$$W(\mu + \nu) \cong W(\mu) \otimes W(\nu), \quad F(\mu + \nu) \cong F(\mu) \otimes F(\nu).$$

**Proposition 3.8 (Brauer’s formula).** If $\sum_{\mu \in X(T)} a_\mu e(\mu) \in \mathbb{Z}[X(T)]^W$, then for all $\lambda \in X(T),$

$$\text{ch} W(\lambda) \cdot \sum_{\mu \in X(T)} a_\mu e(\mu) = \sum_{\mu \in X(T)} a_\mu \text{ch} W(\lambda + \mu).$$

For the simple proof, see for example [Jan77 §2(1)].

For any $i \geq 0$ and any $G$-module $V$, corresponding to a homomorphism $r : G \to GL(V)$, define a new $G$-module $V^{(i)}$ which equals $V$ abstractly but whose $G$-action is obtained by composing $r$ with $F_p^i.$

**Theorem 3.9 (Steinberg).** Suppose $\lambda = \sum_{i=0}^r \lambda_i p^i$ with $\lambda_i \in X_1(T).$ Then

$$F(\lambda) \cong F(\lambda_0) \otimes F(\lambda_1)^{(1)} \otimes \ldots \otimes F(\lambda_r)^{(r)}.$$

For a proof using the representation theory of Frobenius kernels see [Jan03 II.3.17].

Now we can state the classification theorem for irreducible modular representations of $G_0(F_q)$, under a further condition on $G$. This version is a slight extension of the one in [Jan87 app. 1], where in addition $G$ is assumed to be semisimple.

**Theorem 3.10 ([Jan05]).** Suppose that $G$ has simply connected derived group (e.g., $G = GL_n$).

(i) If $\lambda \in X_r(T)$, $F(\lambda)$ is irreducible as representation of $G_0(F_q)$. Any irreducible representation of $G_0(F_q)$ over $\overline{\mathbb{F}}_p$ arises in this way.

(ii) $F(\lambda) \cong F(\mu)$ as representation of $G_0(F_q)$ if and only if $\lambda - \mu \in (q - 1)X^0(T)$. 
3.2. Alcoves and the decomposition of Weyl modules. For any $\alpha \in R$ and any $n \in \mathbb{Z}$ consider the affine reflection on $X(T) \otimes \mathbb{R}$,

$$s_{\alpha, np}(\lambda) = \lambda - (\langle \lambda + \rho', \alpha^\vee \rangle - np)\alpha.$$ 

These generate the affine Weyl group $W_p := p\mathbb{Z}R \rtimes W$, defined with respect to the natural action of $W$ on $\mathbb{Z}R$, which we identify with its image in the group of affine linear automorphisms of $X(T) \otimes \mathbb{R}$ as follows:

$$(pw, w) \cdot \lambda := w \cdot \lambda + pw$$

(see the dot-action (3.1)). We will moreover set $\widetilde{W}_p := pX(T) \rtimes W$. For $\alpha \in R$ and any $n \in \mathbb{Z}$ denote by

$$H_{\alpha, np} = \{ \lambda : \langle \lambda + \rho', \alpha^\vee \rangle = np \}$$

the hyperplane fixed by $s_{\alpha, np}$.

**Definition 3.12.** An alcove is a connected component of the complement of these hyperplanes in $X(T) \otimes \mathbb{R}$.

In particular there is the “lowest alcove”

$$C_0 = \{ \lambda : 0 < \langle \lambda + \rho', \alpha^\vee \rangle < p \ \forall \alpha \in R^+ \}.$$ 

It can easily be checked that $W_p$ and even $\widetilde{W}_p$ map alcoves to alcoves; in fact, $\overline{C_0}$ is a fundamental domain for the $W_p$-action.

**Definition 3.13.** An alcove $C$ is restricted if it is contained in the restricted region

$$(3.14) \quad A_{res} = \{ \lambda : 0 < \langle \lambda + \rho', \alpha_i^\vee \rangle < p \ \forall i \}. $$

An alcove $C$ is dominant if it is contained in

$$\{ \lambda : 0 < \langle \lambda + \rho', \alpha_i^\vee \rangle \ \forall i \}. $$

Note that the restricted region $A_{res}$ is related to the set of $p$-restricted weights (3.6) as follows:

$$X(T) \cap A_{res} \subset X_1(T) \subset X(T) \cap \overline{A_{res}}. $$

Also, it is clear from the definition that $\overline{A_{res}}$ is a union of closures of alcoves.

**Definition 3.15.**

(i) Suppose that $\lambda, \mu \in X(T)$. We will say $\lambda \uparrow \mu$ if there exist $s_i := s_{\alpha_i, p n_i} \in W_p$ with $\alpha_i \in R, n_i \in \mathbb{Z}$ for $1 \leq i \leq r$ such that

$$\lambda \leq s_1 \cdot \lambda \leq s_2 s_1 \cdot \lambda \leq \cdots \leq s_r \cdots s_2 s_1 \cdot \lambda = \mu.$$ 

(ii) Suppose that $C_0 \cap X(T) \neq \emptyset$. Given alcoves $C, C'$, pick $\lambda \in C$ and let $\lambda'$ be the unique element of $W_p \cdot \lambda \cap C'$. Then

$$C \uparrow C' :\iff \lambda \uparrow \lambda'.$$
Note that
\[ \lambda \uparrow \mu \implies \lambda \leq \mu \text{ and } \lambda \in W_p \cdot \mu \]
but the converse does not hold in general. One verifies that the second part of the definition is independent of the choice of \( \lambda \). There is a natural definition even if \( C_0 \) contains no weights \([\text{Jan03}, \text{II.6.5}]\). In any case, \( C_0 \) is the lowest dominant alcove with respect to \( \uparrow \). If \( C \uparrow C' \) we will also say that \( C \) lies below alcove \( C' \) and \( C' \) above \( C \).

The following result, the so-called “strong linkage principle” of Jantzen and Andersen \([\text{Jan03}, \text{II.6.13}]\), is crucial in the representation theory of reductive groups in prime characteristic.

**Proposition 3.16.** Suppose that \( \lambda, \mu \in X(T)_+ \) and that \( F(\lambda) \) is a constituent of \( W(\mu) \). Then \( \lambda \uparrow \mu \).

### 3.3. The case of \( GL_n \).

To apply these results to \( GL_n \), let \( T \) be the diagonal matrices and \( B \) the upper-triangular matrices. Denote by \( \epsilon_i \in X(T) \) the character
\[ \begin{pmatrix} t_1 & t_2 & \cdots & t_n \end{pmatrix} \mapsto t_i, \]
and we identify \( X(T) \) with \( \mathbb{Z}^n \), also writing \( (a_1, a_2, \ldots, a_n) \) for \( \sum a_i \epsilon_i \). Then \( R = \{ \epsilon_i - \epsilon_j : i \neq j \} \) and the simple roots are given by \( \alpha_i = \epsilon_i - \epsilon_{i+1} \) for \( 1 \leq i \leq n - 1 \). The coroot \( (\epsilon_i - \epsilon_j) \vee \) for \( i \neq j \) then sends \( t \) to a diagonal matrix whose only entries are 1’s except for a \( t \) in the \((i, i)\)-entry and a \( t^{-1} \) in the \((j, j)\)-entry. We will identify \( W \) with \( S_n \) so that \( w(\epsilon_i) = \epsilon_{w(i)} \).

Then \( X^0(T) = (1, \ldots, 1) \mathbb{Z} \), \( X_r(T) = \{(a_1, \ldots, a_n) : 0 \leq a_i - a_{i+1} \leq q - 1 \forall i \} \), \( (a_1, \ldots, a_n) \) is dominant if and only if \( a_1 \geq \cdots \geq a_n \). We may choose \( \rho' = (n - 1, n - 2, \ldots, 1, 0) \).

**Corollary 3.17.**

(i) The irreducible \( GL_n \)-modules over \( \overline{\mathbb{F}}_p \) are the \( F(a_1, \ldots, a_n) \), \( a_1 \geq \cdots \geq a_n \).

(ii) The irreducible representations of \( GL_n(\mathbb{F}_q) \) over \( \overline{\mathbb{F}}_p \) are the \( F(a_1, \ldots, a_n) \), \( 0 \leq a_i - a_{i+1} \leq q - 1 \forall i \). \( F(a_1, \ldots, a_n) \cong F(a'_1, \ldots, a'_n) \) if and only if \( (a_1, \ldots, a_n) - (a'_1, \ldots, a'_n) \in (q - 1, \ldots, q - 1) \mathbb{Z} \).

(iii) Any irreducible representation of \( GL_n(\mathbb{F}_q) \) over \( \overline{\mathbb{F}}_p \) can be written as
\[ M_0 \otimes_{\overline{\mathbb{F}}_p} M_1^{(1)} \otimes_{\overline{\mathbb{F}}_p} \cdots \otimes_{\overline{\mathbb{F}}_p} M_{r-1}^{(r-1)} \]
for unique irreducible representations \( M_i = F(\lambda_i) \) with \( \lambda_i \in X_1(T) \).

The number of restricted alcoves is \( (n - 1)! \) (see p. 13).

Suppose that \( n = 2 \). The only restricted alcove is \( C_0 = \{(a, b) \in \mathbb{R}^2 : -1 < a - b < p - 1 \} \). If \((a, b) \in X_1(T)\), we claim that \( F(a, b) \cong \text{Sym}^{a-b} \overline{\mathbb{F}}_p^2 \otimes \det^b \).

First note that \( F(a, b) = W(a, b) \) by the strong linkage principle \([3.16]\).

For any homogeneous polynomial \( F \) of degree \( a - b \), \( (x_1 x_2 x_3) \mapsto (x_1 x_2 - \ldots \)
$x_2 x_3$ of $F(x_1, x_2)$ is in $W(a, b)$ and these elements form a subrepresentation isomorphic to $\text{Sym}^{a-b} \mathbb{R}^p \otimes \det^b$. By irreducibility the claim follows.

Suppose that $n = 3$. The two restricted alcoves are the “lower alcove”

$$C_0 = \{(a, b, c) \in \mathbb{R}^3 : -1 < a - b, b - c \text{ and } a - c < p - 2\}$$

and the “upper alcove”

$$C_1 := \{(a, b, c) \in \mathbb{R}^3 : p - 2 < a - c \text{ and } a - b, b - c < p - 1\}.$$

**Proposition 3.18** (Jantzen). Suppose that $(a, b, c) \in X_1(T)$.

(i) If $(a, b, c)$ is in the upper alcove then there is a (non-split) exact sequence

$$0 \to F(a, b, c) \to W(a, b, c) \to F(c + p - 2, b, a - p + 2) \to 0.$$

(ii) Otherwise, i.e., if $(a, b, c)$ is in the lower alcove or on the boundary of the upper alcove, $F(a, b, c) = W(a, b, c)$.

**Notation:** $\tau(a, b, c) = (c + p - 2, b, a - p + 2)$.

**Proof.** (ii) follows from the strong linkage principle (3.16). (i) is a consequence of prop. II.7.11 and lemma II.7.15 [Jan03]: let $\lambda = (a, b, c)$. Then $\tau \lambda = (c + p - 2, b, a - p + 2)$ is the unique weight which is strictly smaller than $\lambda$ in the $\uparrow$-ordering of $X(T)$. Pick a weight $\mu$ in the upper closure of the lower alcove, but not in the lower alcove itself (e.g. $\mu = (p - 2, 0, 0)$), and apply the translation functor $T^\mu_\lambda$ to the identity of formal characters

$$\text{ch } W(\lambda) = \text{ch } F(\lambda) + m \text{ch } F(\tau \lambda),$$

which holds for some integer $m$ by the strong linkage principle, to deduce that $m = 1$. \qed

Suppose that $n = 4$. Here is a list of all dominant alcoves below the top restricted one ($C_5$). They consist of all $(a, b, c, d) - p' \in X(T) \otimes \mathbb{R} = \mathbb{R}^4$ satisfying respectively:

$$
\begin{align*}
C_0 : & \quad 0 < a - b, b - c, c - d; a - d < p, \\
C_1 : & \quad 0 < b - c; p < a - d; a - c, b - d < p, \\
C_2 : & \quad 0 < c - d; p < a - c; a - b, b - d < p, \\
C_3 : & \quad 0 < a - b; p < b - d; c - d, a - c < p, \\
C_4 : & \quad p < a - c, b - d; b - c < p; a - d < 2p, \\
C_5 : & \quad 2p < a - d; a - b, b - c, c - d < p, \\
C_{0'} : & \quad 0 < b - c, c - d; p < a - b; a - d < 2p, \\
C_{0''} : & \quad 0 < a - b, b - c; p < c - d; a - d < 2p.
\end{align*}
$$

The first six alcoves in this list are the restricted ones. The $\uparrow$-ordering on the above eight alcoves of $GL_4$ is generated by $0 \uparrow 1 \uparrow i \uparrow 4 \uparrow 5$ ($i = 2, 3$), $2 \uparrow 0' \uparrow 5$, and $3 \uparrow 0'' \uparrow 5$.

The constituents of $W(\lambda)$ for $\lambda \in X_1(T)$ are known by [Jan74].
4. Representations of $GL_n(\mathbb{F}_q)$ in characteristic zero

The aim of this section is to recall relevant facts about the ordinary representations theory of $GL_n(\mathbb{F}_q)$. Since it will be convenient for reduction later, we will work over the field $\overline{\mathbb{F}}_p$.

4.1. Deligne-Lusztig representations. We allow $G$ to be slightly more general than in the previous section: $G = G_0 \times_{\mathbb{F}_q} \overline{\mathbb{F}}_p$ for a connected reductive group $G_0$ over $\mathbb{F}_q$. We will identify a variety over $\overline{\mathbb{F}}_p$ with the set of its $\overline{\mathbb{F}}_p$-rational points. Let $F$ denote the relative ($q$-power) Frobenius morphism, so $G^F = G_0(\mathbb{F}_q)$. We assume that the maximal torus $T$ is $F$-stable (not necessarily split over $\mathbb{F}_q$).

To each pair $(\mathbb{T}, \theta)$ consisting of an $F$-stable maximal torus $\mathbb{T}$ and a homomorphism $\theta: \mathbb{T}^F \to \mathbb{Q}_p^\times$, Deligne-Lusztig [DL76] associate a virtual representation $R^\theta_{\mathbb{T}}$ of $G^F$ (defined in terms of the étale cohomology of a variety over $\overline{\mathbb{F}}_p$ having commuting $\mathbb{T}^F$- and $G^F$-actions). We will recall the relevant facts, together with Jantzen’s parameterisation [Jan81, 3.1], [Jan05, A.7].

Given $w \in W$, by Lang’s theorem there is a $g_w \in G$ such that $g_w^{-1}F(g_w)$ is a lift of $w$ in $N(T)$. Then $T_w := g_w T$ is an $F$-stable maximal torus, well defined up to $G^F$-conjugacy. Two elements $w, w' \in W$ are said to be $F$-conjugate if $w = \sigma^{-1}w'F(\sigma)$ for some $\sigma \in W$ (note that the natural $F$-action on $W$ is trivial if $G$ is split over $\mathbb{F}_q$). The map sending $w \in W$ to $T_w$ induces a bijection between $F$-conjugacy classes in $W$ and $G^F$-conjugacy classes of $F$-stable maximal tori. We say that the type of $T_w$ is (the $F$-conjugacy class of) $w$.

If $\mu \in X(T)$ let

$$\theta_{w, \mu}: T_w^F \to \mathbb{Q}_p^\times, \quad t_w \mapsto \tilde{\mu}(g_w^{-1}t_w g_w).$$

(Recall that $\tilde{\mu}$ denotes the Teichmüller lift.) Form the semi-direct product $X(T) \rtimes W$ where $w \in W$ acts on $\mu \in X(T)$ as $F(w)(\mu)$. The group $X(T) \rtimes W$ acts on the set $W \times X(T)$ as follows:

$$(\nu, \sigma)(w, \mu) = (\sigma w F(\sigma)^{-1}, \sigma \mu + F(\nu) - \sigma w F(\sigma)^{-1} \nu).$$

In particular if $G$ is split over $\mathbb{F}_q$, $W$ acts on $X(T)$ in the natural way and the $X(T) \rtimes W$-action becomes

$$(\nu, \sigma)(w, \mu) = (\sigma w \sigma^{-1}, \sigma \mu + (q - \sigma w \sigma^{-1}) \nu).$$

We will also use the notation $(w, \mu) \sim (w', \mu')$ for elements of $W \times X(T)$ in the same $X(T) \rtimes W$-orbit.

Lemma 4.2.

$$\begin{align*}
\frac{W \times X(T)}{X(T) \rtimes W} \sim & \{ \text{pairs } (\mathbb{T}, \theta) \} / \sim \approx \\
& \{ \text{virtual representations } e_G \in_T R^\theta_{\mathbb{T}} \text{ of } G^F \text{ over } \mathbb{Q}_p \} / \approx
\end{align*}$$

$$(w, \mu) \mapsto (T_w, \theta_{w, \mu}); (\mathbb{T}, \theta) \mapsto e_G \in_T R^\theta_{\mathbb{T}}$$
where \( \epsilon_G = (-1)^{\text{ rank}(G)} \). If \((T_i, \theta_i)\) are not \( G^F \)-conjugate, then \( \langle P_{T_1}^{P_1}, P_{T_2}^{P_2} \rangle = 0 \).

Following Jantzen, we denote the image of \((w, \mu)\) under the composite of these maps by \( R_w(\mu) \). The choice of sign ensures that the character value at 1 is positive.

**Proof.** It is elementary to establish the bijection (the key point is \([\text{DM91}, 13.7(i)]\)). \([\text{DL76, 6.8}]\) implies that the second arrow is well defined and the claim about orthogonality which, in turn, entails the injectivity. \( \square \)

### 4.2. The case of \( GL_n \)

We let \( G = GL_n \) and keep the notations of \( \{3.3\} \).

For any decomposition \( n = \sum_{i=1}^r n_i \) with \( n_i > 0 \) there is a corresponding “parabolic” subgroup \( P_q(\mathbb{F}_q) \) in \( G^F = GL_n(\mathbb{F}_q) \) consisting of matrices with \( n_i \times n_i \) square blocks along the diagonal (in that order) with arbitrary entries above the blocks and zeroes below.

**Definition 4.3.** Suppose that \( n = \sum_{i=1}^r n_i \) and for each \( i, \sigma_i \) is a representation of \( GL_{n_i}(\mathbb{F}_q) \). We define the parabolic induction of the \( \sigma_i \) to be

\[
P\text{Ind}(\sigma_1, \ldots, \sigma_r) := \text{Ind}_{P_q(\mathbb{F}_q)}^{GL_n(\mathbb{F}_q)}(\sigma_1 \otimes \cdots \otimes \sigma_r).
\]

It is independent of the order of the \((n_i, \sigma_i)\). An irreducible representation \( \pi \) of \( GL_n(\mathbb{F}_q) \) (over \( \overline{\mathbb{F}_p} \)) is called **cuspidal** if \( \pi \) does not occur in any parabolic induction \( P\text{Ind}(\sigma_1, \ldots, \sigma_r) \) with \( r > 1 \). For any \( \pi \) there is a set \( \text{Supp}(\pi) = \{ \sigma_1, \ldots, \sigma_r \} \) uniquely determined by demanding that \( \pi \) occurs in \( P\text{Ind}(\sigma_1, \ldots, \sigma_r) \). (See e.g. \([\text{Bum97, ex. 4.1.17–20.}]\).

If \( l/k \) is an extension of finite fields and \( A \) an abelian group, we say that a homomorphism \( l^\times \to A \) is **\( k \)-primitive** if it does not factor through the norm map \( l^\times \to k_0^\times \) for any intermediate field \( k \subset k_0 \subset l \). More generally, for extensions \( l_i/k \) we say a homomorphism \( \prod l_i^\times \to A \) is **\( k \)-primitive** if each component \( l_i^\times \to A \) is.

**Lemma 4.4.** Suppose that \( w \in W \) is an \( n \)-cycle. Since \( T_w^F \cong T_w^F \) via \( g_w \), there is an identification \( T_w^F \cong \mathbb{F}_q^\times \), determined up to the action of the \( q \)-power map. Then

\[
\left\{ \begin{array}{c}
\mathbb{F}_q^\times \text{primitive} \\
\mathbb{F}_q^\times \theta \to \overline{\mathbb{F}_p}^\times
\end{array} \right\}/(\theta \sim \theta^q) \cong \left\{ \begin{array}{c}
\text{cuspidal representations} \\
\text{of } GL_n(\mathbb{F}_q) \text{ over } \overline{\mathbb{F}_p}
\end{array} \right\} / \cong (-1)^{n-1} R_{T_w}^\theta.
\]

**Proof.** Note that as \( w \) is an \( n \)-cycle, \( T_w \) has \( \mathbb{F}_q \)-rank one and hence is not contained in any proper \( F \)-stable parabolic subgroup. Also, no non-trivial element of \( (N(T_w)/T_w)^F \) (a cyclic group of order \( n \)) fixes \( \theta \) as \( \theta \) is \( \mathbb{F}_q \)-primitive. Then (5.15), (7.4) and (8.3) of \([\text{DL76}]\) show that \( R_w(\mu) \) is cuspidal.

The map is well defined and injective by lemma 4.2 noting that the \( G^F \) conjugacy class of the pair \((T_w, \theta)\) determines \( \theta \) up to \( (N(T_w)/T_w)^F \), i.e., up to \( q \)-power action.
For surjectivity we use \cite{Spr70a}. First note that a character is in the discrete series in Springer’s nomenclature \cite[§4.3]{Spr70a} if and only if it is cuspidal \cite[9.1.2]{Car85}. Theorems 8.6 and 7.12 in \cite{Spr70a} show that the cuspidal characters are precisely the ones denoted there by \( \chi_n(\phi) \), for \( F \)-primitive characters \( \phi : F^\times \to \overline{\mathbb{F}}_q^\times \) (and \( \mathbb{F}_q^\times \), naturally embedded in \( GL_n(\mathbb{F}_q) \); the image is denoted by \( T_n \) in Springer’s notes), with \( \chi_n(\phi) = \chi_n(\phi') \) if and only if \( \phi \) is in the \( q \)-power orbit of \( \phi' \). As the two constructions yield the same number of cuspidal representations and Springer shows that he constructs them all, we are done. (It is true that \( \chi_n(\phi) = (-1)^n-1 \mathbb{R}_{T_w}^\phi \) \cite[§2.1]{Her06}.)

**Definition 4.6.** Denote the cuspidal representation parameterised by \( \theta \) by \( \kappa(\theta) \). It follows from lemma 4.2 that it is independent of \( w \).

**Lemma 4.7.** Suppose that \( w \in W \cong S_n \). Write \( \{1, \ldots, n\} = \bigs Q \) disjoint union of orbits under the action of \( w \) and let \( n_i := \#S_i \). Via \( g_w \) there is an identification \( T_w^F \cong \prod F^\times_{n_i} \), well defined up to the action of the \( q \)-power map on each component. Suppose that \( \theta : T_w^F \to \overline{\mathbb{F}}_p^\times \) is \( F \)-primitive, and denote by \( \theta_i : F^\times_{n_i} \to \overline{\mathbb{F}}_p^\times \) its \( i \)-th component. Then

\[
R_{T_w}^\theta \cong \text{PInd}(\kappa(\theta_1), \ldots, \kappa(\theta_r)).
\]

**Proof.** First let \( P \) be the parabolic subgroup consisting of \( x \in GL_n \) with \( x_{\alpha, \beta} = 0 \) whenever \( \alpha \in S_i \), \( \beta \in S_j \) and \( i > j \). Similarly let \( L \) be the Levi subgroup of \( P \) defined by \( x_{\alpha, \beta} = 0 \) if \( i \neq j \). Then \( P_w = g_w P g_w^{-1} \) is an \( F \)-stable parabolic subgroup containing \( T_w \) (as \( P \) is \( wF \)-stable), and \( L_w = g_w L g_w^{-1} \) is an \( F \)-stable Levi subgroup. From \cite[8.2]{DL76},

\[
R_{T_w}^\theta \cong \text{Ind}_{P_w}^{G_w}(R_{T_w, P_w}^\theta) \quad \text{where the Deligne-Lusztig representation } R_{T_w, P_w}^\theta \text{ is computed inside } L_w \text{ and which becomes a representation of } P_w^F \text{ via } P_w^F \to L_w^F.
\]

But as \( n_w \in L \), without loss of generality \( g_w \in L \) (Lang’s theorem) in which case \( L = L_w \), \( P = P_w \) and \( P_w^F \) is \( GL_n(\mathbb{F}_q) \)-conjugate to \( P_n(\mathbb{F}_q) \) considered above. Finally \( L \) decomposes as \( \prod GL_n_i \) (as \( F_q \)-group) compatibly with the decomposition of \( w \) and \( \theta \). An application of Künneth’s theorem yields the result. \( \square \)

5. **Decomposition of \( GL_n(\mathbb{F}_q) \)-representations**

Suppose that \( V/\overline{\mathbb{F}}_p \) is a finite-dimensional representation of a finite group \( \Gamma \). Then we can define the (semisimplified) reduction of \( V \) “modulo \( p \)” to be \( \overline{V} := (M/m_{\overline{p}} M)^{ss} \) for any \( \Gamma \)-stable \( \mathbb{Z}_p \)-lattice \( M \subset V \). This is a semisimple representation over \( \mathbb{F}_p \) which, by the Brauer-Nesbitt theorem, is independent of the choice of \( M \).
5.1. **Jantzen’s formula.** In order to state Jantzen’s theorem on the decomposition of Deligne-Lusztig representations mod $p$ in the special case of $GL_n$, we will need to introduce some notations.

As $G' = SL_n$ is simply connected, for any simple root $\alpha$ there is a $\omega'_\alpha \in X(T)$ such that $\langle \omega'_\alpha, \beta^\vee \rangle = \delta_{\alpha\beta}$ for all simple roots $\alpha, \beta$. These are unique up to $X_0(T)$; in fact, $X(T) = X'(T) \oplus X^0(T)$ where $X'(T)$ is the sublattice spanned by the $\omega'_\alpha$. A possible choice is $\omega'_\alpha = \epsilon_1 + \cdots + \epsilon_i$ $(1 \leq i \leq n-1)$.

Note that $A_{res}$ is a fundamental domain for the translation action of $pX'_T$ on $X(T) \otimes \mathbb{R}$. Hence for any $\sigma \in W$ there is a unique $\rho'_\sigma \in X'_T$ such that $\sigma \cdot C_0 + p\rho'_\sigma$ is a restricted alcove. A simple argument shows that

$$\rho'_\sigma = \sum_{\alpha \text{ simple}} \omega'_\alpha$$

with $\sigma^{-1}(\alpha) < 0$.

[Jan77] [lemma 1]. Denoting the longest Weyl group element by $w_0$ we define, compatibly with (3.3),

$$\rho'_\sigma := \rho'_\sigma w_0 = \sum_{\alpha \text{ simple}} \omega'_\alpha \in \frac{1}{2} \sum_{\alpha \in R^+} \alpha + (X(T) \otimes \mathbb{Q})^W.$$

Let $\epsilon'_\sigma := \sigma^{-1} \rho'_\sigma$ and define

$$W_1 = \{ \sigma \in W : \sigma \cdot C_0 + p\rho'_\sigma = C_0 \}.$$

Via the dot action, $W$ acts on the set of alcoves modulo translations by elements of $pX'(T)$ (equivalently, on the set of restricted alcoves). The stabiliser of $C_0$ is $W_1$ by definition, and we see that the number of restricted alcoves is $(W : W_1)$ (with the notations of (3.3), so that there are $(n-1)!$ restricted alcoves. (For the root system of a simply connected group, $W_1$ is isomorphic to the root lattice modulo the weight lattice; see [Jan77], lemmas 3 and 2.)

It is known, due to a theorem of Hulsurkar, that the matrix

$$(\det(\tau) \text{ch} W(-\epsilon'_{\sigma w_0} + \epsilon'_\tau - \rho'))_{\sigma, \tau \in W}$$

with entries in $\mathbb{Z}[X(T)]^W$ is upper triangular with respect to some ordering of $W$ (not unique). It is easy to see that its diagonal entries are invertible, as the highest weight of the Weyl module is in $X^0(T)$ if $\sigma = \tau$. Denote by $\gamma'_{\sigma, \tau}$ the entries of the inverse matrix. These depend on the choice of the $\omega'_\alpha$ (in a simple way).

Not very much seems to be known about the matrix $(\gamma'_{\sigma, \tau})$; it is known to be diagonal if and only if $n \leq 3$.

**Theorem 5.2** ([Jan05] cor. 4.8). In the Grothendieck group of $GL_n(\mathbb{F}_q)$-modules,

$$R_w(\mu + \rho') = \sum_{\sigma, \tau \in W} \gamma'_{\sigma, \tau} W(\sigma \cdot (\mu - w\epsilon'_0) + q\rho'_\sigma).$$
Remark 5.3. The formula is easily seen to be independent of the choice of the $\omega'_{\alpha}$. On the other hand, the left-hand side depends only on the $X(T) \rtimes \tilde{W}$-orbit of $(w, \mu + \rho')$ which is not obvious on the right-hand side.

Remark 5.4. This theorem holds, in fact, for $G$ as in theorem 3.10 [Jan05]. Originally Jantzen proved the analogue of this theorem for simply-connected, quasi-simple groups defined and not necessarily split over a finite field [Jan81]. In fact, the above formula nearly follows from the one for $SL_n$: each ingredient in the formula restricts to its counterpart for $SL_n$. The only loss of generality is that for an irreducible representation $F$ of $GL_n(\mathbb{F}_q)$ appearing as Jordan-Hölder constituent of $R_w(\mu + \rho')$, $F|_{SL_n(\mathbb{F}_q)}$ determines $F$ only up to determinant-power twist. Taking into account the central character of $R_w(\mu + \rho')$, $F$ is determined up to a twist by $\det^r$ for integer multiples $r$ of $(q - 1)/n$. Thus if $\gcd(q - 1, n) = 1$, the formula follows from the one for $SL_n$. In general the formula for $GL_n$ is determined by demanding that it restricts to the one for $SL_n$ and that all highest weights occurring are polynomials in $q$ with coefficients in $\mathbb{Z}[X(T)]$.

Let us analyse the statement of Jantzen’s formula a little when $q = p$. Notice first that a typical highest weight appearing, $\sigma(\mu - w \varepsilon_{w w', \rho}) + pp'_\sigma - \rho'$, is a small deformation of $\sigma \cdot \mu + pp'_\sigma$. If $\mu$ lies in alcove $C$, the latter weight is contained in alcove $\sigma \cdot C + pp'_\sigma$. This alcove is automatically restricted if $C = C_0$, which can always be achieved, up to a small error, by varying $(w, \mu)$ (see (4.1)). We will continue to assume that $\mu$ lies in a small neighbourhood of $C_0$.

To use Jantzen’s formula to find the complete decomposition of $\tilde{R}_w(\mu)$ into irreducible $GL_n(\mathbb{F}_p)$-modules, we use Brauer’s formula (3.8) to express each $\gamma'_{\sigma, r}W(\lambda)$ as a linear combination of Weyl modules, thus

$$\tilde{R}_w(\mu) = \sum_{\nu} a_\nu W(\nu), \text{ some } a_\nu \in \mathbb{Z}.$$  

There is a small neighbourhood of the restricted region which contains all $\nu$ occurring in this expression. Any non-dominant $W(\nu)$ can be converted into a dominant one using (3.5). Next, one has to decompose each $W(\nu)$ as $GL_n$-module. This is a difficult problem which has not been solved in general (3.3), but in any case the possible highest weights of constituents are controlled by the strong linkage principle. In particular, these are close to the boundary of their alcove if the same is true for $\nu$.

Finally to decompose these as representations of $GL_n(\mathbb{F}_p)$, one uses the Steinberg tensor product theorem (3.9) and Brauer’s formula (3.8), noting that the Frobenius endomorphism is trivial on $GL_n(\mathbb{F}_p)$.

5.2. The generic case ($q = p$). In generic situations Jantzen found a way to describe the Jordan-Hölder constituents of $R_w(\mu + \rho')$ (including multiplicities) in terms of the constituents of a certain induced module of
\[ G_r T \subseteq G \ (G_r \text{ being the kernel of the Frobenius morphism } F). \] When \( r = 1 \), that is when \( q = p \),—and if we disregard multiplicities which will not concern us anyway—this can be made completely explicit due to a result of Ye.

Note first that alcoves for varying \( p \) can naturally be identified with each other: using the isomorphism \( X(T) \otimes \mathbb{R} \rightarrow X(T) \otimes \mathbb{R}, \mu - \rho' \mapsto \mu/p - \rho' \), alcoves are described independently of \( p \). For example, we can identify the lowest alcove \( C_0 \) for each \( p \).

We will say that \( \mu \in X(T) \) lies \( \delta \)-deep in an alcove \( C \) if
\[
(5.5) \quad n_\alpha p + \delta < \langle \mu + \rho', \alpha^\vee \rangle < (n_\alpha + 1)p - \delta \quad \forall \alpha \in R^+
\]
where \( C \) is the alcove determined by putting \( \delta = 0 \) in these inequalities \((n_\alpha \in \mathbb{Z})\). A statement in which \( p \) is allowed to vary is said to be true for \( \mu \) sufficiently deep in some alcove \( C \) if there is a \( \delta > 0 \), independent of \( p \), such that the statement is true for all \( \delta \)-deep \( \mu \in C \).

**Proposition 5.6.** Suppose that \( C \) is an alcove and that \( \mu \in X(T) \) lies sufficiently deep inside \( C \). Then the Jordan-Hölder constituents of \( R_w(\mu + \rho') \) are the \( F(\lambda) \) with \( \lambda \) restricted such that there exist \( \sigma \in W, \nu \in X(T) \) with \( \sigma \cdot (\mu + (w - p)\nu) \) dominant and
\[
(5.7) \quad \sigma \cdot (\mu + (w - p)\nu) \uparrow w_0 \cdot (\lambda - pp').
\]

**Remark 5.8.** Note that \( \lambda \mapsto w_0 \cdot (\lambda - pp') \) induces a bijection on \( A_{\text{res}}(3.14) \).

**Proof.** Note that possible values of the left-hand side of \( (5.7) \) are precisely the weight coordinates in the \( X(T) \times W \)-orbit of \((w, \mu + \rho')\) shifted by \(-\rho'\). Thus, without loss of generality, \( C = C_0 \). Let
\[
D_1 = \{ u \in \widetilde{W}_p : u \cdot \mu \in X_1(T) \}.
\]
The generalisation of Jantzen’s result [Jan81, 4.3] to \( GL_n \) is the following identity in the Grothendieck group of \( GL_n(\mathbb{F}_p) \)-representations, valid for \( \mu \) sufficiently deep in \( C_0 \):
\[
(5.9) \quad R_w(\mu + \rho') = \sum_{\substack{u \in D_1 \\ \nu \in X(T)}} [\tilde{Z}_1(\mu - p\nu + pp') : \tilde{L}_1(u \cdot \mu)] F(u \cdot (\mu + w\nu)).
\]
(The proof generalises without difficulty. See [Jan05, 2.1(3)] for the generalisation of [Jan81, 4.1(1)]. Note also that for \( GL_n \) no weight in an alcove is fixed by a non-trivial element of \( \widetilde{W}_p \) under the dot action.) Here \( \tilde{Z}_1(\lambda) \) and \( \tilde{L}_1(\lambda) \) for \( \lambda \in X(T) \) denote \( G_1T \)-modules as in [Jan03, §II.9], the latter being simple.

In order to apply the result of Ye, we will work with \( SL_n \) in this paragraph. Choose \( \sigma \in W \) such that \( \sigma(\mu - p\nu + \rho') \) is dominant. Then by [Jan03, II.9.16],
\[
(5.10) \quad [\tilde{Z}_1(\mu - p\nu + pp') : \tilde{L}_1(u \cdot \mu)] = [\tilde{Z}_1(\sigma \cdot (\mu - p\nu) + pp') : \tilde{L}_1(u \cdot \mu)].
\]
This integer is non-zero if and only if
\[ \sigma \cdot (\mu - p\nu) \uparrow w_0 u \cdot \mu + p(\sum_{\alpha} \alpha - \rho') \]
\[ = w_0 \cdot (u \cdot \mu - pp'). \quad (5.11) \]
(The “if” implication is due to Ye, as \( u \cdot \mu \) does not lie on an alcove wall, the “only if” implication is much easier and is even true for \( GL_n \). See [Jan03, II.9.7].) As the left-hand side is in \( X(T)_+ - \rho' \) and the right-hand side is in the closure of the restricted region, there are only finitely many choices of \( \nu \) for which this relation can be true (for any allowed \( \sigma \in W \) and any \( p \)). Thus by making \( \mu \) lie still further inside \( C_0 \) we may assume that \( \mu + w\nu \in C_0 \) for all such \( \nu \). As mentioned just after (5.15), we may replace both sides by weights in the same alcoves as long as they remain in the same \( W_p \)-orbit. We claim thus that
\[ \sigma \cdot ((\mu + w\nu) - p\nu) \uparrow w_0 \cdot (u \cdot (\mu + w\nu) - pp'). \quad (5.12) \]
This is easily verified since we can without loss of generality assume that \( p > n \) in which case \( W_p \) fixes no weight in an alcove (for \( SL_n \)).

Comparing with (5.10), this completes the proof except that we have to verify the equivalence between the multiplicity (5.10) being non-zero and (5.12) also holds for \( GL_n \). One observes first that \( \tilde{Z}_1(\lambda) \) and \( \tilde{L}_1(\lambda) \) restrict to the corresponding objects for \( SL_n \); this uses that \( G_1 T \cong U_1^- \times T \times U_1 \) as schemes [Jan03, II.9.7] and that these modules have a central character. The “only if” implication already holds by the above argument. For the “if” implication note that
\[ [\tilde{Z}_1(\lambda') : \tilde{L}_1(\mu')]_{GL_n} = [\tilde{Z}_1(\lambda') : \tilde{L}_1(\mu')]_{SL_n} \]
for \( \mu' \in W_p \cdot \lambda' \) with \( \lambda' \) (and hence \( \mu' \)) not lying on any alcove wall. This is because by [Jan81, II.9.15], any constituent of \( \tilde{Z}_1(\lambda) \) is of the form \( \tilde{L}_1(\nu') \) for some \( \nu' \in W_p \cdot \lambda' \) (even \( \nu' \uparrow \lambda' \)), the stabiliser of \( \lambda' \) in the affine Weyl group is trivial and since the natural projection \( X(T) \rightarrow X(T \cap SL_n) \) maps alcoves for \( GL_n \) to the ones for \( SL_n \) compatibly with the action of the affine Weyl group. It is thus enough to see that (5.12), equivalently (5.11), entails
\[ u \cdot \mu \in W_p \cdot (\sigma \cdot (\mu - p\nu) + pp'). \]
But this is immediate as \((\tau - 1)X(T) \subset ZR\) for \( \tau \in W \). \( \square \)

6. A Serre-type conjecture

From now on we will assume that \( n > 1 \).

6.1. Serre weights. The representation-theoretic analogue of the weight in Serre’s Conjecture is the following [AS00, BDJ].

Definition 6.1. A Serre weight is an isomorphism class of irreducible representations of \( GL_n(\mathbb{F}_p) \) over \( \mathbb{F}_p \). By (3.17), a Serre weight is of the form \( F(a_1, a_2, \ldots, a_n) \) with \( 0 \leq a_i - a_{i+1} \leq p - 1 \) for all \( i \). It is called regular if \( 0 \leq a_i - a_{i+1} < p - 1 \) for all \( i \).
Note that the number of Serre weights is $p^{n-1}(p - 1)$, which equals the number of semisimple conjugacy classes in $GL_n(F_p)$.

6.2. Hecke algebras. Fix a positive integer $N$ with $(N, p) = 1$. Let $\Gamma_1(N)$ be the group of matrices in $SL_n(\mathbb{Z})$ with last row congruent to $(0, \ldots, 0, 1)$ modulo $N$. Also let $S_1(N)$ be the group of matrices in $GL_n^+(\mathbb{Z}(N))$ with last row congruent to $(0, \ldots, 0, 1)$ modulo $N$ and let $S_1'(N) = S_1(N) \cap GL_n^+(\mathbb{Z}(NP))$. Here $\mathbb{Z}(N)$ is the ring of rational numbers with denominators prime to $N$.

Then $(\Gamma_1(N), S_1'(N)), (\Gamma_1(N), S_1(N))$ are Hecke pairs (see §2.1). The corresponding Hecke algebras over the integers are denoted by $\mathcal{H}_1'(N), \mathcal{H}_1(N)$; clearly $\mathcal{H}_1'(N) \subset \mathcal{H}_1(N)$ is a subalgebra.

For any prime number $l \nmid N$ choose $\omega_N(l) \in SL_n(\mathbb{Z})$ with last row congruent to $(0, \ldots, 0, l^{-1}) \pmod{N}$; then $\omega_N(l)\Gamma_1(N) = \Gamma_1(N)\omega_N(l)$ does not depend on any choices. For primes $l \mid N$ and $0 \leq i \leq n$ define the Hecke operator

$$T_{l,i} := [\Gamma_1(N)\left(\begin{smallmatrix} l & \cdots & 1 \\ \cdots & \cdots & \cdots \\ 1 & \cdots & 1 \end{smallmatrix}\right)\omega_N(l)\Gamma_1(N)],$$

in $\mathcal{H}_1(N)$ ($i$ diagonal entries being equal to $l$, $n - i$ equal 1). Here $\omega_N(l)$ stands for $\omega_N(l)$ if the diagonal matrix has an $l$ as its $(n, n)$-entry and for 1 otherwise. $T_{l,i}$ does not depend on the order of the diagonal entries. This follows from the proof of the following lemma:

Lemma 6.2.

$$\mathcal{H}_1(N) = \mathbb{Z}[T_{l,1}, T_{l,2}, \ldots, T_{l,n}, T_{l,n}^{-1} : l \nmid N]$$

$$\cup$$

$$\mathcal{H}_1'(N) = \mathbb{Z}[T_{l,1}, T_{l,2}, \ldots, T_{l,n}, T_{l,n}^{-1} : l \mid NP]$$

Proof sketch: Let $\Sigma_1(N) = M_n(\mathbb{Z}) \cap S_1(N)$ and $S_N = M_n(\mathbb{Z}) \cap GL_n^+(\mathbb{Z}(N))$. One checks that $(\Gamma_1(N), \Sigma_1(N)) \subset (SL_n(\mathbb{Z}), S_N)$ are strongly compatible Hecke pairs (§2.1), such that $T_{l,i}$ corresponds to $[SL_n(\mathbb{Z})\left(\begin{smallmatrix} l & \cdots & 1 \\ \cdots & \cdots & \cdots \\ 1 & \cdots & 1 \end{smallmatrix}\right)SL_n(\mathbb{Z})]$ ($i$ entries equal $l$). Finally one uses that $\mathcal{H}(SL_n(\mathbb{Z}), S_1)$ is a polynomial ring in the $T_{l,i}$ for all primes $l$ and all $1 \leq i \leq n$ [Shi77, §3.2], and one makes use of the grading on the Hecke algebras considered here induced by the determinant.

Whenever $M$ is an $\overline{F}_p[S_1'(N)]$-module and for any $e$, $\mathcal{H}_1'(N)$ acts on the group cohomology module $H^e(\Gamma_1(N), M)$. We will only consider the situation when $M = \overline{F}$, a Serre weight, with $S_1'(N)$ acting via the reduction mod $p$ map $S_1'(N) \to GL_n(\overline{F}_p)$.

Definition 6.3 ([AS00]). Suppose that $\alpha \in H^e(\Gamma_1(N), M)$ is an $\mathcal{H}_1'(N)$-eigenvector, say $T_{l,i}\alpha = a(l,i)\alpha$ for all $l \nmid pN$, $1 \leq i \leq N$. We say that a Galois representation $\rho : G_{\overline{Q}} \to GL_n(\overline{F}_p)$ is attached to $\alpha$ if for all $l \nmid pN,$
\(\rho\) is unramified at \(l\) and

\[(6.4) \quad \sum_{i=0}^{n} (-1)^{i}i^{(i-1)/2}a(l,i)X^i = \det(1 - \rho(Frob_l^{-1})X),\]

(Remember that \(\text{Frob}_l \in G_Q\) is a geometric Frobenius element at \(l\).)

**Remark 6.5.** A conjecture of Ash implies that for any Serre weight \(F\) and any \(H_1(N)\)-eigenvector in \(H^e(\Gamma_1(N), F)\) (any \((N,p) = 1, e \geq 0\) and \(n > 1\) there is an attached (semisimple) Galois representation \([\text{Ash92}],\) conjecture B). To see this, we will use the notations of \([7]\) and let \(\tilde{\Sigma}_1'(N) := \tilde{\Sigma}_1'(N) \cap M_n(\mathbb{Z})\). An \(H_1(N)\)-eigenvector gives rise to an \(H_1(N)\)-eigenpair \((\text{prop. 7.1})\) and \((\tilde{\Gamma}_1(N), \tilde{\Sigma}_1'(N))\) is a “congruence Hecke pair of level \(Np\)” \([\text{Ash92}],\) def. 1.2) as \(n > 1\).

Analogous to Serre’s Conjecture, we would like to understand, conversely, when a given \(n\)-dimensional Galois representation occurs in such a group cohomology module and, if so, for which prime-to-\(p\) levels \(N\) and Serre weights \(F\). Fix thus a Galois representation \(\rho : G_Q \to GL_n(\overline{\mathbb{F}}_p)\) which we assume to be irreducible and odd, in the following sense.

**Definition 6.6** \([\text{AS00}])\). We will say that \(\rho\) is odd if either \(p = 2\) or \(|n_+ - n_-| \leq 1\) where \(n_+\) (resp. \(n_-\)) is the number of eigenvalues of \(\rho(c)\) equal to 1 (resp. -1) where \(c \in G_Q\) is a complex conjugation.

Associated to \(\rho\) there is a prime-to-\(p\) integer \(N^2(\rho)\), its Artin conductor (see, for example, \([\text{ADP02}]\)). In Serre’s Conjecture this is the smallest prime-to-\(p\) level in which \(\rho\) appears.

**Definition 6.7.** Let \(W(\rho)\) (resp., \(W_{\text{opt}}(\rho)\)) be the set of regular Serre weights \(F\) such that \(\rho\) is attached to an \(H_1(N)\)-eigenvector in \(H^e(\Gamma_1(N), F)\) for some \(e \geq 0\) and some integer \(N\) prime to \(p\) (resp., \(N = N^2(\rho)\)).

**Remark 6.8.** As discussed in \([\text{ADP02}],\) rk. 3.2, when \(n = 3, e\) can be taken to be 3, the virtual cohomological dimension of \(\Gamma_1(N)\), in the definition.

Let us now state a Serre-type conjecture for \(n\)-dimensional Galois representations \(\rho\) that are tame at \(p\). It depends on two ingredients to be defined in the next two subsections: a representation \(V(\rho|_{I_p})\) of \(GL_n(\mathbb{F}_p)\) over \(\overline{\mathbb{Q}}_p\) and an operator \(\mathcal{R}\) on the set of Serre weights.

**Conjecture 6.9.** Suppose that \(\rho : G_Q \to GL_n(\overline{\mathbb{F}}_p)\) is irreducible, odd, and tamely ramified at \(p\). Then

\[W(\rho) = W_{\text{opt}}(\rho) = W^2(\rho|_{I_p}),\]

where \(W^2(\rho|_{I_p}) := \mathcal{R}(JH(V(\rho|_{I_p})))\).

By \(V(\rho|_{I_p})\) we mean, as in \([5]\) the reduction “modulo \(p\)” of a \(GL_n(\mathbb{F}_p)\)-stable \(\mathbb{Z}_p\)-lattice in \(V(\rho|_{I_p})\) and by \(JH(-)\) the set of Jordan-Hölder constituents (forgetting multiplicities).
Recall that the tame inertia group $I_p$ is isomorphic to $\lim \mathbb{F}_p$. This isomorphism is canonical with our conventions as we defined $\mathbb{F}_p$ to be the residue field of $\mathbb{Q}_p$ and $\mathbb{F}_p' \subset \mathbb{F}_p$ as the unique subfield of cardinality $p^i$. Recall also the fundamental characters $\omega_{p^i} : I_p \rightarrow \mathbb{F}_p$ for each $i$ obtained by projection from the above isomorphism (again canonical here). In particular, $\omega := \omega_1$ is the mod $p$ cyclotomic character.

The following basic proposition will be used later. The corresponding result for $W(\rho)$ follows in the same way as in [AS00], lemma 2.5 and prop. 2.8.

**Proposition 6.10.** Suppose that the tame inertial Galois representation $\tau : I_p \rightarrow GL_n(\mathbb{F}_p)$ extends to $G_p$. Then

(i) $W^? (\tau \otimes \omega) = W^? (\tau) \otimes \det$.

(ii) $W^? (\tau^\vee) = \{ F^\vee \otimes \det^{1-n} : F \in W^? (\tau) \}$.

**Proof.** For (i) this follows from the facts that $R \theta \cdot f \sim R \theta T \otimes \tilde{\det}$ [DL76, cor. 1.27] and that $R(F \otimes \det) \sim R(F) \otimes \det$.

For (ii) this follows from the facts that $R^{\theta-1} \otimes (R^\theta)^\vee$ [DL76, p. 136] and that $R(F^\vee) \simeq R(F) \otimes \det^{1-n}$. □

6.3. **The operator $R$ on Serre weights.** Consider the bijection

$$\{ \text{regular Serre weights} \} \rightarrow (\mathbb{Z}/(p-1))^n$$

$$F(a_1, \ldots, a_n) \mapsto (\overline{a_1}, \ldots, \overline{a_n}).$$

For any $b_i \in \mathbb{Z}$ define then $F(b_1, \ldots, b_n)_{reg}$ to be the regular Serre weight corresponding in this bijection to $(\overline{b_1}, \ldots, \overline{b_n})$.

We can then define the operator $R$ by

$$\{ \text{Serre weights} \} \rightarrow \{ \text{regular Serre weights} \}$$

$$F(a_1, \ldots, a_n) \mapsto F(a_n - (n-1), \ldots, a_2 - 1, a_1)_{reg}.$$ 

Thus on regular Serre weights, $R$ is an involution up to twist: $R^2(F) = F \otimes \det^{1-n}$. A more conceptual description is the following.

**Definition 6.11.** We let

$$\rho := (n-1, n-2, \ldots, 1, 0) \in \frac{1}{2} \sum_{\alpha \in R^+} \alpha + (X(T) \otimes \mathbb{Q})^W.$$

It thus also satisfies the condition imposed on $\rho'$ in §3.

**Remark 6.12.** Note that $R(F(\mu)) \simeq F(w_0 \cdot (\mu - p\rho))_{reg}$ for any $\mu \in X_1(T)$.

6.4. **The characteristic zero representation $V(\rho|_{I_p})$.** To make this as conceptual as possible, we will define it in the more general context of connected reductive groups defined and split over $\mathbb{F}_q$ (with connected centre) and then make it explicit for $GL_n$. We will use the notion of dual groups over a finite field, as formulated by Deligne-Lusztig [DL76]. The notations will be as in §3.
At first $G$ need not be split and there is no assumption on the centre. Our conventions for the actions of $F$ and $w \in W$ on $\mu \in X(T)$ and $\lambda \in Y(T)$ are as follows: $F(\mu) = \mu \circ F$, $F(\lambda) = F \circ \lambda$, $w(\mu) = \mu \circ w^{-1}$, $w(\lambda) = w \circ \lambda$.

**Definition 6.13.** Suppose $G^*$ is a connected reductive group defined over $\mathbb{F}_q$ with relative Frobenius morphism $F^*$ and $F^*$-stable maximal torus $T^*$. A duality between $(G, T)$ and $(G^*, T^*)$ is an isomorphism $\phi : X(T) \rightarrow Y(T^*)$ such that $F^*\phi = \phi F$ and such that both $\phi$ and $\phi^\vee : X(T^*) \rightarrow Y(T)$ send roots bijectively to coroots.

$G^*$ is called the dual group of $G$; it always exists and is unique up to isomorphism.

We get natural identifications of the Weyl groups so that $w\phi = \phi w$, but the Frobenius actions on $W$ are mutual inverses: $F^*(w) = F^{-1}(w)$. There is a natural bijection between rational conjugacy classes of Frobenius-stable maximal tori $T \subset G$ and $T^* \subset G^*$ so that a type $w$ torus in $G$ corresponds to a type $w^{-1}$ torus in $G^*$. Moreover it extends to a bijection between rational conjugacy classes of pairs $(\mathbb{T}, \theta)$ and pairs $(\mathbb{T}^*, s)$ where $\theta : T \rightarrow T^*$ and $s \in T^*F^*$. This depends on the choice of a generator $(\zeta_{p^i-1})_{i=1}^\infty \in \lim \mathbb{F}_p^X$: without loss of generality, $\mathbb{T} = T_w$. Then $\theta(q^w - )$ is a character of $T_{wF}$; extend it arbitrarily to a character $\mu \in X(T)$. Let $\bar{\mu} = \phi(\mu) \in Y(T^*)$ and choose a positive integer $t$ such that $T_{F^*(w^{-1})}^*$ (equivalently, $T_w$) is split over $\mathbb{F}_q^t$. Then the dual pair is

$$((T_{F^*(w^{-1})}^*, T_{F^*(w^{-1})}), (\theta, T_w))$$

[DM91] 13.13. Here we use the notation $N_{A^t/A} = \prod_{i=0}^{t-1} A^i$ for any $A \in \text{End}(Y(T^*))$.

An $F$-stable maximal torus $T \subset G$ is said to be maximally split if $T \subset B$ for some $F$-stable Borel subgroup $B$. Equivalently, $\mathbb{F}_q\text{-rank}(\mathbb{T}) = \mathbb{F}_q\text{-rank}(G)$ [Car85, 6.5.7]. All maximally split tori in $G$ are $G^F$-conjugate [Car85, 1.18].

**Definition 6.14** ([DL76, 5.25]). A pair $(\mathbb{T}, \theta)$ and its dual pair $(\mathbb{T}^*, s)$ (as above) are called maximally split if $\mathbb{T}^* \subset Z_{G^*}(s)^{\circ}$ is maximally split.

Note that if $s \in G^*$ is semisimple, then $Z_{G^*}(s)^{\circ}$ is connected reductive, and if $Z(G)$ is connected then $Z_{G^*}(s)^{\circ} = Z_{G^*}(s)$ (see (2.3) and (13.15) in [DM91]).

**Proposition 6.15.** Assume that $Z(G)$ is connected, and that $T$ (hence also $T^*$) is split over $\mathbb{F}_q$ Then we have the following commutative diagram:

$$
\begin{array}{ccc}
\left\{ \text{maximally split} \right\}/G^*F^* & \xleftarrow{\text{duality}} & \left\{ \text{maximally split} \right\}/G^F \\
\downarrow & & \downarrow \text{12} \\
\left\{ \text{tame } \tau : I_p \rightarrow G^*(*F_p) \right\}/ \cong \{ \text{virtual representations} \} / \cong \\
\end{array}
$$

...
Here \( G_q := \text{Gal}(\overline{\mathbb{Q}}_p / \mathbb{Q}_p) \) with inertia subgroup \( I_p \).

If \( (T_w, \theta_{w, \mu}) \) is maximally split for some \((w, \mu) \in W \times X(T)\), then under the above bijections it corresponds to the inertial Galois representation

\[
(6.16) \quad \tau(w, \mu) := N_{\langle F^*w^{-1}\rangle / F^*w^{-1}}(\bar{\omega}_\tau) .
\]

Here \( \bar{\mu} = \phi(\mu) \in Y(T^*) \) and \( t \) is any positive integer such that \( T^*_{F^*w^{-1}} \) is split over \( \mathbb{F}_q^t \) (equivalently, \( w^t = 1 \) as \( T^* \) is split).

In particular, \( V_\phi(\tau(w, \mu)) = R_w(\mu) \) and \( V_\phi \) is independent of the choice of \( (\zeta_{p^t - 1})_i \).

**Remark 6.17.** It is known that \( V_\phi(\tau) \) is a genuine representation in every case \([DL76] 10.10\).}

**Proof.** The bijection on the left is obtained as follows. The choice of \( (\zeta_{p^t - 1})_i \) induces a generator \( g_{\text{can}} \) of the maximal tame quotient \( I_p^t \xrightarrow{\sim} \lim \mathbb{F}_q \) of \( I_p \).

The isomorphism class of \( \tau \) is determined by the conjugacy class of \( \tau(g_{\text{can}}) \), i.e., a conjugacy class in \( G^* \) that is stable under \( x \mapsto x^t \) (as \( \tau \) extends to \( G_q^* \)) and whose members have prime-to-\( p \) order. An element \( g \in G^* \) has order prime to \( p \) iff it is semisimple (embed \( G^* \) in some \( GL_m \)). By conjugating \( g \) to \( T^* \) and using that \( T^* \) is split over \( \mathbb{F}_q \) we see that its conjugacy class contains \( g^t \) iff it contains \( F^*(g) \). A simple argument shows that \( F^* \)-stable semisimple conjugacy classes in \( G^* \) are in natural bijection with \( G^*F^* \)-conjugacy classes of semisimple elements in \( G^*F^* \) (see the proof of \([Car85] 3.7.3\); this uses that \( Z(G) \) is connected). Finally one shows that \( (T^*, s) \mapsto s \) induces a bijection from maximally split pairs to semisimple elements in \( G^*F^* \) (both up to \( G^*F^* \)-conjugacy). This only uses existence and uniqueness up to rational conjugacy of maximally split tori in \( Z_G(s)^0 \).

The explicit description of \( \tau \) associated to \((T_w, \theta_{w, \mu}) \) follows immediately from the description of the dual pair above. \( \square \)

**From now on suppose again that \( G = GL_n \) and \( T \) is the torus of diagonal matrices.** Let \((G^*, T^*) = (G, T)\) and let

\[
(6.18) \quad \phi : X(T) \xrightarrow{\sim} Y(T^*) \quad \quad (a_1, \ldots, a_n) \mapsto (a_1, \ldots, a_n)
\]

(the notation should be self-evident). This is clearly a duality in the sense defined above. Since a connected reductive group defined over \( \mathbb{F}_q \) is determined by its root datum together with the \( F \)-action on it \([DM91] 3.17\), \((G^*, T^*)\) is well defined up to isomorphism and any other duality between \((G, T)\) and \((G^*, T^*)\) differs by an automorphism of \((X(T), R, X(T)^\vee, R^\vee)\) commuting with \( F \) (the latter condition is automatic as \( T \) is split here). It is known and easy to verify that any such automorphism is, up to the Weyl group action, which leaves \( V_\phi \) unchanged, either trivial or given by \( (a_1, \ldots, a_n) \mapsto (-a_1, \ldots, -a_n) \) on \( X(T) \).
Thus there are two ways to define $V(\tau)$ which differ by $\tau \mapsto \tau^\vee$. These two choices corresponds to the two choices of normalising the Galois representation associated to a Hecke eigenvector (in (6.4), geometric Frobenius elements could be replaced by arithmetic ones). The above choice of $\phi$ is the one that will work here.

**Definition 6.19.** For a tame inertial Galois representation $\tau : I_p \to GL_n(\overline{\mathbb{F}}_p)$ that extends to $G_q$, we set $V(\tau) := V_\phi(\tau)$ with $\phi$ as in (6.18).

We will finally describe explicitly the maximally split pairs $(\mathbb{T}, \theta)$, which enables us to characterise the image of $V$.

**Definition 6.20.** Suppose that $(w, \mu) \in W \times X(T)$ with $\mu = (\mu_1, \ldots, \mu_n)$. For each $1 \leq i \leq n$, let $n_i$ denote the smallest positive integer with $w^{n_i}(i) = i$. We say that $(w, \mu)$ is good if for all $i$,

$$
\sum_{k \mod n_i} \mu_w(i)^k q^k \not\equiv 0 \pmod{\frac{q^{n_i} - 1}{q - 1}}
$$

for all $d | n_i$, $d \neq n_i$.

**Proposition 6.21.** Suppose that $(w, \mu) \in W \times X(T)$. The pair $(T_w, \theta_{w,\mu})$ is maximally split if and only if $(w, \mu)$ is good.

**Proof.** As described above, the dual pair is $(T_{F^*}^{w-1}, s_{w,\mu})$ where $s_{w,\mu} = g_{F^*}^{w-1} N_{(F^* w^{-1})/F^* w^{-1}}(\bar{\mu}(\zeta_{q^t-1}))$ ($t$ and $\bar{\mu}$ as before). Note that if $T^* \subset G^*$ is an $F^*$-stable maximal torus of type $\sigma \in W \cong S_n$, then the $F$-rank of $T^*$ is the number of orbits of $\sigma$ on $\{1, \ldots, n\}$ (Recall that $T$ and $T^*$ are split.)

**Sublemma 6.22.** Suppose $s \in G^{F^*}$ semisimple. Then $s$ lies in some $F^*$-stable maximal torus of type $\sigma$ iff $F^*(s') = \sigma^{-1}(s')$ for some $G^*$-conjugate $s' \in T^*$ of $s$.

**Proof.** If $s \in T^*$ of type $\sigma$ then there is a $g \in G^*$ such that $T^* = gT^*$ and $g^{-1}F^*(g)$ is a lift of $\sigma$ in $N(T^*)$. Note that $s' := g^{-1}s$ works.

For the other direction we can reverse the argument just given to see that there is a $G^*$-conjugate $s_0 \in T^* F^*$ of $s$ for some $F^*$-stable maximal torus $T^*$ of type $\sigma$. Writing $s = h s_0$ for some $h \in G^*$, it follows that $h^{-1}F^*(h) \in Z_{G^*}(s_0)$ which is connected reductive. By Lang’s theorem $h^{-1}F^*(h) = z^{-1}F^*(z)$ for some $z \in Z_{G^*}(s_0)$. Then $s \in h z^{-1} T^*$ which is of type $\sigma$ as $hz^{-1} \in G^{F^*}$.

It follows that $(T_w, \theta_{w,\mu})$ is maximally split iff whenever $F^*(s_{w,\mu}^') = \sigma^{-1}(s_{w,\mu}')$ for a $G^*$-conjugate $s_{w,\mu}^' \in T^*$ of $s_{w,\mu}$ then $\sigma$ has at most as many orbits on $\{1, \ldots, n\}$ as $w$. As $G^*$-conjugate elements in $T^*$ are $W$-conjugate [DM91 0.12(iv)], we need only consider $s'_{w,\mu} = N_{(F^* w^{-1})/F^* w^{-1}}(\bar{\mu}(\zeta_{q^t-1}))$, which equals $\left(\begin{array}{c} x_1 \\ \vdots \\ x_n \end{array}\right)$ for some $F$-stable sub-multiset $\{x_i\}_{i=1}^n$ of $\overline{\mathbb{F}}_p^\times$. 

If \( F^*(s'_{w,\mu}) = \sigma^{-1}(s'_{w,\mu}) \) then for all \( i \) and all \( k \), \( F^k(x_i) = x_i \) whenever \( \sigma^k(i) = i \). It follows that such a \( \sigma \) has the maximal number of orbits iff
\[
\forall i \forall k, \ F^k(x_i) = x_i \iff \sigma^k(i) = i.
\]
Thus \( (T_w, \theta_{w,\mu}) \) is maximally split iff for all \( i \), \( \sum_{j=0}^{m} \mu_j q^{i-j} \) is in no proper subfield of \( \mathbb{F}_{q^n} \), i.e., iff \( (w, \mu) \) is good.

Using lemmas \([4.4, 4.7]\) this implies:

**Corollary 6.23.** The image of the map \( V \) consists precisely of parabolic inductions of cuspidal representations.

For example, if \( n = 3 \), \( w = (1 \ 2 \ 3) \) and \( \mu = (i, j, k) \) then \( (w, \mu) \) is good iff \( m := i + qj + q^2k \neq 0 \pmod{q^2 + q + 1} \). In this case
\[
\tau(w, \mu) \sim \left( \omega_3^m \omega_3^m q^m \omega_3^{2m} \right)
\]
and \( R_w(\mu) \) is a cuspidal representation of \( GL_3(\mathbb{F}_q) \) \([4.4]\).

6.5. **The generic case.** The following basic lemma will be proved below.

**Lemma 6.24.** Suppose that \( \mu \in X(T) \) lies sufficiently deep in \( C_0 \). Then \( (w, \mu) \) is good.

**Definition 6.25.** Suppose that \( \tau : I_p \rightarrow GL_n(\mathbb{F}_p) \) is tame and that it can be extended to \( G_p \). Then \( \tau \) is said to be \( \delta \)-generic if \( \tau \cong \tau(w, \mu) \) for some good \( (w, \mu) \in W \times X(T) \) such that \( \mu \) is \( \delta \)-deep in \( C_0 \).

Recall that by lemma \([4.2]\) and prop. \([6.15]\) \( (w, \mu) \) in the definition is well defined up to the \( X(T) \times W \)-action \([4.1]\) which can be stated as
\[
(\nu, \sigma)(w, \mu) = (\sigma w \sigma^{-1}, (\sigma \cdot \mu + p\nu) + \nu),
\]
where \( \nu = \rho' - \sigma \rho' - \sigma w \sigma^{-1} \nu \). Fix for now \( (w, \mu) \) with \( \mu \in C_0 \). Consider the set \( \{ \sigma \cdot \mu + p\nu : (\nu, \sigma) \in X(T) \times W \} \). Modulo \( pX^0(T) \), it contains precisely \#\( W_1 = n \) weights in each alcove. To see this, note that \( \sigma \cdot \mu + p\nu \in C_0 \) iff \( (w, \mu) \) is in \( W_1 \) and \( \nu \in \rho'_\alpha + X^0(T) \) \([5.1]\), that \( W_1 \) acts transitively on the set of alcoves, and that no non-trivial element of \( W_1 \) fixes any weight in \( C_0 \).

Fix any alcove \( C \) and let us always assume for now that \( \mu \) is sufficiently deep in \( C_0 \) (the implied constant might depend on the statement). Consider the set of weight coordinates of the \( X(T) \times W \)-orbit of \( (w, \mu) \),
\[
\{ \sigma \mu + (p - \sigma w \sigma^{-1}) \nu : (\nu, \sigma) \in X(T) \times W \}.
\]
We claim that modulo \( (p - 1)X^0(T) \), this set contains precisely \#\( W_1 = n \) weights in \( C \).

First of all let us show that \( \mu' := \sigma \mu + (p - \sigma w \sigma^{-1}) \nu \in C \) if and only if \( \sigma \cdot \mu + p\nu \in C \). There exist \( n_\alpha \in \mathbb{Z} \) for \( \alpha \in R \) such that \( \eta \in C \) implies that \( |\langle \eta + \rho', \alpha^\vee \rangle| < n_\alpha p \) for all \( \alpha \). Thus we may even assume that \( |\langle \eta, \alpha^\vee \rangle| \leq \ldots \).
To see this, let \( \text{converse is much easier.} \)

To the boundary of \( \sigma \) in the same alcove as allows us to assume that for all those values of \( \nu \) Jantzen’s decomposition formula (5.2) (see the discussion on p. 15) shows then that the highest weights of all the constituents of \( \tau \). Suppose that \( \tau \) is sufficiently deep in a restricted alcove, \( \lambda \) is sufficiently deep in a restricted alcove, \( \lambda' \uparrow \lambda \) and some \( w' \in W \).

**Proposition 6.26.** Suppose that \( \tau : I_p \to GL_n(\mathbb{F}_p) \) is tame, can be extended to \( G_p \) and that \( \lambda \in X_1(T) \). Suppose either that (a) \( \tau \) is sufficiently generic or (b) \( \lambda \) is sufficiently deep in a restricted alcove. Then

\[
F(\lambda) \in W^?(\tau)
\]

if and only if

\[
\tau \cong \tau(w', \lambda' + \rho) \text{ for some } \lambda' \in X(T)_+ \text{ such that } \lambda' \uparrow \lambda
\]

and some \( w' \in W \).

**Proof.** We will first show the result under assumption (a), then we will show how (b) reduces to (a).

Write \( \tau \cong \tau(w, \mu + \rho) \). If \( \mu \) lies sufficiently deep in \( C_0 \), we may assume by (6.24) that \( (w, \mu + \rho) \) is good and by (5.6) that \( W^?(\tau) \) consists of the \( F(\lambda) \) with \( \lambda \in X_1(T) \) such that there exists a dominant \( \lambda' \uparrow \lambda \) satisfying

\[
\exists (\sigma, \nu) \in W \times X(T), \lambda' = \sigma \cdot (\mu + (w - p)\nu).
\]

From (4.1) it follows that (6.27) is equivalent to

\[
\exists w' \in W, (w, \mu + \rho) \sim (w', \lambda' + \rho).
\]

Finally, as this \( X(T) \times W \)-orbit is good by the choice of \( \mu \), this is equivalent to

\[
\exists w' \in W, \tau(w, \mu + \rho) \cong \tau(w', \lambda' + \rho).
\]

To reduce (b) to (a), suppose the proposition holds if \( \tau \) is \( \epsilon \)-generic. Suppose that \( \tau \) is not \( \epsilon \)-generic. Using the discussion after (6.25) there is a \( \delta > 0 \) such that \( \tau \cong \tau(w, \mu + \rho) \) for some \( w \in W \) and \( \mu \) which is \( \delta \)-close to the boundary of \( C_0 \) (that is, \((\delta)\)-deep but not \( \delta \)-deep). The analysis of Jantzen’s decomposition formula (5.2) (see the discussion on p. 15) shows then that the highest weights of all the constituents of \( R_w(\mu + \rho) \)—and thus the highest weights of the Serre weights in \( W^?(\tau) \)—are \( \delta' \)-close to the boundary of some restricted alcove for some \( \delta' > 0 \) depending on \( \delta \). Therefore if \( \lambda \) is sufficiently deep in a restricted alcove, \( F(\lambda) \in W^?(\tau) \) implies that \( \tau \) is
\(\epsilon\)-generic. By restricting \(\lambda\) yet further in its alcove, we can moreover achieve that for any \(\lambda' \uparrow \lambda\) with \(\lambda'\) dominant and any \(w' \in W\), \(\tau(w', \lambda' + \rho)\) is \(\epsilon\)-generic.

**Corollary 6.28.** Suppose that \(\tau\) is sufficiently generic. Then

\[\#W^\tau(\tau) = \#W_1 \cdot \#\{(C', C) : C' \text{ dominant, } C \text{ restricted, and } C' \uparrow C\},\]

where \(C'\) and \(C\) denote alcoves. Note that \(\#W_1 = n\).

In particular, the number of weights predicted in the generic case is \(2, 9, 88, 1640, \ldots\) if \(n\).

**Proof.** Write \(\tau \cong \tau(w, \mu + \rho)\) with \(\mu\) sufficiently deep in \(C_0\). Note first that if \(\epsilon \in (p - 1)X^{0}(T)\) then \(w', \lambda' + \rho) \sim (w', \lambda' + \epsilon + \rho), F(\lambda) \cong F(\lambda + \epsilon)\) and \(\lambda' \uparrow \lambda\) implies \(\lambda' + \epsilon \uparrow \lambda + \epsilon\). Thus we only need to consider the \(\lambda'\) in the proposition up to \((p - 1)X^{0}(T)\).

It suffices by the argument after (6.25) to prove the following statement.

\[(6.29)\quad \text{Suppose that } \tau \cong \tau(w_i, \lambda'_i + \rho)\text{ with } \lambda'_i \text{ dominant and } \lambda'_i \uparrow \lambda\text{ for some restricted weight } \lambda\text{ (}i = 1, 2\). Then } w_1 = w_2 \text{ and } \lambda'_1 = \lambda'_2.\]

We can write \(w_i = \sigma_i w_i^{-1}, \lambda'_i = \sigma_i : \mu + (p - \sigma_i w_i^{-1})\nu_i\) for some \((\nu_i, \sigma_i) \in X(T) \times W\). It follows immediately that \(S(\lambda) = S(\lambda'_i) = S(\mu) + (p - 1)S(\nu_i)\) so that \(S(\nu_1) = S(\nu_2)\). As the \(\lambda'_i\) are in the same \(W_p\)-orbit by assumption, so are the \(\mu + (p - w)\sigma_i^{-1}\nu_i\). As \(\sigma_i^{-1}\nu_1 - \sigma_i^{-1}\nu_2 \in \mathbb{Z}R\) (being killed by \(S\)), the weights \(\mu + p\sigma_i^{-1}\nu_2 - w\sigma_i^{-1}\nu_1\) are in the same \(W_p\)-orbit. But as they lie in the same alcove \(C_0 + p\sigma_i^{-1}\nu_2\), they have to be equal and we obtain that \(\sigma_i^{-1}\nu_1 = \sigma_i^{-1}\nu_2\). Finally, \(\sigma_i : C_0 + p\nu_i\) are dominant alcoves which are related by \(\sigma_i\) in \(W\). Thus \(\sigma_1 = \sigma_2\), which implies the claim. \(\square\)

**Proof of lemma 6.22.** If \(\mu = \sum a_i \epsilon_i\), note that \(\sum_{j=1}^{r} a_i \epsilon_j\) is in the lowest alcove for \(GL_n\), whenever \(1 \leq i_1 < \cdots < i_r \leq n\). We are thus reduced to the case when \(w\) is an \(n\)-cycle. We need to show that if \(\mu\) is sufficiently deep in \(C_0\),

\[(6.30)\quad \sum_{i \mod n} a_{w(1)} p^i \equiv 0 \pmod{p^n - 1} \quad \text{for all } d \mid n, \, d \neq n.\]

Fix \(n = de\) with \(d < n\). Using

\[\frac{p^n - 1}{p^d - 1} = \sum_{j=0}^{d(e-1)-1} p^{dj},\]

equation (6.30) becomes

\[(6.31)\quad \sum_{i=0}^{d(e-1)-1} (c_i - c_{d(e-1)+d(\{\frac{i}{d}\})}) p^i \equiv 0 \pmod{\sum_{j=0}^{d(e-1)-1} p^{dj}},\]

where \(c_i = a_{w(1)}\) and \(\{x\} \in [0, 1)\) denotes the fractional part of a real number \(x\). As \(\mu\) is in the lowest alcove, \(|c_i - c_j| \leq p - 1\) for all \(i, j\). So if \(\mu\)
lies sufficiently deep in $C_0$ then $c_i \neq c_j$ for all $i \neq j$ and (6.31) is automatic as $(p - 1)(1 + p + \cdots + p^i) < p^{i+1}$ for all $i$. \qed

7. Comparison with the ADPS conjecture ($n = 3$)

The framework of the conjecture used here differs slightly from that of \cite{ADP02}—we prefer to use left cosets, left actions and to ignore the nebentype character. First we explain how to relate them. When comparing the weight predictions, note that the conjecture in \cite{ADP02} is stated for general $n$ and for odd Galois representations $\rho$ that are neither necessarily tame at $p$ (at least in niveau 1) nor irreducible. For irreducible $\rho$, their predictions only depend on $\rho|_{I_p}$. We will restrict to the irreducible, tame-at-$p$ case to compare with our conjecture, and we will assume that $n = 3$, the case they studied in detail. (For larger $n$ in generic cases their weights will all be predicted here, but the discrepancy grows with $n$, even if Doud’s extension in the niveau $n$ case \cite{Dou07} is taken into account.) We will moreover interpret their recipe in the most favourable way, that is, include the “extra weights” described in \cite{ADP02}, def. 3.5. We should point out though that \cite{ADP02} never claims to predict all possible weights.

Let $\tilde{\Gamma}_1(N)$ be the group of matrices in $SL_n(\mathbb{Z})$ with first row congruent modulo $N$ to $(1, 0, \ldots, 0)$, and let $\tilde{S}_1'(N) \subset GL_n^+(\mathbb{Z}(N_p))$ be defined by the same congruence condition. Then $\tilde{H}_1'(N)$ is the Hecke algebra defined by the Hecke pair $(\tilde{\Gamma}_1(N), \tilde{S}_1'(N))$, but instead of left cosets (as in §2.1) using right cosets. If the congruence condition is weakened to the first row being $(*, 0, \ldots, 0)$ modulo $N$, the corresponding objects are denoted by $\tilde{\Gamma}_0(N)$, $\tilde{S}_0'(N)$, $\tilde{H}_0'(N)$. Note that $(\tilde{\Gamma}_1(N), \tilde{S}_1'(N))$ and $(\tilde{\Gamma}_0(N), \tilde{S}_0'(N))$ are strongly compatible (§2.1).

Letting

$$\eta = \begin{pmatrix} \eta \end{pmatrix},$$

observe that $g \mapsto \eta^t g \cdot \eta^{-1}$ induces anti-isomorphisms of groups $\Gamma_i(N)$ to $\tilde{\Gamma}_i(N)$, $S_i'(N) \to \tilde{S}_i'(N)$, and of (commutative) algebras $H_i'(N) \to \tilde{H}_i'(N)$ ($i = 0, 1$).

A Serre weight $F$ (with usual left $S_1'(N)$-action) becomes a right $\tilde{S}_1'(N)$-module, denoted $\hat{F}$, as follows: $m\tilde{s} := \epsilon(\eta^{-1}\tilde{s}\eta)m$ ($m \in F$, $\tilde{s} \in \tilde{S}_1'(N)$, $i = 0, 1$). It is easy to see that with this action, $\hat{F}$ is a “right Serre weight” with the same highest weight. The following lemma is immediate.

**Lemma 7.1.** The above anti-isomorphisms induce an isomorphism

$$H^c(\Gamma_1(N), F) \cong H^c(\tilde{\Gamma}_1(N), \hat{F}),$$

as modules of $H_1'(N) \cong \tilde{H}_1'(N)$.

Any character $\epsilon : (\mathbb{Z}/N)^\times \to \mathbb{F}_p^\times$ can be considered as character of $\tilde{S}_0'(N)$ via its natural projection to $\tilde{S}_0'(N)/\tilde{S}_1'(N) \cong (\mathbb{Z}/N)^\times$. Let $\hat{F}(\epsilon) = \hat{F} \otimes \mathbb{F}_p(\epsilon)$.
Lemma 7.2. Fix a ring homomorphism
\[ \sigma : \tilde{\mathcal{H}}_1'(N) \cong \tilde{\mathcal{H}}_0'(N) \rightarrow \mathbb{F}_p. \]
The following are equivalent:
(i) There is an \( \tilde{\mathcal{H}}_1'(N) \)-eigenvector for \( \sigma \) in \( H^c(\tilde{\Gamma}_1(N), \tilde{F}) \) for some \( e \).
(ii) There is an \( \tilde{\mathcal{H}}_0'(N) \)-eigenvector for \( \sigma \) in \( H^c(\tilde{\Gamma}_0(N), \tilde{F}(e)) \) for some \( e \) and for some \( \epsilon : (\mathbb{Z}/N)^\times \rightarrow \mathbb{Q}_p^\times \).

Proof. Note that the proof is complicated by the fact that \( p \) could divide \( \phi(N) \).

If \( M \) is any \( \tilde{S}_0'(N) \)-module then \( (\mathbb{Z}/N)^\times \) acts naturally (and \( \delta \)-functorially) on \( H^c(\tilde{\Gamma}_1(N), M) \), commuting with the action of \( \tilde{\mathcal{H}}_1'(N) \) (as observed in [AS86, p. 196]). The Hochschild-Serre spectral sequence
\[ E_2^{p,q} : H^p((\mathbb{Z}/N)^\times, H^q(\tilde{\Gamma}_1(N), \tilde{F}(e))) \Rightarrow H^{p+q}(\tilde{\Gamma}_0(N), \tilde{F}(e)) \]
is compatible with the action of \( \tilde{\mathcal{H}}_1'(N) \cong \tilde{\mathcal{H}}_0'(N) \). The reason is that the Grothendieck spectral sequence for a composition \( F_1 \circ F_2 \) is compatible with natural transformations \( F_2 \rightarrow F_3 \) since the spectral sequences for the hyper-derived functors \( (\mathcal{R}^2F_1)(C) \) are functorial in the cochain complex \( C \) [Gro57, §2.4].

If \( M \) is any \( \tilde{\mathcal{H}}_1'(N) \)-module, denote by \( M_\sigma \) the generalised \( \sigma \)-eigenspace.

Supposing (ii), considering the generalised \( \sigma \)-eigenspace of the above spectral sequence we find that \( (E_2^{p,q})_\sigma \neq 0 \) for some \( p, q \), whence (i). (All terms of the spectral sequence are finite-dimensional; see p. 35)

Conversely, assuming (i), pick \( q \) smallest such that \( H^q(\tilde{\Gamma}_1(N), \tilde{F})_\sigma \neq 0 \). Observing that
\[ H^q(\tilde{\Gamma}_1(N), \tilde{F}(e)) \cong H^q(\tilde{\Gamma}_1(N), \tilde{F}(\epsilon)) \]
as \( (\mathbb{Z}/N)^\times \)-module, we can choose \( \epsilon \) so that \( H^q(\tilde{\Gamma}_1(N), \tilde{F}(\epsilon))_\sigma \) has a \( (\mathbb{Z}/N)^\times \)-fixed vector. By the minimality of \( q \), \( (E_\infty^{p,q})_\sigma \neq 0 \), whence (ii). \( \Box \)

For simplicity we will say that a Serre weight \( F(\lambda) \) (\( \lambda \in X_1(T) \)) is in the lower alcove \( C_0 \) if \( \lambda \in C_0 \). If \( F(\lambda) \) is a regular Serre weight, we will use the notation \( ^rF(\lambda) := F(^r\lambda) \) with \( (\lambda \mapsto ^r\lambda) \in W_p \) as on p. 10 (Note that both definitions do not actually depend on any choices.)

Definition 7.3. For \( \lambda \in X_1(T) \) let \( \mathcal{A}(\lambda) \) be the set of regular Serre weights consisting of \( F := F(\lambda - \rho)_{reg} \) and, in case \( F \in C_0 \), also \( ^rF \in C_1 \).

The next result should be compared with (6.26).

Proposition 7.4. Suppose that the tame inertial Galois representation \( \tau : I_p \rightarrow GL_n(\mathbb{Q}_p) \) can be extended to \( G_p \). Let
\[ C(\tau) = \{ \lambda \in X_1(T) : \exists w \in W, (w, \lambda) \text{ good and } \tau \cong \tau(w, \lambda) \}. \]

Then
\[ W^\tau(\tau) = \bigcup_{\lambda \in C(\tau)} \mathcal{A}(\lambda). \]
It will become clear from the proof that for sufficiently generic \( \tau \), \( C(\tau) \) consists of three weights each in the upper and the lower alcove. We will use the following lemma.

**Lemma 7.6.** (i) If \( \tau \sim \left( \omega^j \omega^i \omega^k \right) \) with \( i \geq j \geq k \), \( i - k \leq p - 1 \),
\[
C(\tau) = \{(i,j,k), (j,k,i - p + 1), (k + p - 1, i,j), (k + p - 1, j,i - p + 1), (i,k,j - p + 1), (j + p - 1, i,k)\} + (p - 1)X^0(T).
\]
(ii) If \( \tau \sim \left( \omega^{m}_2 \omega^{m}_2 \omega^{m}_2 \right) \) with \( m = j + pk \) and \( i \geq j > k \), \( i - k \leq p - 1 \),
\[
C(\tau) = X_1(T) \cap \{(i,j,k), (j,k,i - p + 1), (k + p, i,j - 1), (k + p,j - 1, i - p + 1), (i,k + 1, j - p), (j + p, i,k - 1), (i + p - 1, j,k), (j,k,i - 2p + 2)\} + (p - 1)X^0(T).
\]
(iii) If \( \tau \sim \left( \omega^{m}_3 \omega^{m}_3 \omega^{m}_3 \right) \) with \( m = i +pj + p^2k \) and \( i \geq j \geq k \), \( i - k \leq p \),
\[
C(\tau) = X_1(T) \cap \{(i,j,k), (j + 1, i,k - p), (k + p, i - 1, j), (k + p, j + 1, i - p - 1), (i,k + 1, j - p), (j + p, i,k - 1)\} + (p - 1)X^0(T).
\]

**Proof.** Suppose that \( \lambda = (x',y',z') \in C(\tau) \).

(i) By (6.15) and (1.2), \( \tau \equiv \tau(w, \lambda) \) with \( (w, \lambda) \) good implies that \( (w, \lambda) \sim (1, (i,j,k)) \). Thus there is a permutation \((x,y,z)\) of \((x',y',z')\) such that \( x \equiv i \), \( y \equiv j \), \( z \equiv k \) (mod \( p - 1 \)). This is invariant under the change of coordinates
\[
\theta : (x,y,z;i,j,k) \mapsto (z,x,y;k + p - 1,i,j).
\]
We may assume without loss of generality that \( y > j \geq z \) or \( x < y < z \). In the first case, \((x',y',z') = (x,y,z)\). It is then evident that precisely the following weights are obtained: \((i,j,k)\), \((i + p - 1,j,k) = (j + p - 1,i,k) \) (if \( i = j \)), \((i,j,k - p + 1) = (i,k,j - p + 1)\) (if \( i = j + 1 \)), \((i + p - 1,j,k - p + 1) = (k + p - 1,j,i - p + 1) \) (if \( i = j \)).

The second case is analogous, yielding precisely \((k + p - 1,j,i - p + 1)\) (due to the inequalities being strict).

(ii) Here there is a permutation \((x,y,z)\) of \((x',y',z')\) such that \( x \equiv i \) (mod \( p - 1 \)), \( y +pz \equiv m \) (mod \( p^2 - 1 \)). Without loss of generality, \( y +pz = j + pk \). Note that \( |y - z| \leq 2p - 2 \). Thus \((y,z) = (j,k) + n(p, -1)\) with \(-2 \leq n \leq 1\).

If \( n = -2 \): since \( j - 2p < 2p + 2 < i - p + 1 < k + 2 \), this can’t happen.

If \( n = -1 \): use that \( y = k + 1 > i - p + 1 > j - p = z \) to get one of \((i,k + 1,j,p)\), \((k + 1,i - p + 1,j,p)\) or \((k + 1,j - p,i - 2p + 2)\).

If \( n = 0 \), at most \((i + p - 1,j,k)\), \((i,j,k)\), \((j,k,i - p + 1)\), \((j,k,i - 2p + 2)\) arise.

If \( n = 1 \), the only possibility is \((j + p,i,k - 1)\), since \((j + p) - (k - 1) > p - 1\) and \( j + p > i > k - 1 \).
(iii) Here there is a permutation \((x, y, z)\) of \((x', y', z')\) such that \(x + py + p^2 z \equiv m \pmod{p^3 - 1}\). This is invariant under the change of coordinates \(\theta' : (x, y, z; i, j, k) \mapsto (z, x, y; k + p, i - 1, j)\). So, without loss of generality, either \(x \geq y \geq z\) or \(x < y < z\).

In the first case, \((x', y', z') = (x, y, z)\). Without loss of generality, \(A + pB + p^2 C = 0\), with \(A = x - i\), \(B = y - j\), \(C = z - k\). Noting that

\[
|A - C| = |(x - z) - (i - k)|
\]

\[
\leq \max(p, 2p - 3) \leq 2p - 2,
\]

it follows that

\[
|(1 + p + p^2)C| = |(A - C) + p(B - C)| \leq p^2 + p - 2.
\]

Thus \(C = 0\), and \(A + pB = 0\) implies

\[
|(1 + p)B| = |A - B| \leq p
\]

and hence \(B = A = 0\). So, \((x', y', z') = (i, j, k)\).

In the second case, a completely analogous argument shows that \((x', y', z') = (k + p, j + 1, i - p - 1)\).

\[\square\]

**Proof of prop. 7.4.** First note that, for \(\lambda \in X_1(T)\),

\[
\mathcal{R}(JH(W(\lambda)))
\]

consists of \(F := \mathcal{R}(F(\lambda))\) and, if \(F \in C_0\), also \(^* F\). Also note that for \((x', y', z') \in X_1(T)\), \(F(x' - 2, y' - 1, z')_{\text{reg}} = \mathcal{R}(F(z' + p - 1, y', x' - p + 1))\) (note that the latter weight is also restricted). Thus

\[
(7.7) \quad A(x', y', z') = \mathcal{R}(JH(W(z' + p - 1, y', x' - p + 1))).
\]

With the convention that \(A(\lambda) := \emptyset\) \((\lambda \notin X_1(T))\), \(\mathcal{R}(0) := \emptyset\), (7.7) is even true for any \((x', y', z') \in X(T)\) satisfying \(x' - y' = p\) or \(y' - z' = p\) or \(x' - z' = 2p\) (by (3.5)).

If \(\tau \cong \tau(1, (i, j, k)) \sim (\omega_i^m \omega_j^m \omega_k^m)\), without loss of generality, \(i \geq j \geq k\), \(i - k \leq p - 1\). By thm. 5.2, \(R_1(i, j, k)\) equals

\[
W(k + p - 1, j, i - p + 1) + W(i, k, j - p + 1) + W(j + p - 1, i, k) + W(i, j, k) + W(j, k, i - p + 1) + W(k + p - 1, i, j).
\]

The lemma follows from (7.7), term by term.

If \(\tau \cong (\omega_i^{2m} \omega_j^{2m} \omega_k^{2m})\), we can write \(m = j + pk\) with (unique) \(i \geq j > k\), \(i - k \leq p - 1\) (replacing \(m\) with \(pm\) if necessary). Then \(\tau \cong \tau((2 \ 3), (i, j, k))\) and \(R_{(2\ 3)}(i, j, k)\) equals

\[
W(k + p - 1, j, i - p + 1) + W(i, k, j - p + 1) + W(j + p - 2, i, k + 1) + W(i, j - 1, k + 1) + W(j - 1, k + 1, i - p + 1) + W(k + p - 2, i, j + 1).
\]
Note that the last two weights in the lemma do not contribute (e.g., for 
\((i + p - 1, j, k)\) to occur we need \(i = j\) in which case \(F(i+p-3, j-1, k)_{\text{reg}} = F(i-2, j-1, k)_{\text{reg}}\). The remaining six weights \((x', y', z')\) all verify \(x' - y' = y' - z' \in [0, p]\). The lemma follows from (7.7), term by term.

If \(\tau \sim \left(\begin{array}{c} \omega_2^m \\ \omega_2^{pm} \\ \omega_3^m \end{array}\right)\), a simple exercise shows that either \(m\) or \(-m\)
equals \(i + pj + p^2k\) for some \((\text{unique})\) \(i \geq j \geq k\), \(i - k \leq p\). In the first case, \(\tau \cong \tau((1 2 3), (i, j, k))\) and \(R((1 2 3))(i, j, k)\) equals
\[
W(k + p - 1, j, i - p + 1) + W(i - 1, k, j - p + 2)
\]
\[
+ W(j + p - 1, i - 1, k + 1) + W(i - 2, j + 1, k + 1)
\]
\[
+ W(j - 1, k + 1, i - p + 1) + W(k + p - 2, i, j + 1).
\]
(7.8)
Everything works as in the previous situation, except that the fourth through
the sixth weight in the lemma can fail to be restricted by having their second
and third coordinate differ by \(p + 1\). Using the cyclic symmetry \(\theta^j\) exploited
in the lemma, we may assume without loss of generality that \(i = k + p\) and
\(i \neq j + 1\) (because not all three equalities can hold simultaneously).
Then we can already match the first four terms of (7.8) with the first four weights
in the lemma using (7.7). This is even true for the fifth: that weight in the
lemma fails to be restricted if \(j - k \leq 1\) and then either \(y' - z' = p\) or \(x' - z' = 2p\). If \(j - k = p - 1\) the same argument works for the sixth also,
so let us assume that \(j - k < p - 1\).

Note that term 6 in (7.8) equals \(-F(i-1, k+p-1, j+1)\) (by (3.5)) which
cancels the irreducible constituent in \(C_0\) of the reducible \(W(j + p - 1, i - 1, k + 1)\) (term 3). We will be done if we show that \(R(F(i - 1, k + p - 1, j + 1))\)
is contained in the union of \(R(JH(W))\) where \(W\) runs over terms 1, 2, 4, 5 in (7.8). Term 2 suffices:
\[
R(F(i - 1, k, j - p + 2)) = R(F(i - 1, k + p - 1, j + 1)).
\]
In the second case, we dualise: in light of prop. (6.10) we only have to show that
\(C(\tau') = \{-w_0 \lambda : \lambda \in C(\tau)\}\) and that \(\bar{\tau}\) and \(\bar{\tau}\) commute on regular Serre
weights, but this is obvious.

\[\square\]

Theorem 7.9.

(i) If \(\tau\) is of niveau 1, the regular Serre weights predicted in [ADP02] agree
exactly with the ones here.

(ii) If \(\tau\) is of niveau 2, we can write \(\tau \sim \left(\begin{array}{c} \omega_2^m \\ \omega_2^{pm} \\ \omega_3^m \end{array}\right), with m = j + pk\)
and \(i \geq j > k, i - k \leq p - 1\) (up to swapping \(m\) and \(pm\)). Then
the regular Serre weights predicted in [ADP02] are precisely the ones given by
formula (7.5) when the sixth weight on the list in lemma (7.6) (ii) is removed.

(iii) If \(\tau\) is of niveau 3, we can write \(\tau \sim \left(\begin{array}{c} \omega_3^n \\ \omega_3^{pm} \\ \omega_3^{2m} \end{array}\right)\) with \(m = i + pj + p^2k\) and \(i > j \geq k, i - k \leq p\) (up to dualising \(\tau\)). Then the regular Serre
weights predicted in [ADP02] are precisely the ones given by formula (7.5)
when the following weights are removed from the list in lemma 7.6 (iii): the last three and those among the first three of the form \((x',y',z')\) with \(x' - z' = p\) and \(x' - 1 > y' > z'\).

**Proof.** We use the explicit description of \(C(\tau)\) in terms of congruences as in the proof of 7.6

(i) This is obvious.

(ii) Note that according to [ADP02] we write \(m = j + pk\) (note that \(0 \leq j - k \leq p - 1\) and \(pm \equiv (k + p) + p(j - 1) \pmod{p^2 - 1}\) (note that \(0 \leq (k + p) - (j - 1) \leq p - 1\) unless \(j = k + 1\), in which case \(pm\) cannot be expressed in this way). So the regular weights predicted there are \(F(i-2,j-1,k)_{\text{reg}}, F(j-2,i-1,k)_{\text{reg}}, F(j-2,k-1,i)_{\text{reg}}\) and, if \(j \neq k + 1\), \(F(i-2,k+p-1,j-1)_{\text{reg}}, F(k+p-2,i-1,j-1)_{\text{reg}}, F(k+p-2,j-2,i)_{\text{reg}}\) together with the reflections \(\tau F\) for any \(F\) in this list that is in the lower alcove. Suppose first that \(j \neq k + 1\). As \(F := F(k+p-2,i-1,j-1) \in C_0\) and \(\tau F = F(j-2,i-1,k)_{\text{reg}}\), the latter weight is redundant in the list just given and we obtain the union of \(A(i,j,k), A(j,k,i-p+1), A(i,k+1,j-p),\)

\(A(k+p,i,j-1), A(k+p,j-1,i-p+1)\) as required. If \(j = k + 1\), the fourth and fifth weight in lemma 7.6 (ii) fail to be restricted and we can match up the three terms on the list just given with the first three weights in the lemma by noting that \(F(j-2,i-1,j-1)_{\text{reg}} = F(k+p-2,i-1,j-1)_{\text{reg}}\).

(iii) Let \(\alpha := p - (i - k), \beta := j - k, \gamma := i - j - 1\). These are permuted by \(\theta'\) from the proof of lemma 7.6 (iii) and we can assume without loss of generality that either (a) \(\alpha, \beta, \gamma\) are all non-zero, (b) \(\alpha = 0\) and the other two non-zero, or (c) \(\alpha = \beta = 0, \gamma \neq 0\). Note that one of the first three weights in the lemma will be excluded by the condition in the theorem if we are in case (b) in which case precisely \((i,j,k)\) is affected.

If (a) holds, we write \(m = i + pj + p^2k, pm \equiv (k + p) + p(i - 1) + p^2j \pmod{p^3 - 1}, p^2m \equiv (j + p) + p(k + p - 1) + p^2(i - 1) \pmod{p^3 - 1}\). So the regular weights predicted by [ADP02] are \(F(i-2,j-1,k)_{\text{reg}}, F(k+p-2,i-2,j)_{\text{reg}}\) for any \(F\) in this list that is in the lower alcove. Now note that the first three weights in the lemma are all restricted.

If (b) holds, the expression for \(m\) we have to use is \(m = k + p(j + 1) + p^2k\) and the weights predicted by [ADP02] are as in (a) except that the first becomes \(F(j-1,k-1,k)_{\text{reg}}\) which equals the third. On the other hand, we should only use the second and the third weights of the lemma, and we are fine as both are restricted.

If (c) holds, the expressions for \(m\) and \(p^2m\) are as in (b) whereas \(pm\) does not have an expression of the required form. We are fine again as precisely the first weight among the first three in the form \(\tau F\) for any \(F\) in this list that is in the lower alcove.

Remark 7.10. Doud independently extended the conjecture of [ADP02] to include the remaining weights in niveau 3 predicted here [Dou07].
8. Computational evidence for the conjecture

8.1. Verification of “extra weights”. In [ADP02], Ash, Doud and Pollack consider various explicit irreducible, odd $\rho$ that are tame at $p$ and test computationally whether eigenclasses to which $\rho$ is attached occur in the weights predicted by them (in level $N^z(\rho)$ and nebentype determined by $\det(\rho)$; see [ADP02] p.524). Among them are seven examples of such $\rho$ of niveau 2, for which conjecture [6.3] predicts one further weight than the ADPS conjecture. There is another such example in [Dou02, §3]. Darrin Doud and David Pollack agreed to test with their respective computer programs the existence of an eigenclass with the correct eigenvalues in this “extra weight.” They indeed verified its existence (in the sense that (6.4) is satisfied for all $l \leq 47$) except in the one case of level $N = 144$, which could not be handled by their programs.

To summarise, here is a table of the extra weight confirmed in each case:

| $p$ | level(s) $N$ | $\rho|I_p$ | weight |
|-----|-------------|------------|--------|
| 5   | 73, 83, 89, 151, 157 | $\left( \begin{array}{c} \omega_2^{3} \\ \omega_2^{16} \\ 1 \end{array} \right)$ | $F(6, 3, 0)$ |
| 7   | 67          | $\left( \begin{array}{c} \omega_2^{12} \\ \omega_2^{36} \\ \omega_3 \end{array} \right)$ | $F(13, 8, 3)$ |
| 11  | 17          | $\left( \begin{array}{c} \omega_2^{20} \\ \omega_2^{80} \\ 1 \end{array} \right)$ | $F(16, 9, 2)$ |

The image of $\rho$ in these cases is either $S_4$ ($N = 17, 67, 73$), $A_5$ ($N = 89, 151, 157$) or a suitable semi-direct product ($\mathbb{Z}/3 \times \mathbb{Z}/3) \rtimes S_3$ when $N = 83$ [ADP02], [Dou02].

8.2. Exhaustive calculations. In the example of niveau 73 listed above, Doud verified upon request that no eigenclasses to which $\rho$ is attached occur in regular weights outside $W^z(\rho|I_p)$ (as before, in level $N^z(\rho)$ and nebentype determined by $\det(\rho)$).

In [Dou07] §4, §5.2, §5.3, Doud documents similar exhaustive calculations for several (tame) $\rho$ of niveau 3. In one example only roughly half the weights are ruled out due to computational limitations. (As remarked in (7.10), the extension of the ADPS conjecture in [Dou07] for $\rho$ of niveau 3, which Doud found independently, agrees on the subset of regular weights with $W^z(\rho|I_p)$.)

9. Evidence for a conjecture of Gee

After an earlier version of this work [Her06], Toby Gee made another conjecture for the weights in this context in terms of the existence of local crystalline lifts with prescribed Hodge-Tate numbers (in the spirit of the Buzzard-Diamond-Jarvis conjecture). This type of conjecture is motivated by considerations in characteristic zero; the problem in making deductions for characteristic $p$ is that irreducible $GL_n$-modules in characteristic zero reduce to Weyl modules (up to semisimplification), generally not to simple
modules. Relying on the study of the $n = 3$ and $4$ cases in \cite{Her06}, he went on to make a second conjecture to the extent that $F \in W(\rho)$ implies $F(\lambda) \in W(\rho)$ whenever the Serre weight $F$ is a constituent of $W(\lambda)$ and $\lambda$ is restricted. This would give a better justification for his first conjecture for weights $F(\lambda)$ for which $W(\lambda) \neq F(\lambda)$.

We verify that Toby Gee’s second conjecture holds for the conjectural weight set $W^? (\rho | I_p)$ in generic situations.

**Proposition 9.1.** Suppose that $\lambda$ is sufficiently deep in a restricted alcove, $\lambda' \in X_1(T)$, and that $F(\lambda')$ is a Jordan-Hölder constituent of $W(\lambda)$ as representation of $GL_n(\mathbb{F}_p)$. Then for any tame $\tau : I_p \to GL_n(\mathbb{F}_p)$ that can be extended to $G_p$,

$$F(\lambda') \in W^? (\tau) \Rightarrow F(\lambda) \in W^? (\tau).$$

**Proof.** By 3.16, the constituents of $W(\lambda)$ as $GL_n$-module are of the form $F(\mu)$ for dominant $\mu \uparrow \lambda$. We can choose such a $\mu$ such that $F(\lambda')$ is constituent of $F(\mu)$ considered as representation of $GL_n(\mathbb{F}_p)$ and we write $\mu = \mu_0 + p\mu_1$ with $\mu_0 \in X_1(T), \mu_1 \in X(T)$. Note that for fixed $n$, $\mu_1$ can only take finitely many values. Let us write

$$\text{ch } F(\mu_1) = \sum_{\varepsilon \in X(T)} a_\varepsilon e(\varepsilon) \text{ with } a_\varepsilon \in \mathbb{Z}.$$

**Claim:** If $\lambda$ lies sufficiently deep in its alcove, then

$$F(\mu) = \sum_{\varepsilon \in X(T)} a_\varepsilon F(\mu_0 + \varepsilon)$$

in the Grothendieck group of $GL_n(\mathbb{F}_p)$-representations.

Restricting $\lambda$ in its alcove if necessary, we may assume that $\mu_0 + \varepsilon$ lies in the same alcove as $\mu_0$ whenever $a_\varepsilon \neq 0$. In the Grothendieck group of $GL_n$-modules we can write (using prop. 3.16)

$$F(\mu_0) = \sum_{\mu_0 \downarrow \mu_0} b_{\mu_0', \mu_0} W(\mu_0'),$$

where $b_{\mu_0', \mu_0} = 0$ if $\mu_0'$ is not dominant. Using thm. 3.9 and prop. 3.8 in the Grothendieck group of $GL_n(\mathbb{F}_p)$-modules,

$$F(\mu) = F(\mu_0) \otimes F(\mu_1)$$

$$= \sum_{\mu_0 \downarrow \mu_0} b_{\mu_0', \mu_0} W(\mu_0') \otimes F(\mu_1)$$

$$= \sum_{\mu_0 \downarrow \mu_0} \sum_{\varepsilon \in X(T)} a_\varepsilon b_{\mu_0', \mu_0} W(\mu_0' + \varepsilon)$$

$$= \sum_{\varepsilon \in X(T)} a_\varepsilon F(\mu_0 + \varepsilon).$$
The last step made use of the translation principle \cite[II.7.17(b)]{Jan03}, which implies that the $a_\varepsilon$ only depend on the alcoves $\mu'_0$ and $\mu_0$ lie in, and the fact that the $\alpha_\varepsilon$ depend only on the $W$-orbit of $\varepsilon$.

Using the claim, $F(\lambda') \cong F(\mu_0 + \varepsilon)$ for some weight $\varepsilon$ of $F(\mu_1)$ and some dominant $\mu \uparrow \lambda$. If $F(\lambda') \in W^\sigma(\tau)$, $\tau \cong \tau(w, \lambda'' + \rho)$ for some dominant $\lambda'' \uparrow \mu_0 + \varepsilon$ by prop.\ 6.26. But by the remark after (3.14) such a $\lambda''$ is of the form $\mu'_0 + w'\varepsilon$ for some dominant $\mu'_0 \uparrow \mu_0$ and some $w' \in W$ (in fact, $w'$ underlies the affine Weyl group element taking the alcove of $\mu'_0$ to the alcove of $\mu_0$). The following simple manipulation—using (4.1) and valid for all $\sigma \in W$—is the key point of the proof:

\[(9.2) \quad \tau \cong \tau(w, \mu'_0 + w'\varepsilon + \rho) \cong \tau(w, \mu'_0 + pw^{-1}w'\varepsilon + \rho) \cong \tau(\sigma w\sigma^{-1}, \sigma \cdot (\mu'_0 + pw^{-1}w'\varepsilon) + \rho).\]

We choose $\sigma \in W$ so that $\sigma \cdot (\mu'_0 + pw^{-1}w'\varepsilon)$ is dominant. Note that $\alpha_\varepsilon \neq 0$ implies that $\pi \varepsilon \leq \mu_1$ for all $\pi \in W$ \cite[II.2.4]{Jan03}. Then the following lemma applies and shows that

\[(9.3) \quad \sigma \cdot (\mu'_0 + pw^{-1}w'\varepsilon) \uparrow \mu'_0 \uparrow \mu_0 + \rho \mu_1 \uparrow \lambda\]

(using \cite[II.6.4(4)]{Jan03}). Finally apply prop.\ 6.26 to (9.2).

\section*{Lemma 9.4}

Suppose that $\mu, \nu \in X(T)_+$. If $\varepsilon \in X(T)$ such that $w\varepsilon \leq \nu$ for all $w \in W$ then

\[\sigma \cdot (\mu + p\varepsilon) \uparrow \mu + p\nu \quad \forall \sigma \in W.\]

\section*{Remark 9.5}

In fact the converse is true if $\mu \in C_0$ (but not in general).

\textbf{Proof.} We will use two reduction steps:

(R1) Suppose the lemma is true for $\varepsilon$ and that $\alpha \in R^+$ such that $\langle \varepsilon, \alpha^\vee \rangle \geq 0$. Then the lemma is true for $\varepsilon - i\alpha$ for all $0 \leq i \leq \langle \varepsilon, \alpha^\vee \rangle$.

(R2) Suppose that $\varepsilon \lesssim \nu$ are both dominant. Then there exists $\alpha \in R^+$ such that $\varepsilon \leq \nu - \alpha$ and $\nu - \alpha$ is dominant.

Assume first the validity of these two claims. Note that the lemma is true for $\varepsilon = \nu$ \cite[II.6.4(5)]{Jan03}. Suppose next that $\varepsilon$ is dominant. By (R2) there is a sequence $\varepsilon = \varepsilon_0 \leq \varepsilon_1 \leq \cdots \leq \varepsilon_r = \nu$ with $\varepsilon_j$ dominant and $\beta_j := \varepsilon_j - \varepsilon_{j-1} \in R^+$ for all $j > 0$. Note that $\langle \varepsilon_j, \beta_j^\vee \rangle = \langle \varepsilon_{j-1}, \beta_j^\vee \rangle + \langle \beta_j, \beta_j^\vee \rangle \geq 2$. Then (R1) with $i = 1$ implies inductively that the lemma is true for $\varepsilon$. Finally for a general $\varepsilon$ choose $w \in W$ such that $w\varepsilon$ is dominant. Write $w = s_1 \cdots s_r$, a reduced expression in terms of simple reflections $s_j$. A standard argument shows that then $\varepsilon = \varepsilon_r \leq \varepsilon_{r-1} \leq \cdots \leq \varepsilon_0 = w\varepsilon$ with $\varepsilon_j = s_{j+1} \cdots s_{r-1}s_r\varepsilon$. Since the lemma is true for $w\varepsilon$, (R1) with $i$ maximal allows to show inductively that the lemma is true for $\varepsilon$.

To prove (R1), choose $w \in W$ such that $\lambda := w \cdot (\mu + p\varepsilon) \in X(T)_+ - \rho'$. Then

$$0 \leq pi < \langle \mu + \rho', \alpha^\vee \rangle + p\varepsilon, \alpha^\vee \rangle = \langle \lambda + \rho', w\alpha^\vee \rangle.$$
In particular, \( \omega \alpha \in R^+ \). Then [Jan03, II.6.9] applies (note that the case \( i = 0 \) is vacuous and use [Jan03, II.6.4(5)]]:
\[
\sigma \cdot (s_{\omega \alpha} w \cdot (\mu + p \varepsilon) + p \omega \alpha) \uparrow \lambda \quad \forall \sigma \in W.
\]
Replacing \( \sigma \) by \( \sigma s_{\omega \alpha} w \) and using that the lemma holds for \( \varepsilon \) proves (R1):
\[
\sigma \cdot (\mu + p(\varepsilon - i \alpha)) \uparrow \mu + p \nu \quad \forall \sigma \in W.
\]
(R2) is also known as Stembridge’s lemma and is true for arbitrary root systems; see [Rap00, 2.3] for a short proof due to Waldspurger.

\( \square \)

10. THEORETICAL EVIDENCE FOR THE CONJECTURE

Recall that we assume that \( n > 1 \). Let \( \mathbb{A} := \mathbb{A}_Q \) and define
\[
U_1(N) := \{ g \in GL_n(\hat{\mathbb{Z}}) : \text{last row } \equiv (0, \ldots, 0, 1) \pmod{N} \},
\]
\[
\Sigma_1(N) := \{ g \in GL_n(\mathbb{A}^\infty) : g_N \in U_1(N) \},
\]
where \( g_N = \prod_{l|N} g_l \). Then \((U_1(N), \Sigma_1(N))\) is a Hecke pair, and we denote by \( H^1_\mathbb{A}(N) \) the associated Hecke algebra.

**Lemma 10.1.** There is an isomorphism of Hecke algebras
\[
H^1_\mathbb{A}(N) \cong H_1(N)
\]
determined by requiring that
\[
[U_1(N)sU_1(N)] \mapsto [\Gamma_1(N)s\Gamma_1(N)]
\]
for all \( s \in S_1(N) \).

**Proof.** It suffices to show that \((\Gamma_1(N), \Sigma_1(N)) \subset (U_1(N), \Sigma_1(N))\) are strongly compatible Hecke pairs (2.1). To see that \( S_1(N)U_1(N) = \Sigma_1(N) \), note that by strong approximation and as \( n > 1 \),
\[
GL_n(\mathbb{Q})U_1(N) = G(\mathbb{A}^\infty) \supset \Sigma_1(N),
\]
so for \( \sigma \in \Sigma_1(N) \) write \( \sigma = \gamma u \ (\gamma \in GL_n(\mathbb{Q}), u \in U_1(N)) \). Without loss of generality, set \( \gamma > 0 \). Then it follows immediately that \( \gamma \in S_1(N) \). Also, \( U_1(N) \cap S_1(N)^{-1} S_1(N) = \Gamma_1(N) \) is obvious.

Finally we need to show that \( U_1(N)sU_1(N) = \Gamma_1(N)sU_1(N) \) for all \( s \in S_1(N) \), or equivalently that \( U_1(N) = \Gamma_1(N)(U_1(N) \cap {}^sU_1(N)) \). As \( s_N \in U_1(N) \) and \( U_1(N) \) is compact open, \( U_1(N) \cap {}^sU_1(N) \supset U_1(N) \cap U(M) \) for some \( (M, N) = 1 \), where \( U(M) = \{ g \in GL_n(\hat{\mathbb{Z}}) : g \equiv 1 \pmod{M} \} \). Since \( \Gamma_1(N) \rightarrow SL_n(\mathbb{Z}/M) \), it follows that
\[
\{ u \in U_1(N) : \det u \equiv 1 \pmod{M} \} \subset \Gamma_1(N)(U_1(N) \cap {}^sU_1(N)).
\]
The desired equality follows by noting that the determinant of the right-hand side is \( \hat{\mathbb{Z}}^\times \), which can be seen by using the theorem on elementary divisors for all \( l|M \).

\( \square \)
The following proposition will be used to obtain cohomology classes from algebraic automorphic representations. It is similar in spirit to [ASS86, §3] for $n = 3$.

**Proposition 10.2.** Suppose that $\pi$ is a cuspidal automorphic representation of $GL_n(\mathbb{A}_\mathbb{Q})$ of conductor $N$. Suppose moreover that for some integers $c_1 > c_2 > \cdots > c_n$,

$\pi_\infty$ corresponds, under the Local Langlands Correspondence, to a representation of $W_\mathbb{R}$ sending $z \in \mathbb{C}^\times$ to

$$\text{diag}(z^{-c_1}z^{-c_n}, z^{-c_n}z^{-c_1}, z^{-c_2}z^{-c_{n-1}}, \ldots) \otimes (z\bar{z})^{(n-1)/2} \in GL_n(\mathbb{C})$$

and $j$ to an element of determinant $(-1)^{\sum c_i + [n/2]}$ (in particular, $\pi$ is regular algebraic; c.f. [Clo90], def. 1.8 and def. 3.12). Let $r$ be the irreducible representation of $GL_n/\mathbb{Q}$ with highest weight $(c_1-(n-1), c_2-(n-2), \ldots, c_n)$. Then there is an $\mathcal{H}_1(N)$-equivariant injection

$$(\pi_\infty)^{U_1(N)} \hookrightarrow H^e(\Gamma_1(N), r)$$

for any $e$ in the range

$$(10.3) \quad \left\lfloor \left(\frac{n}{2}\right)^2 \right\rfloor \leq e < \left\lfloor \left(\frac{n+1}{2}\right)^2 \right\rfloor.$$

**Remark 10.4.**

(i) As $N$ is the conductor of $\pi$, $(\pi_\infty)^{U_1(N)}$ is one-dimensional. Thus we get a Hecke eigenclass in group cohomology.

(ii) It is known that $\Gamma_1(N)$ has virtual cohomological dimension $n(n-1)/2$. In particular, $H^e(\Gamma_1(N), r) = 0$ for $e > n(n-1)/2$ (see [Ser71], p. 192 and the remark on p. 101).

**Proof.** Let $G := GL_n$. For any open compact subgroup $U \subset G(\mathbb{A}^\infty)$, let

$$\tilde{X}_U := G(\mathbb{R})/O(n) \times G(\mathbb{A}^\infty)/U,$$

$$X_U = G(\mathbb{Q}) \backslash \left(G(\mathbb{R})/O(n) \times G(\mathbb{A}^\infty)/U\right),$$

and denote by $\pi_U : \tilde{X}_U \to X_U$ the natural projection. Then $\tilde{X}_U$ and $X_U$ are real manifolds of dimension $\binom{n+1}{2}$ ($X_U$ is not necessarily connected). If $U$ is sufficiently small, $G(\mathbb{Q})$ acts properly discontinuously on $\tilde{X}_U$ and the constant sheaf on $\tilde{X}_U$ with fibre $r$ gives rise to a local system on the quotient $X_U$, which will be denoted by $\mathcal{L}_r$: for any open subset $Z \subset X_U$, $\mathcal{L}_r(Z)$ is the set of locally constant functions

$$(10.5) \quad \{f : \pi_U^{-1}(Z) \to r : f(\gamma x) = \gamma f(x) \quad \forall \gamma \in G(\mathbb{Q}), \quad x \in \pi_U^{-1}(Z)\}.$$

Notice that $r^\vee$ is the representation of $G$ associated to $\pi_\infty$ defined in [Clo90], pp. 112–113 (where it is denoted by $\tau$). By [Clo90, 3.15] there is a $G(\mathbb{A}^\infty)$-equivariant injection

$$\bigoplus_\Pi H^e(\mathfrak{sl}_n, O(n); \Pi_\infty \otimes r) \otimes \Pi_\infty \hookrightarrow \lim_{\nu \to \nu} H^e(X_\nu, \mathcal{L}_r)$$

$$\mathcal{L}_r(Z) \subset \bigoplus_\Pi H^e(\mathfrak{sl}_n, O(n); \Pi_\infty \otimes r) \otimes \Pi_\infty.$$

Here $\Pi_\infty$ is the $SL_n(\mathbb{R})$-cohomology of $\mathfrak{sl}_n$, which is the space of finite-dimensional representations of $SL_n(\mathbb{R})$ that are immediate extensions of irreducible representations (see [Clo90, §3.2] for a discussion of $\Pi_\infty$). The proof of [Clo90, 3.15] relies on the fact that $\pi_\infty$ is a cuspidal automorphic representation, which implies that $\mathcal{L}_r(Z)$ is finite-dimensional for any open subset $Z \subset X_U$. This is a consequence of the Local Langlands Correspondence, which states that $\mathcal{L}_r(Z)$ is isomorphic to the space of functions on the $G(\mathbb{Q})$-equivariant functions on $\tilde{X}_U$ that are invariant under a certain subgroup of $G(\mathbb{Q})$. The details of the proof are omitted here, but they can be found in [Clo90, §3.15].
where \( \Pi \) runs through all cuspidal automorphic representations of \( G(\mathbb{A}_Q) \) whose central character agrees with that of \( r^V \) on \( \mathbb{R}_+^\times \), and where the limit is over all (sufficiently small) compact open subgroups \( V \subset G(\mathbb{A}_\infty) \). The \( G(\mathbb{A}_\infty) \)-action on the right-hand side is as in sublemma 10.6(ii) below. Here \( \mathfrak{sl}_n \) denotes the complexified Lie algebra of \( SL_n(\mathbb{R}) \).

When \( n \) is even, lemma 3.14 in [Clo90] shows that
\[
H^e(\mathfrak{sl}_n, O(n); \pi_\infty \otimes r) \cong \wedge^{e-n^2/4} \mathbb{C}^{n/2-1},
\]
(by the remark on p. 120 in the same reference, there is no quadratic character appearing on the left-hand side).

When \( n \) is odd, the condition on the determinant of \( j \) made above implies that \( \pi_\infty \) is the induction, using a parabolic subgroup of type \((2, 2, \ldots, 2, 1)\), of \( \sigma_1 \otimes \sigma_2 \otimes \cdots \otimes \sigma_{(n-1)/2} \otimes \chi \) (keeping Clozel’s notation), where \( \sigma_i \) is the discrete series representation of central character \(|.|^{-c_i-c_{n+1-i}+n-1} \operatorname{sgn} c_i+c_{n+1-i}+1 \) and lowest weight \( c_i-c_{n+1-i}+1 \), and \( \chi = |.|^{-c_{(n+1)/2}+(n-1)/2} \operatorname{sgn} c_{(n+1)/2} \). This has the consequence that the character considered in [Clo90], p. 120 is even and again we get (without quadratic character on the left-hand side):
\[
H^e(\mathfrak{sl}_n, O(n); \pi_\infty \otimes r) \cong \wedge^{e-(n^2-1)/4} \mathbb{C}^{(n-1)/2}.
\]

Thus we get an \( \mathcal{H}_1(N) \)-equivariant homomorphism
\[
(\pi_\infty) U_1(N) \hookrightarrow \left( \lim_{U} H^e(X_U, \mathcal{L}_r) \right) U_1(N)
\]
for any \( e \) in the range claimed above. It remains to identify the right-hand side as a group cohomology module.

Let \( H^e(X, \mathcal{L}_r) = \lim_V H^e(X_V, \mathcal{L}_r) \) to simplify notations (\( X \) itself will not have any meaning). The following elementary sublemma will be useful.

**Sublemma 10.6.** Suppose that \( U, V \) are sufficiently small compact open subgroups of \( G(\mathbb{A}_\infty) \) and \( e \geq 0 \) arbitrary.

(i) If \( U \subset V \) consider the natural projection map \( f : X_U \to X_V \). Then \( f^* \mathcal{L}_r \cong \mathcal{L}_r \) (canonically) and the induced map \( f^* : H^e(X_V, \mathcal{L}_r) \to H^e(X_U, \mathcal{L}_r) \) is an injection.

(ii) If \( g \in G(\mathbb{A}_\infty) \) and \( U \subset gVg^{-1} \), denote by \([g]\) the natural map \( X_U \to X_V \) given by right multiplication by \( g \). Again there is a canonical isomorphism \([g]^* \mathcal{L}_r \cong \mathcal{L}_r \) and an induced map \([g]^* : H^e(X_V, \mathcal{L}_r) \to H^e(X_U, \mathcal{L}_r) \). It is compatible with the maps defined in (i) and yields a smooth left action of \( G(\mathbb{A}_\infty) \) on the direct limit \( H^e(X, \mathcal{L}_r) \).

(iii) The image of the natural map \( H^e(X_U, \mathcal{L}_r) \to H^e(X, \mathcal{L}_r) \), which is an injection by (i), is precisely the subspace of \( U \)-invariants.

Choose an auxiliary prime \( q \nmid 2N \), and let
\[
U = \{ g \in U_1(N) : g \equiv 1 \pmod{q} \} \subset U_1(N).
\]
The projection of \( U \) to \( G(\mathbb{Q}_q) \) contains no elements of finite order, which implies that \( U \) is sufficiently small in the above sense, so that \( \mathcal{L}_r \) is defined on
$X_U$. (In fact, any other sufficiently small open normal subgroup $U$ of $U_1(N)$ would do.) By the sublemma, $H^e(X, L_r)^{|U_1(N)} = H^e(X_U, L_r)^{|U_1(N)/U}$.

For now, we allow $r$ to be any $\mathbb{C}[G(\mathbb{Q})]$-module. Let $\Gamma := G(\mathbb{Q}) \cap U_1(N)$, an arithmetic subgroup of $G$.

**Claim:** $H^\bullet(X_U, L_r)^{|U_1(N)/U}$ and $H^\bullet(\Gamma, r)$ are universal $\delta$-functors, and they are canonically isomorphic.

First note that if $H \leq K$ are two groups and $V$ is an injective $K$-module (over $\mathbb{C}$, say), then $V|_H$ is an injective $H$-module. The reason is that the left adjoint of the forgetful functor $K\text{-mod} \to H\text{-mod}$ is $\mathbb{C}K \otimes_{\mathbb{C}H} -$, which is exact. By putting $H = \Gamma$, $K = G(\mathbb{Q})$, we see that $H^\bullet(\Gamma, r)$ is a universal $\delta$-functor.

As for $H^\bullet(X_U, L_r)^{|U_1(N)/U}$, note that it is at least a $\delta$-functor: $U_1(N)/U$ is a finite group so that taking $U_1(N)/U$-invariants is an exact functor (we are in characteristic zero!). To demonstrate universality, it suffices to show that $H^e(X_U, L_r) = 0$ if $e > 0$ and $r$ is an injective $\mathbb{C}[G(\mathbb{Q})]$-module. By the strong approximation theorem,

$$G(A) = \prod_{i=1}^t G(\mathbb{Q}) g_i U G(\mathbb{R})$$

for some $g_i \in G(A^\infty)$, which implies that

$$X_U \cong \prod_{i=1}^t (G(\mathbb{Q}) \cap g_i U) \backslash G(\mathbb{R}) / O(n).$$

Under this isomorphism, $L_r$ gives rise to a local system on each space in the disjoint union. It is easy to see that on the $i$-th piece it is the one induced by the constant sheaf on $G(\mathbb{R}) / O(n)$ with fibre $r$ under the $(G(\mathbb{Q}) \cap g_i U)$-action (as in [10.5]). It will be denoted by $L_r$ as well. By [Gro57], corollaire 3 to théorème 5.3.1, $H^e(G(\mathbb{Q}) \cap g_i U) \backslash G(\mathbb{R}) / O(n), L_r) = 0$ if $e > 0$ and $r$ injective as $(G(\mathbb{Q}) \cap g_i U)$-module; in particular if $r$ is injective as $G(\mathbb{Q})$-module. (Note that for the constant sheaf $\mathcal{L}$, $H^i(G(\mathbb{R}) / O(n), \mathcal{L}) = 0$ for $i > 0$ since $G(\mathbb{R}) / O(n)$ is contractible; see [Bre97], thm. III.1.1 for the comparison of sheaf cohomology with singular cohomology).

To check that the two universal $\delta$-functors above are canonically isomorphic, it is enough to identify them in degree 0. By [10.5], $H^0(X_U, L_r)^{|U_1(N)/U}$ is the set of locally constant, $G(\mathbb{Q})$-invariant functions $f : G(A) / U_1(N) O(n) \to r$. By the strong approximation theorem, using that $\det U_1(N) = \mathbb{Z}^\times$, such a function is determined by its values on $G(\mathbb{R})$; by local constancy it is even determined by $f(1) \in r$. It follows easily that the set of possibly values of $f(1)$ is precisely $r^\Gamma = H^0(\Gamma, r)$. This establishes the claim.

**Claim:** The map of $\delta$-functors $H^\bullet(\Gamma, r) \xrightarrow{\text{res}} H^\bullet(\Gamma_1(N), r)$ is a (canonically split) injection.
As \((\Gamma : \Gamma_1(N)) = 2\), this is clear: \(\frac{1}{2}\) cores provides the splitting, where cores is the corestriction map.

**Claim:** The above canonical injection

\[ H^c(X, \mathcal{L}_r)^{U_1(N)} \hookrightarrow H^c(\Gamma_1(N), r) \]

of \(\delta\)-functors is \(\mathcal{H}_1^\delta(N) \cong \mathcal{H}_1(N)\)-equivariant.

Note that the Hecke action on the left is defined in terms of the \(G(\mathbb{A}^\infty)\)-action of sublemma 10.6, whereas the one on the right is the usual one on group cohomology (see §2.1). Both Hecke actions are \(\delta\)-functorial, so again it suffices to check the claim in degree 0. Given \(s \in S_1(N)\), we know by lemma 10.1 that the Hecke operator \(T_s = [\Gamma_1(N)s\Gamma_1(N)] \in \mathcal{H}_1(N)\) corresponds to \(T_s = [U_1(N)sU_1(N)] \in \mathcal{H}_1^\delta(N)\). Moreover, the strong compatibility implies that if \(s_i \in S_1(N)\) \((1 \leq i \leq n)\) are chosen such that

\[
\Gamma_1(N)s\Gamma_1(N) = \prod s_i\Gamma_1(N),
\]

then also

\[
U_1(N)sU_1(N) = \prod s_iU_1(N).
\]

An element of \(H^0(X, \mathcal{L}_r)^{U_1(N)}\) is a locally constant, \(G(\mathbb{Q})\)-invariant function

\[
f : G(\mathbb{A})/U_1(N)O(n) \to r
\]

which is determined by \(f(1) \in r^\Gamma \subset r^{\Gamma_1(N)}\). By the sublemma, \(T_s(f)\) is the function sending \(g \in G(\mathbb{A})\) to \(\sum f(gs_i)\); in particular, the image of 1 is \(\sum f(s_i) = \sum s_if(1) = T_s(f(1))\) (we used that \(f\) is locally constant). This verifies the Hecke equivariance. \(\square\)

Fix an isomorphism \(\iota : \mathbb{C} \to \overline{\mathbb{Q}}_p\).

**Proposition 10.7.** Suppose that \(n = 4\) and that \(p > 2\). Given \(\mu \in X(T)_+\) with \(\mu_1 + \mu_4 = \mu_2 + \mu_3\) and suppose that \(w\) is in the dihedral subgroup \(<(1 2 4 3), (1 2)(3 4)\> \subset S_4 \cong W\) of order 8.

Then there is an irreducible, odd Galois representation \(\rho : G_\mathbb{Q} \to GL_4(\overline{\mathbb{F}}_p)\) with \(\rho|_{I_p} \cong \tau(w, \mu + \rho)\), integers \(N\) prime to \(p\) and \(e \geq 0\), a Serre weight \(F\) occurring as Jordan-Hölder constituent of \(W(\mu)\), and a Hecke eigenclass in

\[ H^c(\Gamma_1(N), F) \]

with attached Galois representation \(\rho\).

Note that the definition \(\tau(w, \mu)\) in (6.16) makes sense even if \((w, \mu)\) is not good.

**Remark 10.8.** This all generalises to \(GL_{2m}\), \(m > 2\), assuming that the automorphic induction needed exists and satisfies the required local compatibility properties. Let us just state the general result and say a few words about the changes in the proof. Here one starts with \(\mu \in X(T)_+\) with \(\mu_1 + \mu_{2m+1-i}\) being independent of \(i\). The tame inertial Galois representations obtained are all \(\tau(w, \mu + \rho)\) where \(w \in S_{2m}\) such that \(w\) respects
the equivalence relation induced by $i \sim 2m + 1 - i$. For generic such $\mu$ in
the lowest alcove one thus obtains $2^m m!/(2m)!$ of all predicted tame inertial
Galois representations in weight $F(\mu)$ \[6.26\].

The only part of the proof that does not immediately generalise is the
construction of appropriate CM fields. The largest possible Galois group for
a totally complex CM fields $K$ of degree $2m$ over $\mathbb{Q}$ is the "hyperoctahedral"

$$\Delta := \left(\mathbb{Z}/2\right)^m \rtimes S_m$$

with $S_m$ acting in the natural way. (It is the largest
since it is isomorphic to the centraliser of an element of cycle type $2^m$ in $S_{2m}$.)
The subgroup of $w \in S_{2m}$ defined in the previous paragraph is the centraliser
of $(1 \, 2 \, 3 \, 4) \cdots (m \, m + 1)$.) For each conjugacy class $C$ of $\Delta$ we need
to be able to choose such a $K = K(C)$ which is unramified at $p$ and with
Frob$_p \in C$. First one finds a totally real number field $K^+$ of degree $m$ over
$\mathbb{Q}$, unramified at $p$, whose Galois group is $S_m$ and with Frob$_p \in C \subset S_m$.
(Use weak approximation on degree $m$ polynomials over $\mathbb{Q}$. In particular one
may force that the Frobenius elements at auxiliary unramified primes are of
all cycle types in their action on the roots. Finally an elementary lemma of
Jordan says that no proper subgroup of a finite group contains an element
of each conjugacy class.) One chooses an auxiliary prime $q$ split in $K^+$
and uses weak approximation to find $\alpha \in (K^+)\times$ such that (i) $\alpha$ is totally
negative, (ii) $\text{ord}_q(\alpha)$ is 0 for all but one prime $q | q$ for which it is 1, (iii) $p$
is unramified in $K = K^+(\sqrt{\alpha})$, and (iv) the set of $p | p$ in $K^+$ that split in
$K$ correspond to the conjugacy class $C$. (By analysing the conjugacy classes
of $\Delta$ one sees that the class of the Frobenius element in $\Delta$ is determined
precisely by its image $C$ in the Galois group of $K^+$—i.e. the information of
how many primes $p | p$ there are in $K^+$ of each residue degree $d$—plus, for
each $d \geq 1$, the number of $p$ of degree $d$ that split in $K$.)

The following lemma will be needed in the proof, whose proof is given on
p. 49. If $K$ is a CM field, we denoted by $K^+$ its totally real subfield, so that
$[K : K^+] \leq 2$.

**Lemma 10.9.** Suppose that $p > 2$.

(i) The Galois group of a quartic, totally complex CM field can be either
of $\mathbb{Z}/2 \times \mathbb{Z}/2$, $\mathbb{Z}/4$ or $D_8$.

(ii) There is a quartic, totally complex CM field $K$ with Galois group
$\Delta \cong D_8$, unramified at $p$ such that Frob$_p \in \Delta$ is (a) trivial, (b)
the complex conjugation, (c) a (non-central) element of order 2 not
fixing $K^+$, (d) a non-central element of order 2 fixing $K^+$, or (e)
an element of order 4.

Note that (ii)(a)–(e) exhaust the conjugacy classes of $\Delta$. The analogous
result is true for the other two kinds of totally complex CM fields and also
if $p = 2$ [Her06] §13].

For both the proof of the proposition and the lemma it will be useful to
keep at hand a diagram of the subgroup lattice of $D_8$, together with explicit
generators of each subgroup.
Proof of prop. [10.7] By lemma [10.9], choose a quartic totally complex CM field $K/\mathbb{Q}$, unramified at $p$, with normal closure $L$ and Galois group $\Delta := \text{Gal}(L/\mathbb{Q})$ dihedral of order 8. The conjugacy class of $\text{Frob}_p$ will be irrelevant until the end of the proof. Let $\mu(K)$ be the torsion subgroup of $\mathcal{O}_K^\times$ and let $w(K)$ be its order; finally let $c \in \Delta$ denote the complex conjugation (the unique central element of order 2).

We now want to make a careful choice of a Hecke character $\chi$ over $K$. For this recall (or notice):

**Sublemma 10.10.** Fix an ideal $\mathfrak{f}\triangleleft \mathcal{O}_K$. There is a bijection between Hecke characters $\chi$ over $K$ of conductor dividing $\mathfrak{f}$ and 3-tuples $(\epsilon, \epsilon_1, \epsilon_\infty)$, where $\epsilon : I^*_K \rightarrow \mathbb{C}^\times$ ($I^*_K$ being the ideals prime to $\mathfrak{f}$), $\epsilon_1 : (\mathcal{O}_K/\mathfrak{f})^\times \rightarrow \mathbb{C}^\times$, and $\epsilon_\infty : K^\times_\infty \rightarrow \mathbb{C}^\times$ continuous such that for all $x \in K^\times$, $x$ prime to $\mathfrak{f}$,

$$(10.11) \quad \epsilon((x)) = \epsilon_1(x)\epsilon_\infty(x).$$

(By weak approximation, $\epsilon_1$ and $\epsilon_\infty$ are in fact determined by $\epsilon$.) The bijection is determined by demanding that

$$\chi(x) = \epsilon_1(x)^{-1}\epsilon_\infty(x^{-1})^{-1}\epsilon((x))$$

for all $x \in \mathbb{A}_K^\times$ that are prime to $\mathfrak{f}$.

Fix for each $\sigma : K \rightarrow \mathbb{C}$ an integer $n_\sigma$ with the property that $n_\sigma + n_\sigma c = w$ for all $\sigma$ (some $w$). These will be pinned down later. Let $\epsilon_\infty : K^\times_\infty \rightarrow \mathbb{C}^\times$ be given by $\epsilon_\infty(x) = |x|^{-3/2} \prod_\sigma \sigma(x)^{n_\sigma}$. (Here, for $x \in \mathbb{R}_K^\times$, $|x|$ is the norm on $\mathbb{R}_K^\times$ and $\sigma(x)$ means $\sigma(x_v)$ for the unique place $v|\infty$ which is induced by $\sigma$ on $K$.)

Claim: $\epsilon_\infty(\mathcal{O}_K^\times)$ is finite, and hence contained in $\mu_{w(L)}(\mathbb{C})$.

Fix an embedding $j : L \rightarrow \mathbb{C}$ and for $\tau \in \Delta$ let $m_\tau = n_\tau j|\mathbb{R}$. In particular, $m_\tau + m_\tau c = w$ for all $\tau$. It will suffice to show that $\prod_\tau \tau(-)^{m_\tau}$ kills $(\mathcal{O}_L^\times)_{\text{tor-free}}$. For, $j \prod_\tau \tau(-)^{m_\tau} = \prod_\sigma \sigma(-)^{n_\sigma[L:K]}$ on $\mathcal{O}_K^\times$.

By the unit theorem, $(\mathcal{O}_L^\times)_{\text{tor-free}} \rightarrow \text{Map}(S_\infty, \mathbb{R})_0$ as $\Delta$-module, where $S_\infty$ is the set of archimedean places of $L$ and the subscript “0” denotes the subspace of $f : S_\infty \rightarrow \mathbb{R}$ with $\sum_v f(v) = 0$. As $\Delta$ acts transitively on $S_\infty$ with stabiliser $\langle c \rangle$, $\text{Map}(S_\infty, \mathbb{R})_0 \cong \mathbb{R}[\Delta/\langle c \rangle]_0$ as $\mathbb{R}\Delta$-module, where the subscript “0” now refers to $\sum_{\Delta/\langle c \rangle} \lambda_g g$ with $\sum_{\Delta/\langle c \rangle} \lambda_g = 0$ (i.e., the augmentation ideal). It will suffice to show that for $\tilde{\nu} \in \Delta/\langle c \rangle$, the action of $\sum_{\Delta} m_\tau \tau(-)$ on $\tilde{\nu} \in \mathbb{R}[\Delta/\langle c \rangle]$ is independent of $\tilde{\nu}$. Indeed,

$$\sum_{\tau \in \Delta} m_\tau \tau\tilde{\nu} = \sum_{\tau \in \Delta/\langle c \rangle} (m_\tau + (w - m_\tau)\tau c)\tilde{\nu} = w \sum_{\tau \in \Delta/\langle c \rangle} \tau\tilde{\nu} = w \sum_{\tau \in \Delta/\langle c \rangle} \tau$$

is independent of $\tilde{\nu}$. This proves the claim.

Note that $L$ does not have any abelian totally complex CM subfields, so the claim implies that $\epsilon_\infty(\mathcal{O}_K^\times) \subset \{\pm 1\}$.
Using the Cebotarev density theorem, choose distinct rational primes \( q_i \) \( i = 1, \ldots, t \) that stay inert in \( K \) (equivalently, \( \text{Frob}_{q_i} \in \Delta \) has order 4). Denote by \( q_i \) the prime of \( K \) lying above \( q_i \).

If \( q_i \in O_K^{\times} \) and \( q_i \equiv 1 \pmod{\prod \mathfrak{q}_i} \) then in particular \( \epsilon_{\infty}(\alpha) \equiv 1 \pmod{q_i} \) (in the subring \( \mathbb{Z} \subset \mathbb{C} \)). But \( \epsilon_{\infty}(\alpha) \in \{ \pm 1 \} \) by above and hence it is 1 (as \( q_1 \) odd). Therefore \( \epsilon_{\infty}|_{O_K^{\times}} \) can be written as

\[
\epsilon_{\infty}|_{O_K^{\times}} : \mathcal{O}_K^{\times} \to (\mathcal{O}_K/\prod \mathfrak{q}_i)^{\times} \xrightarrow{\theta} \mathbb{C}^{\times},
\]

where \( \theta \) is not uniquely determined! Letting \( A \) be the image of \( O_K^{\times} \) in \( (O_K/\prod \mathfrak{q}_i)^{\times} \), we see that \( \theta \) is determined by \( \epsilon_{\infty} \) on \( A \) but nowhere else (the characters of \( (O_K/\prod \mathfrak{q}_i)^{\times}/A \) separate points).

Let \( B_p \) be the \( p \)-Sylow subgroup of \( (O_K/\prod \mathfrak{q}_i)^{\times} \). Observe that

\[
\prod_{i=1}^{t} (((O_K/\mathfrak{q}_i)^{\times})^{q_i^2-1} \not\subset A \cdot B_p.
\]

This is because the size of the 2-torsion on the left-hand side is exactly \( 2^t \geq 8 \), whereas on the right it is bounded above by 4 due to the unit theorem. Therefore we can assume, without loss of generality, that \( \theta \) is non-trivial on \( \prod_{i=1}^{t} (((O_K/\mathfrak{q}_i)^{\times})^{q_i^2-1} \) while being of order prime to \( p \) (simply first extend the given map on \( A \) to \( A \cdot B_p \) by making it trivial on \( B_p \)).

Let \( \mathfrak{f} = \prod \mathfrak{q}_i \) and \( \epsilon_{\mathfrak{f}} = \theta^{-1} \). Writing \( \epsilon_{\mathfrak{f}} = \prod \epsilon_{\mathfrak{q}_i} \) (with the obvious meaning), we see that \( \epsilon_{\mathfrak{q}_i} \) has order not dividing \( q_i^2 - 1 \) for some \( i \). By permuting the \( \mathfrak{q}_i \), let us assume that this happens when \( i = 1 \) and set \( q = q_1, q = q_1 \).

By construction, \( \epsilon_{\mathfrak{f}} \epsilon_{\infty} \) is trivial on \( O_K^{\times} \). Now \( \epsilon \) can be defined by \([AC89, \text{III.6}]\) on the finite index subgroup of \( I_K^{\times} \) generated by \( (x) \) with \( x \in K^{\times} \) prime to \( \mathfrak{f} \) and extended arbitrarily to \( I_K^{\times} \). The above sublemma yields a Hecke character \( \chi \) over \( K \); we record here some of its properties:

\[
\begin{align*}
\bullet \quad & \chi_{\mathfrak{f}}(x) = |x|^{3/2} \prod_\mathfrak{p} \sigma(x)^{-n_\mathfrak{p}}; \\
\bullet \quad & \chi \text{ has conductor dividing } \prod \mathfrak{q}_i \text{ (prime to } p), \\
\bullet \quad & \chi_{|O_K^{\times}} \text{ has order dividing } q^4 - 1 \text{ but not dividing } q^2 - 1, \\
\bullet \quad & \chi(\prod_{\mathfrak{p} \mid \infty} O_K^{\times}) \text{ has order prime to } p.
\end{align*}
\]

By \([AC89, \text{III.6}]\) we can consider the automorphic induction \( \text{AI}_{K/\mathbb{Q}}(\chi) \), which is obtained in two stages: first inducing along the cyclic extension \( K/K^+ : \Pi := \text{AI}_{K/K^+}(\chi) \); then inducing along the cyclic extension \( K^+/\mathbb{Q} : \pi := \text{AI}_{K^+/\mathbb{Q}}(\Pi) \).

Let us write \( \mu + \rho = (a, b, c, d) \), so that \( a > b > c > d \) and \( a + d = b + c \). Suppose that the \( n_\sigma \) above chosen so that \( \{n_\sigma\} = \{a, b, c, d\} \) (note that there are only 8 possible choices as we demanded above that \( n_\sigma + n_{\sigma c} \) is independent of \( \sigma \)).

Claim: \( \pi \) is a cuspidal automorphic representation of \( GL_4(\mathbb{A}_{\mathbb{Q}}) \) of conductor prime to \( p \) to which prop. \([10.2]\) applies with \( (c_1, c_2, c_3, c_4) = (a, b, c, d) \).
Note the following facts about Arthur-Clozel’s cyclic automorphic inductions: (i) they construct them using cyclic base change \([AC89]\), thm. III.6.2), (ii) global cyclic base change is compatible with local base change at all (finite or infinite) places (see \([AC89]\), thm. III.5.1), (iii) local cyclic base change is compatible with restriction under the Local Langlands Correspondence (see \([AC89]\), p. 71 in the archimedean case and \([HT01]\), thm. VII.2.6 in the non-archimedean case).

As \(\chi \neq \chi^c\) (look at either of the infinite components), \(\Pi\) is cuspidal and is determined by

\[
\text{BC}_{K/K^+}(\Pi) \cong \chi \times \chi^c,
\]

where \(\text{BC}_{K/K^+}\) denotes base change from \(K^+\) to \(K\) \((AC89)\), bottom of p. 216). In particular, under the Local Langlands Correspondence the infinite components of \(\Pi\) correspond to the representations sending

\[
z \mapsto |z|^3 \text{diag}(z^{-a}z^{-d}, z^{-d}z^{-a}), \quad \text{resp.}
\]

\[
z \mapsto |z|^3 \text{diag}(z^{-b}z^{-c}, z^{-c}z^{-b}),
\]

for \(z \in W_\mathbb{C} = \mathbb{C}^\times\). Repeating the argument shows that \(\pi\) is cuspidal and that under the Local Langlands Correspondence \(\pi_\infty\) corresponds to a representation sending

\[
z \mapsto |z|^3 \text{diag}(z^{-a}z^{-d}, z^{-d}z^{-a}, z^{-b}z^{-c}, z^{-c}z^{-b}),
\]

for \(z \in W_\mathbb{C}\). As \(a \neq d\) and \(b \neq c\), by the classification of representations of \(W_K\) (see e.g. \([Tat79]\), (2.2.2)), this representation is the direct sum of

\[
z \mapsto |z|^3 \left(\begin{array}{c} z^{-a}z^{-d} \\ z^{-d}z^{-a} \end{array}\right)
\]

\[
j \mapsto \left(\begin{array}{c} (-1)^{a+d} \\ 1 \end{array}\right)
\]

and the same with \((a,d)\) replaced by \((b,c)\). This shows that \((c_1, c_2, c_3, c_4) = (a, b, c, d)\) in the notation of prop. 10.2.

Let \(S\) be the set of primes \(l\) that either ramify in \(K\) or divide a prime where \(\chi\) is ramified. For \(l \not\in S\), \(\pi_l\) is an unramified principal series which corresponds to

\[
\sigma_l := \bigoplus_{\lambda | l} \text{Ind}_{W_\lambda}^{W_\mathbb{A}} \chi_\lambda
\]

under the Local Langlands Correspondence (see \([AC89]\), pp. 214f). In particular, the conductor \(N\) of \(\pi\) is prime to \(p\). This establishes the claim. We get, for any \(e\) as in \((10.3)\), an \(H_1(N)\)-equivariant injection

\[
(\pi_\infty)^{U_1(N)} \hookrightarrow H^e(\Gamma_1(N), r)
\]

with \(r\) of highest weight \(\mu = (a - 3, b - 2, c - 1, d)\).
Let $\Sigma := \text{Ind}_{W_K}^{W_{\mathbb{Q}}} \chi$. Since

$$\Sigma|_{l_0} \cong \bigoplus_{i \mod 4} (\chi|_{l_0})^g,$$

$\Sigma$ is irreducible (this uses (10.12)). The previous paragraph shows that $\Sigma_v$ and $\pi_v$ correspond to each other under the unramified Langlands Correspondence for almost all places $v$. Therefore we can use corollary 4.5 of (10.6) to see that at all finite places $v$, the $L$-factors (and even the $\epsilon$-factors) of $\Sigma_v$ and $\pi_v$ agree. In particular, $\Sigma$ and $\pi$ are ramified at the same set of finite places (namely those finite primes at which the $L$-factor has degree less than 4; for $\pi$ this characterisation follows from (10.3)) It follows that $S$ is precisely the set of prime divisors of $N$.

For $l \mid N$, let $t_l = \{t_{l,1}, \ldots, t_{l,N}\}$ denote the eigenvalues of $\sigma_l(\text{Frob}_l)$. It is known and easy to see that $[G(\mathbb{Z}_l)\left(\begin{array}{ll} 1 & \ldots \\ \vdots & \ddots \end{array}\right) G(\mathbb{Z}_l)]$ with $i$ diagonal entries being equal to $l$ has eigenvalue $s_i(t_l)l^{(4-i)/2}$ on $\pi_l^{G(\mathbb{Z}_l)}$, where $s_i$ denotes the $i$-th elementary symmetric function. Therefore, with the notation of §6.2

$$[U_1(N)\left(\begin{array}{ll} 1 & \ldots \\ \vdots & \ddots \end{array}\right) U_1(N)] = [U_1(N)\left(\begin{array}{ll} 1 & \ldots \\ \vdots & \ddots \end{array}\right) \omega_N(l)U_1(N)]$$

has the same eigenvalue on $(\pi^\infty U_1(N))$. Since this Hecke operator corresponds to $T_{l,i} \in \mathcal{H}_1(N)$ by (10.1), (10.14) yields a Hecke eigenclass in $H^e(\Gamma_1(N), r)$ whose $T_{l,i}$-eigenvalue is $s_i(t_l)l^{(4-i)/2}$ ($\forall l \mid N$, $\forall i$). Equivalently, there is an eigenclass in $H^e(\Gamma_1(N), r \otimes_{\mathbb{Q}} \mathbb{Q}_p)$ with $T_{l,i}$-eigenvalue $\iota(s_i(t_l)l^{(4-i)/2})$ ($\forall l \mid N$, $\forall i$).

**Claim:** There is a Hecke eigenclass in $H^e(\Gamma_1(N), F)$ with $T_{l,i}$-eigenvalue

$$\iota(s_i(t_l)l^{(4-i)/2})$$

($\forall l \mid Np$, $\forall i$) for some Jordan-Hölder constituent $F$ of $W(\mu)$ (as representation of $G(\mathbb{F}_p)$).

By (10.3), II.2.9 and I.10.4, $r$ has a model $M$ over $\mathbb{Z}_{(p)}$ (a representation of the reductive group scheme $GL_{n/\mathbb{Z}_{(p)}}$). Let $\overline{M}$ denote its reduction mod $p$, a representation of $GL_{n/\mathbb{F}_p}$. By (10.3) I.2.11(10), $M$ has a formal character compatible with that of $r$ and $\overline{M}$.

By (10.3), §2.4, thm. 4, $\Gamma_1(N)$ is of type (WFL). In particular, the $\Gamma_1(N)$-module $\mathbb{Z}$ has a resolution with finite free $\Gamma_1(N)$-modules and, a fortiori, for any noetherian ring $A$, $H^e(\Gamma_1(N), P)$ is a finite $A$-module whenever $P$ is a finite $A$-module with commuting $\Gamma_1(N)$-action, and $H^e(\Gamma_1(N), -)$ commutes with flat base extension (see (10.3), remark on p. 101).

Consider now only the Hecke operators $T_{l,i}$ with $l \mid Np$. For any $\mathbb{Z}_{(p)}$-algebra $R$, let $r_R := M \otimes_{\mathbb{Z}_{(p)}} R$. Note that $r^\infty_R$ is a $GL_n(\mathbb{Z}_{(p)})$-invariant
\( \mathbb{Z}_p \)-lattice in \( r_{\mathbb{F}_p} \cong r \otimes_{\mathbb{Q}_l} \mathbb{Q}_p \). Since
\[
H^c(\Gamma_1(N), r_{\mathbb{Q}_p}) \cong H^c(\Gamma_1(N), r_{\mathbb{Q}_p}) \otimes_{\mathbb{Q}_p} \mathbb{Q}_p
\]
(Hecke equivariantly) and this space is finite-dimensional over \( \mathbb{Q}_p \), the simultaneous generalised eigenspaces for \( T_{l,i} \) with \( l \mid Np \) can be defined over some finite extension \( E/\mathbb{Q}_p \). Thus the above set of Hecke eigenvalues also occurs in \( H^c(\Gamma_1(N), r_E) \). Consider the following Hecke equivariant map:
\[
H^c(\Gamma_1(N), r_{\mathcal{O}_E}) \otimes_{\mathcal{O}_E} k_E \rightarrow H^c(\Gamma_1(N), r_E).
\]
The image of the map is a lattice in \( H^c(\Gamma_1(N), r_E) \); this follows by looking at the long exact sequence associated to \( 0 \rightarrow r_{\mathcal{O}_E} \rightarrow r_E \rightarrow r_E/r_{\mathcal{O}_E} \rightarrow 0 \). By scaling the Hecke eigenclass in \( H^c(\Gamma_1(N), r_E) \), we may assume it lies in this sublattice and has non-zero reduction in \( H^c(\Gamma_1(N), r_{\mathcal{O}_E}) \otimes_{\mathcal{O}_E} k_E \).

**Sublemma 10.15.** Suppose that \( \kappa \) is an algebraically closed field and that \( \mathcal{H} \) is a commutative \( \kappa \)-algebra. If \( 0 \rightarrow V' \rightarrow V \rightarrow V'' \rightarrow 0 \) is a short exact sequence of \( \mathcal{H} \)-modules which are finite-dimensional over \( \kappa \), then a system of Hecke eigenvalues \( \mathcal{H} \rightarrow \kappa \) occurs in \( V \) if and only if it occurs in one of \( V' \) or \( V'' \).

The only non-obvious part is to lift from \( V'' \) to \( V \). One decomposes \( V \) and \( V'' \) as direct sums of simultaneous generalised eigenspaces for all \( T \in \mathcal{H} \), each of which contains a simultaneous eigenvector.

We can apply it to the Hecke equivariant map
\[
H^c(\Gamma_1(N), r_{\mathcal{O}_E}) \otimes_{\mathcal{O}_E} k_E \rightarrow H^c(\Gamma_1(N), r_{\mathcal{O}_E}) \otimes_{\mathcal{O}_E} k_E
\]
and thus, by enlarging \( E \) if necessary, lift the system of Hecke eigenvalues considered above to \( H^c(\Gamma_1(N), r_{\mathcal{O}_E}) \otimes_{\mathcal{O}_E} k_E \).

Finally, the long exact sequence associated to \( 0 \rightarrow r_{\mathcal{O}_E} \rightarrow r_{\mathcal{O}_E} \rightarrow r_{k_E} \rightarrow 0 \) yields a Hecke equivariant injection
\[
H^c(\Gamma_1(N), r_{\mathcal{O}_E}) \otimes_{\mathcal{O}_E} k_E \hookrightarrow H^c(\Gamma_1(N), r_{k_E}) \hookrightarrow H^c(\Gamma_1(N), r_{\mathcal{F}_p}).
\]

Thus there is a Hecke eigenclass in \( H^c(\Gamma_1(N), r_{\mathcal{F}_p}) \) with \( T_{l,i} \)-eigenvalue
\[
\iota(s_i(t_j) : l^{(4-i)/2}) \quad (\forall l \mid N, \forall i).
\]

Note that the \( G \)-modules \( r_{\mathcal{F}_p} = \mathcal{M} \otimes_{\mathbb{F}_p} \mathbb{F}_p \) and \( W(\mu) \) have the same formal character: \( \overline{M} \) and \( r \) have compatible formal characters as discussed above, and the formal characters of both \( r \) and \( W(\mu) \) are given by the Weyl character formula for the highest weight \( \mu \) [Jan03, II.5.10]. Now by [Jan03], II.2.7 and II.5.8, \( r_{\mathcal{F}_p} \) and \( W(\mu) \) have isomorphic semisimplifications (as \( G \)-modules, and hence as \( G(\mathbb{F}_p) \)-modules). By the sublemma, the same system of Hecke eigenvalues obtained in \( H^c(\Gamma_1(N), r_{\mathcal{F}_p}) \) also occurs in \( H^c(\Gamma_1(N), F) \) for some Jordan-Hölder constituent \( F \) of \( W(\mu) \). This establishes the claim.

The Hecke character \( \eta := \chi^{-1}|x|^{3/2} \) is algebraic with algebraic infinity type \( \eta_{\infty}(x) = \prod \sigma(x)^{\alpha} \). Recall the definition of the associated \( p \)-adic Galois
character \(\eta(p)\) (using the global Artin map; see e.g. \[HT01\], pp. 20f):

\[
\eta(p) : G_{K}^{ab} \cong K \times K_{\infty,+} \backslash \mathbb{A}_{K}^{\times} \to \overline{\mathbb{Q}}_{p}^{\times}
\]

\[
x \mapsto \nu(x^{\infty}) \prod_{\tau : K \to \overline{\mathbb{Q}}_{p}} \tau(x_{p})^{n_{\tau} - 1(r)}.
\]

(10.16)

Here, the convention is that \(\tau(x_{p})\) means \(\tau(x_{\nu})\) for the unique \(\nu\mid p\) induced by \(\tau\) on \(K\). In particular, \(\eta(p)|_{G_{K_{\lambda}}} = \iota(\chi^{-1}_{\lambda}| \lambda^{-3/2})\) under the local Artin map for all \(\lambda \nmid p\).

Claim: The Galois representation

\[
\rho := \text{Ind}_{G_{K}}^{G_{Q}} (\eta(p))
\]

is attached to the eigenclass in \(H^{e}(\Gamma_{1}(N), F)\) constructed above. It is continuous, irreducible, odd and its ramification outside \(p\) occurs precisely at all \(l|N\).

Clearly, \(\rho\) is continuous. By Mackey’s formula, using the local Artin map, for any prime \(l \neq p\),

\[
\rho|_{I_{l}} \cong \bigoplus_{\lambda | l} \bigoplus_{g \in G_{l}\backslash G_{l}} \text{Ind}_{I_{l}}^{G_{l}} (\overline{\chi}_{\lambda}^{-1}|_{I_{l}}^{g}).
\]

By Frobenius reciprocity, \(I_{l}\) acts trivially on the direct summand corresponding to the index \((\lambda, g)\) if and only if \(I_{\lambda} = I_{l}\) and \(\overline{\chi}|_{I_{\lambda}} = 1\). Thus the claim about ramification outside \(p\) follows from (10.12) and the fact that \(S\) is the set of primes dividing \(N\). Specialising now to \(l = q\) we even get:

\[
\rho|_{I_{q}} \cong \bigoplus_{i \equiv 4} (\overline{\chi}_{q}|_{I_{q}})^{-q^{i}}.
\]

Note that even the order of \(\overline{\chi}_{q}|_{I_{q}}\) does not divide \(q^{2} - 1\), by (10.12). Hence \(\rho|_{G_{q}}\) is irreducible; a fortiori, so is \(\rho\).

For \(l \nmid Np\), we know that

\[
\rho|_{G_{l}} \cong \bigoplus_{\lambda | l} \text{Ind}_{G_{\lambda}}^{G_{l}} (\eta(p)|_{G_{\lambda}})
\]

is unramified. Using an explicit basis, we see that \(\rho(\text{Frob}_{l})\) has characteristic polynomial

\[
X^{[K_{\lambda}:Q_{l}]} - \eta(p)(\text{Frob}_{\lambda})
\]

on the \(\lambda\)-direct summand. A similar consideration applied to \(\sigma_{l}\) in (10.13) shows that the eigenvalues of \(\rho(\text{Frob}_{l})\) are \(\iota(t_{l,j}^{-1}|_{l^{-3/2}})\) (recall that the \(t_{l,j}\) are the eigenvalues of \(\sigma_{l}(\text{Frob})\) and that \(\eta(p)|_{G_{\lambda}} = \iota(\chi_{\lambda}^{-1}| \lambda^{-3/2})\)).

By the following simple computation, and the fact that \(S\) is the set of prime divisors of \(N\), we see that \(\rho\) is attached to the eigenclass constructed.
above: for all \( l \nmid N p, \)
\[
\sum_{j=0}^{4} (-1)^j l^{i(1-1)/2} s_i(t_l l) \cdot l^{i(4-i)/2} X^i = \prod_{j=1}^{4} (1 - l(t_l l^{3/2}) \cdot X).
\]

Finally, note that
\[
\rho \mid_{G_{R}} \cong \left( \text{Ind}_{G_{C}}^{G_{R}}(1) \right) \oplus 2,
\]
which has eigenvalues 1 and -1 twice each on complex conjugation. Thus \( \rho \) is odd and the claim is established.

To determine \( \rho \mid_{I_{p}} \), note that
\[
\rho \mid_{I_{p}} \cong \bigoplus_{p \mid p} \bigoplus_{\text{mod } f_{p}} \eta(p)^{1} \mid_{I_{p}}
\]
where \( f_{p} \) is the inertial degree. Also, as \( \chi \) is unramified at all \( p \mid p \) we get from (10.16),
\[
\eta(p) : x_{p} \mapsto \prod_{\tau : K \rightarrow \overline{Q}_{p}} \tau(x_{p})^{n_{1} - 1(\tau)}
\]
for \( x_{p} \in \prod_{p \mid p} \mathcal{O}_{K_{p}}^{\times} \). Fix for each \( p \mid p \) an embedding \( \tau_{p} : K \rightarrow \overline{Q}_{p} \) which induces the place \( p \) on \( K \) and denote by \( \phi : \overline{Q}_{p}^{nr} \rightarrow \overline{Q}_{p}^{nr} \) the arithmetic Frobenius. Recall that the composite \( I_{K_{p}} \rightarrow \mathcal{O}_{K_{p}}^{\times} \rightarrow k_{p}^{\times} \), where the first map is induced by local class field theory and the second is \( x_{p} \mapsto \overline{x}_{p} \), is the fundamental tame character \( \theta_{p} \) of level \( f_{p} \) (see [Ser72], prop. 3 with \( L = K_{d} \) in Serre’s notation; notice the different sign convention for the local Artin map). We get
\[
\eta(p) : x_{p} \mapsto \tau_{p}^{\sum_{\text{mod } f_{p}} \phi^{n_{1} - 1(\phi^{\sigma})}}
\]
for \( x_{p} \in \mathcal{O}_{K_{p}}^{\times} \).

Now we let the \( n_{\sigma} \) vary through the 8 allowed permutations of \( \{a, b, c, d\} \) (recall that \( n_{\sigma} + n_{\sigma^c} \) has to be independent of \( \sigma \)). To see which \( \rho \mid_{I_{p}} \) are obtained for a fixed conjugacy class of \( \text{Frob}_{p} \in \Delta \), it thus only matters how complex conjugation acts on the set of \( p \mid p \), and what \( f_{p} \) is in each case. With the notation of lemma [10.9]iv we obtain \( \tau(w, \mu + \rho) \) where \( w \) can equal 1 in case (a), \( (1 4)(2 3) \) in case (b), either of \( (1 2)(3 4), (1 3)(2 4) \) in case (c), either of \( (1 4), (2 3) \) in case (d), and either of \( (1 2 4 3), (1 3 4 2) \) in case (e). This completes the proof.

Suppose that \( F \cong F(\mu) \) is a regular Serre weight and that \( \tau : I_{p} \rightarrow GL_{n}(\mathbb{F}_{p}) \) is tame and can be extended to \( G_{p} \). Suppose that \( F \in W^{\vee}(\tau) \).

**Definition 10.17.**

(i) We say that an irreducible, odd Galois representation \( \rho : G_{Q} \rightarrow GL_{n}(\mathbb{F}_{p}) \) provides evidence for \((F, \tau)\) if \( \rho \mid_{I_{p}} \cong \tau \) and \( F \in W(\rho) \).
(ii) Suppose that none of the Serre weights in \(JH(W(\mu))\) lie on an alcove boundary \([3.11]\); in particular they are all regular. We say that an irreducible, odd Galois representation \(\rho : G_Q \to GL_n(\overline{\mathbb{F}_p})\) provides weak evidence for \((F,\tau)\) if \(\rho|_{I_p} \cong \tau\), \(W(\rho) \cap JH(W(\mu)) \neq \emptyset\), and \(W^J(\tau) \cap JH(W(\mu)) = \{F\}\).

By \(JH(W(\mu))\) in (ii) we mean the Jordan-Hölder constituents of \(W(\mu)\) as \(GL_n(\overline{\mathbb{F}_p})\)-representation. Let us denote by \(C\) the alcove containing \(\mu\). At least for \(\mu\) sufficiently deep in \(C\) it is clear that all constituents of \(W(\mu)\) besides \(F\) lie in alcoves strictly below \(C\), Thus if the conjecture correctly predicts the weights of \(\tau\) in all alcoves strictly below \(C\), \(\rho\) provides actual evidence for \((F,\tau)\).

**Theorem 10.18.** Suppose that \(F \cong F(\mu)\) with \(\mu_1 + \mu_4 = \mu_2 + \mu_3\) lies sufficiently deep in one of the four possible restricted alcoves.

If \(F \in C_0\), and for 8 of the 24 tame inertial representations \(\tau\) with \(F \in W^J(\tau)\), prop. \([10.7]\) provides evidence for \((F,\tau)\).

If \(F \in C_1\) (resp., \(C_4\), \(C_5\)), and for 8 of the 48 (resp., 120, 192) tame inertial representations \(\tau\) with \(F \in W^J(\tau)\), prop. \([10.7]\) provides weak evidence for \((F,\tau)\).

**Proof.** Note that the Galois representations \(\rho\) obtained from prop. \([10.7]\) satisfy \(F \in W^J(\rho|_{I_p})\) by \([6.26]\). Also, by \([6.26]\) and \([6.29]\) the set \(\{\tau : F \in W^J(\tau)\}\) has cardinality \(\#W \cdot \{C' : C'\text{ dominant}, C' \uparrow C\}\), where \(C\) is the alcove containing \(\mu\).

It remains to verify that \(W^J(\tau) \cap JH(\lambda) = \{F\}\) for all 8 of the values \(\tau\in W\) as in prop. \([10.7]\). Suppose thus that \(F' \in W^J(\tau) \cap JH(\lambda)\). Then there exists a constituent \(F(\lambda)\) of \(W(\mu)\) as \(G\)-module \((\lambda \in X(T)_+)\) such that \(F' \in JH(F(\lambda))\). From the proof of prop. \([9.11]\) in particular from \([9.2]\), \([9.3]\), it follows that there exist \(\mu' \in X(T)_+\) and \(\tau' \in W\) such that \(\mu' \uparrow \lambda \uparrow \mu\) and \(\tau' \cong \tau(\mu', \mu' + \rho)\). But \([6.29]\) implies that \(\mu' = \lambda = \mu\), so that \(F' \cong F(\lambda) \cong F(\mu) \cong F\), as required. \(\Box\)

**Proof of lemma \([10.7]\).** (i) The Galois group is a transitive permutation group on four letters which has a central element of order 2 (as \(L\) is CM). The result follows by considering the centralisers of a 2-cycle (it is the Klein 4-group) and of a permutation of cycle type \((2, 2)\) (it is dihedral of order 8).

(ii) It would be possible to give a proof which works more generally, as alluded to in \([10.8]\). We give a more direct argument instead.

Consider \(K = \mathbb{Q}(\sqrt{a + b\sqrt{d}})\) with integers \(a, b, d\), with normal closure (over \(\mathbb{Q}\)) denoted by \(L\). If \(d > 0\) and \(a^2 - b^2d > 0\) lie in different, non-trivial square classes of \(\mathbb{Q}\times\) and \(a < 0\) then \(K\) is a quartic CM field with dihedral Galois group of order 8. For, \(K\) is a totally complex quadratic extension of \(\mathbb{Q}(\sqrt{d})\), a totally real quadratic field. Moreover, \(K/\mathbb{Q}\) is not Galois, as it would otherwise contain a square root of \((a + b\sqrt{d})(a - b\sqrt{d}) = a^2 - b^2d > 0\), which is ruled out by the assumptions.
Note that cases (c) and (d) are equivalent upon replacing \( K \) by one of the two quartic, totally complex subfields \( K' \subset L \) that are not conjugate to \( K \). Let us henceforth assume that we are not in case (c).

In addition to requiring \( a < 0 \), \( a^2 - b^2d > 0 \) and \( d > 1 \) with \( d \) square-free, we also demand that \( b > 0 \), \( a < -(b^2d + 1)/2 \) and that:

- \( a \equiv d \equiv 1, b \equiv 0 \pmod{p} \) and \( d \nmid a \) in case (a),
- \( \left( \frac{a}{p} \right) = -1, d \equiv 1, b \equiv 0 \pmod{p} \) and \( d \nmid a \) in case (b),
- \( \left( \frac{2a-1}{p} \right) = -1, d \equiv 1, b \equiv a - 1 \pmod{p} \) in case (d),
- \( \left( \frac{d}{p} \right) \equiv \left( \frac{a^2-b^2d}{p} \right) = -1 \) and \( d \nmid a \) in case (e).

(Choose \( d \) first and \( a \) last.) In the fourth case, choose \( d \) with \( \left( \frac{a}{p} \right) = -1 \), \( \left( \frac{d}{p} \right) = 1 \). Then \( a \equiv d, b \equiv 1 \pmod{p} \) will work.

Clearly the conditions ensure that \( a^2 - b^2d \) and \( d \) lie in different, non-trivial square classes. The corresponding CM field \( K \) is unramified at \( p \), as \( d \) and \( a^2 - b^2d \) are prime to \( p \). In the first two cases, \( L^+ \) is split at \( p \), as \( \left( \frac{d}{p} \right) = \left( \frac{a^2-b^2d}{p} \right) = 1 \). Moreover \( \mathbb{Q}_p(\sqrt{a + b\sqrt{d}}) = \mathbb{Q}_p \) in the first, but not the second, case as the reduction mod \( p \) of \( a + b\sqrt{d} \) is a square, resp. a non-square, in \( \mathbb{F}_p^\times \). Thus \( K \) is as required in the first two cases. In the third case, \( K^+ \) is split at \( p \) whereas the other two quadratic subfields of \( L \) are inert at \( p \), establishing that \( K \) is as in (d). The fourth case is similar with \( F := \mathbb{Q}(\sqrt{d(a^2 - b^2d)}) \) split at \( p \) and the other two quadratic subfields of \( L \) inert at \( p \), once we see that \( F \) is indeed the subfield of \( L \) fixed by the elements of order 4 in \( \Delta \). As \( L = \mathbb{Q}(\alpha, \alpha') \) with \( \alpha = \sqrt{a + b\sqrt{d}}, \alpha' = \sqrt{a - b\sqrt{d}} \), any element of \( \Delta \) is determined by its action on \( \alpha \) and \( \alpha' \). The conjugates of \( \alpha \) are \( S = \{ \pm \alpha, \pm \alpha' \} \). Given \( s_1, s_2 \in S, s_1 \neq s_2 \) there is a \( \tau \in \Delta \) such that \( \tau(\alpha) = s_1 \) and \( \tau(\alpha') = s_2 \) (as \( \#\Delta = 8 \)). Thus an element of order 4 in \( \Delta \) is given by \( \tau \) with \( \tau(\alpha) = \alpha', \tau(\alpha') = -\alpha \). In particular, \( \tau(\sqrt{d}) = -\sqrt{d} \) and hence \( \tau \) fixes \( \alpha \alpha' \sqrt{d} \), as required.

\[ \square \]

11. Weights in Serre’s Conjecture for Hilbert modular forms

In [BDJ], Buzzard, Diamond and Jarvis formulate a Serre-type conjecture for Hilbert modular forms. Theorem 11.3 below will show that their weight conjecture in the tame case is related, via an operation on the Serre weights analogous to \( \mathcal{R} \) in [63.3] to the decompositions of irreducible representations of \( GL_2(\mathbb{F}) \) over \( \overline{\mathbb{Q}}_p \) when reduced mod \( p \) (where \( \mathbb{F} \) is a finite field of characteristic \( p \)). They work with a totally real number field \( K \) that is unramified at \( p \).

Suppose that \( \rho : G_K \rightarrow GL_2(\mathbb{F}_p) \) is an irreducible, totally odd representation. A Serre weight in this context is an isomorphism class of irreducible representations of \( GL_2(\mathcal{O}_K/p) \cong \prod_{p \mid \mathfrak{f}} GL_2(k_p) \) over \( \overline{\mathbb{F}}_p \) where \( k_p \) is the residue field of \( K \) at \( p \). Any such representation is isomorphic to \( \bigotimes_{p \mid \mathfrak{f}} W_p \) with \( W_p \) an irreducible representation of \( GL_2(k_p) \). The weight conjecture
in [BDJ] defines the $W_p$ independently of one another in terms of $\rho|_{I_p}$. Let us therefore restrict our attention to a single prime $p$. Fix an embedding $K \rightarrow \mathbb{Q}_p$ inducing the place $p$ on $K$. Let $I_p := \text{Gal}(\mathbb{Q}_p/K_{n-r})$ denote the corresponding inertia subgroup. Let $k'_p \subset \mathbb{F}_p$ be the quadratic extension of $k_p$. Let $f := [k_p : \mathbb{F}_p]$. There are canonical fundamental tame characters $\psi : I_p \rightarrow k'_p$ of level 2 and $\psi' : I_p \rightarrow (k'_p)^\times$ of level $2f$.

For $i \in \mathbb{Z}/f$, let $\lambda_i$ be the $p^i$-th power of $k'_p \rightarrow \mathbb{F}_p^\times$ and for $i \in \mathbb{Z}/2f$ let $\lambda_{i'}$ be the $p^{i'}$-th power of $(k'_p)^\times \rightarrow \mathbb{F}_p^\times$. Also let $\psi_i := \lambda_i \circ \psi$ for $i \in \mathbb{Z}/f$ and $\psi_{i'} := \lambda_{i'} \circ \psi'$ for $i \in \mathbb{Z}/2f$.

To describe the set $W_{\text{Ser},p}$ of isomorphism classes of irreducible representations of $GL_2(k_p)$ over $\overline{\mathbb{F}}_p$ (Serre weights at $p$), note first that theorem 3.10 shows that

$$W_{\text{Ser},p} = \{F(a, b) : 0 \leq a - b \leq p^f - 1, 0 \leq b < p^f - 1\}.$$  

If we write $a - b = \sum_{i=0}^{f-1} m_i p^i$, $b = \sum_{i=0}^{f-1} b_i p^i$ with $0 \leq m_i$, $b_i \leq p - 1$ then by the Steinberg tensor product theorem (3.9),

$$F(a, b) \cong \bigotimes_{i=0}^{f-1} F(b_i + m_i, b_i)(p^i).$$

Since $F(b_i + m_i, b_i) \cong \text{Sym}^{m_i} \mathbb{F}_p^2 \otimes \det^{b_i}$ (see (3.3),

$$F(a, b) \cong \bigotimes_{i=0}^{f-1} (\text{Sym}^{m_i} k_p^2 \otimes \det^{b_i}) \otimes k_p, \phi^i \mathbb{F}_p$$

where $\phi : k_p \rightarrow k_p$ is the $p$-power Frobenius element. This representation will also be denoted by $F_{\mathfrak{m}, \mathfrak{b}}$.

Suppose that $p$ is tame at $p$. Then we can write $\rho|_{I_p} \cong \chi_1 \oplus \chi_2$. We say that $\rho|_{I_p}$ is of niveau 1 if $\chi_i^{p^f-1} = 1$ ($i = 1, 2$) and of niveau 2 otherwise. Let us recall the definition of the conjectured set of weights $W_p^2(\rho)$ from [BDJ] in the tame case. If $\rho|_{I_p}$ is of niveau 1, $W_p^2(\rho)$ consists of all $F_{\mathfrak{m}, \mathfrak{b}}$ such that

$$\rho|_{I_p} \sim \left(\prod_J \psi_i^{m_i+1} \prod_{J'} \psi_i^{m_i+1}\right) \prod_i \psi_i^{b_i}$$

for some $J \subset \mathbb{Z}/f$. If $\rho|_{I_p}$ is of niveau 2, $W_p^2(\rho)$ consists of all $F_{\mathfrak{m}, \mathfrak{b}}$ such that

$$\rho|_{I_p} \sim \left(\prod_J \psi_i^{m_i+1} \prod_{J'} \psi_i^{m_i+1}\right) \prod_i \psi_i^{b_i}$$

for some $J \subset \mathbb{Z}/2f$ projecting bijectively onto $\mathbb{Z}/f$ (under the natural map). Here we are abusing notation in that the indices of $m$ and $b$ should be taken “mod $f$”.

Associated to each $\rho|_{I_p}$ define a representation $V_p(\rho|_{I_p})$ of $GL_2(k_p)$ over $\mathbb{Q}_p$. The Teichmüller lift will again be denoted by $\sim$. For characters $\chi_i :
Suppose that \( \chi : (k_p^\times)^n \to \overline{Q}_p^\times \) which does not factor through the norm \( (k_p^\times)^n \to k_p^\times \), the cuspidal representation \( \kappa(\chi) \) of \( GL_2(k_p) \) was defined in [46, 7.3].

**Definition 11.2.**

(i) If \( \rho|_{I_p} \sim \left( \prod \psi_i^{c_i} \right) \left( \prod \psi'_i \right) \) is of niveau 1,

\[
V_p(\rho|_{I_p}) := I(\prod \tilde{\lambda}_i, \prod \tilde{\lambda}'_i).
\]

(ii) If \( \rho|_{I_p} \sim \left( \prod \psi_i^{\gamma_i} \right) \left( \prod \psi'_i \right) \) is of niveau 2,

\[
V_p(\rho|_{I_p}) := \kappa(\prod \tilde{\lambda}'_i).
\]

Note that in (ii), \( i \) runs through \( \mathbb{Z}/2f \). In particular, \( V_p(\rho|_{I_p} \otimes (\chi \circ \psi)) \cong V_p(\rho|_{I_p}) \otimes \tilde{\chi} \) for any character \( \chi : k_p^\times \to \overline{F}_p^\times \). Also note that this is the same as \( V(\rho|_{I_p}) \) in (6.19) in light of (12). We prefer to use the above description here as we can then use the decomposition formulae derived in [Dia]. (To identify his \( \Theta(\chi) \) with \( \kappa(\chi) \), compare their characters at elements whose characteristic polynomial is irreducible using [DL76, 7.3].)

A regular Serre weight at \( p \) is any Serre weight \( F_{m,b} \) with \( 0 \leq m_i < p - 1 \) for all \( i \). The set of regular Serre weights at \( p \) is denoted by \( W_{\text{reg},p} \). Define \( \mathcal{R}_p : W_{\text{reg},p} \to W_{\text{reg},p} \) by

\[
\mathcal{R}_p(F(a,b)) = F(b + (p - 2)\sum_{i=0}^{f-1} p^i, a),
\]

(compare this with \( \mathcal{R} \) in (6.3).

**Theorem 11.3.** Suppose that \( \rho : G_K \to GL_2(\overline{F}_p) \) is irreducible, totally odd, and tame at \( p \).

(i) \( W_{\text{reg},p}(\rho) \cap W_{\text{reg},p} = \mathcal{R}_p(JH(V_p(\rho|_{I_p}))) \cap W_{\text{reg},p} \).

(ii) There is a multi-valued function \( \mathcal{R}_{\text{ext},p} : W_{\text{Ser},p} \to W_{\text{Ser},p} \) that extends \( \mathcal{R}_p \) such that

\[
W_{\text{reg},p}(\rho) = \mathcal{R}_{\text{ext},p}(JH(V_p(\rho|_{I_p}))).
\]

The following definition of \( \mathcal{R}_{\text{ext},p} \) will be shown to satisfy part (ii) of the theorem. Suppose that \( F \cong F(a,b) \) with \( 0 \leq a - b \leq p^f - 1 \). We can write \( a - b = \sum_{i=0}^{f-1} m_i p^i \) for some \( 0 \leq m_i \leq p - 1 \). Define a collection \( \mathcal{S}(F) \) of subsets of \( \mathbb{Z}/f \) by: \( S \in \mathcal{S}(F) \) if and only if for all \( s \in S \), \( m_s \neq 0 \) and there is an \( i \) such that \( m_i = p - 1 \), \( m_{i+1} = \cdots = m_{s-1} = p - 2 \) and \( \{i, i + 1, \ldots, s - 1\} \cap S = \emptyset \). Then \( \mathcal{R}_{\text{ext},p}(F) \) is defined to be

\[
\left\{ F(a',b') : \exists S \in \mathcal{S}(F), \ a' \equiv b - \sum_{i \in S} p^i, \ b' \equiv a - \sum_{i \in S} p^i \pmod{p^f - 1} \right\}.
\]
In particular, for this choice of $\mathcal{R}_{\text{ext},p}$, if $F$ is a regular Serre weight then $S(F) = \{\emptyset\}$, so $\mathcal{R}_{p}(F) = \mathcal{R}_{\text{ext},p}(F)$ unless $F$ is a twist of $F((p - 2)\sum p^{i}, 0)$ in which case $\mathcal{R}_{\text{ext},p}(F)$ contains one more weight.

The proof will require several lemmas, proved below.

**Lemma 11.4.** Suppose that $0 \leq m_{i} \leq p - 1$ ($i \in \mathbb{Z}/f$).

(i) Suppose that $\rho|_{I_{p}}$ is of niveau 1. Then $F_{\vec{m},\vec{b}}$ is a constituent of $V_{p}(\rho|_{I_{p}})$ if and only if

$$\rho|_{I_{p}} \sim \left( \prod_{J \subset \mathbb{Z}/f} \psi^{p - 1 - m_{i}}_{i} \right) \prod_{J} \psi^{m_{i} + b_{i}}$$

for some $J \subset \mathbb{Z}/f$.

(ii) Suppose that $\rho|_{I_{p}}$ is of niveau 2. Then $F_{\vec{m},\vec{b}}$ is a constituent of $V_{p}(\rho|_{I_{p}})$ if and only if

$$\rho|_{I_{p}} \sim \left( \prod_{J \subset \mathbb{Z}/f} \psi^{p - 1 - m_{i}}_{i} \right) \prod_{J} \psi^{m_{i} + b_{i}}$$

for some $J \subset \mathbb{Z}/2f$ projecting bijectively onto $\mathbb{Z}/f$.

Let me explain the idea of the proof of the theorem. The above lemma is the key tool that lets us relate the conjectured weight set $W^{?}_{p}(\rho)$ with the decomposition of $V_{p}(\rho|_{I_{p}})$. This works perfectly for regular Serre weights. In general the problem is that the number of constituents of $V_{p}(\rho|_{I_{p}})$ might be a lot smaller than $\#W^{?}_{p}(\rho)$. This suggests looking for a multi-valued function extending $\mathcal{R}$. In view of lemma 11.4 we have to find rules to convert an expression of the form

$$\rho|_{I_{p}} \sim \left( \prod_{J \subset \mathbb{Z}/f} \psi^{\alpha(i)}_{i} \right) \prod_{J} \psi^{\alpha(i)}$$

for some $J \subset \mathbb{Z}/f$, $0 \leq \alpha(i) \leq p - 1$ and some character $\chi$ into an expression of the form

$$\rho|_{I_{p}} \sim \left( \prod_{L \subset \mathbb{Z}/f} \psi^{\beta(i)}_{i} \right) \prod_{L} \psi^{\beta(i)}$$

for some $L \subset \mathbb{Z}/f$, $1 \leq \beta(i) \leq p$ and some character $\chi'$ in such a way that the map

$$(\alpha, \chi) \mapsto (\beta, \chi')$$

does not depend on $J$ and works equally well for the analogous expressions of niveau 2. The theorem shows, roughly speaking, that there are enough such rules to explain all of $W^{?}_{p}(\rho)$.

To make this principle concrete, consider $f = 3$ and $\vec{\alpha} = (0, 1, p - 1)$ and $\chi = 1$. It is very instructive to check that there are such rules giving rise to the following pairs $(\beta, \chi')$:

$$((p, p, p - 2), 1), ((p, 2, p - 1), \psi_{1}^{-1}), ((p, p, p), \psi_{2}^{-1}).$$
For example, here are two instances of the second rule:
\[
\left( \psi_1 \psi_2^{p-1} \right) \sim \left( \psi_1^2 \psi_0^p \psi_2^{p-1} \right) \psi_1^{-1}
\]
and
\[
\left( \psi_1' \psi_2^{p-1} \right) \sim \left( \psi_2'^{p-1} \psi_0^p \psi_2^{p-1} \right) \psi_1^{-1}
\]
In the end, these rules consist of multiple uses of the identity
\[
\psi_j + 1 = \psi_j \psi_{j+1} \cdots \psi_{p-1}
\]
when \( \alpha(i) = 0 \) (\( \alpha(i) = 1 \) is allowed if \( \psi_i \) is itself to be expanded in this manner!). Of course this works equally well for \( \psi_{(j+1)}' \). To compare with the formalism below, let us indicate in each case the corresponding choice of \( I \):
\[
0_{-1}, 1_{-1}, p-1, 0_{-1}, 1_{p-1}, 0_{-1}, 1_{p-1}
\]
Note that the last of these is not covered by the \( R_{ext,p} \) we defined above. In fact, it is not hard to see that axiom A4 below could be weakened to:

A4' If an \( I \)-interval is positive, its successor does not lie in any \( I \)-interval.

This corresponds to removing the condition \( m_s \neq 0 \) in the definition of \( R_{ext,p} \) above. If we denote this modified version of \( R_{ext,p} \) by \( R'_{ext,p} \) then it is clear that any multi-valued function between \( R_{ext,p} \) and \( R'_{ext,p} \) (i.e., such that there is a containment pointwise) satisfies thm. 11.3(ii).

* * *

For our purposes, an interval in \( \mathbb{Z}/f \) is any “stretch” of numbers \([i, j] = \{i, i+1, \ldots, j\}\) in \( \mathbb{Z}/f \). The start and end points are remembered so that, for example, \([0, p-1] \neq [1, 0]\) even though the underlying sets are the same. The successor of an interval \([i, j]\) is \( j+1 \).

Suppose that \( \alpha \) is a function \( \mathbb{Z}/f \to \{0, 1, \ldots, p-1\} \), and suppose that \( I \) a collection of disjoint intervals \( I \) in \( \mathbb{Z}/f \), each labelled with a sign (thought of as pertaining to the entry following that interval). Define the set \( \mathcal{L}_{[0,p-1]} \) to consist of all \((\alpha, I)\) which satisfy the following rules:

A1 For each interval \( I \in \mathcal{I} \), \( \alpha(I) \subset \{0, 1\} \).
A2 If \( i \in \bigcup \mathcal{I} \) then \( \alpha(i) = 1 \) if and only if \( i \) is start point of an \( \mathcal{I} \)-interval and \( i - 1 \notin \bigcup \mathcal{I} \).
A3 If \( i \notin \bigcup \mathcal{I} \) and \( \alpha(i) = 0 \), then \( i - 1 \in \bigcup \mathcal{I} \).
A4 If an \( \mathcal{I} \)-interval is positive, its successor does not lie in any \( \mathcal{I} \)-interval and has \( \alpha \)-value in \([0, p-2]\).
A5 If an \( \mathcal{I} \)-interval is negative, its successor lies in another \( \mathcal{I} \)-interval or has \( \alpha \)-value in \([2, p-1]\).

Note that every function \( \alpha : \mathbb{Z}/f \to \{0, 1, \ldots, p-1\} \) can be equipped with intervals and signs satisfying these rules.
Similarly, suppose that $\beta$ is a function $\mathbb{Z}/f \to \{1, 2, \ldots, p\}$, and suppose that $\mathcal{I}$ a collection of disjoint intervals in $\mathbb{Z}/f$, each labelled with a sign (thought of as pertaining to the entry following that interval). Define the set $\mathcal{L}_{[1,p]}$ to consist of all $(\beta, \mathcal{I})$ which satisfy the following rules:

B1 For each interval $I \in \mathcal{I}$, $\beta(I) \subset \{p-1, p\}$.
B2 The set of start points of $\mathcal{I}$-intervals is $\beta^{-1}(p)$.
B3 If an $\mathcal{I}$-interval is positive, its successor does not lie in any $\mathcal{I}$-interval and has $\beta$-value in $[1, p-1]$.
B4 If an $\mathcal{I}$-interval is negative, its successor lies in another $\mathcal{I}$-interval or has $\beta$-value in $[1, p-2]$.

Note that every function $\beta : \mathbb{Z}/f \to \{1, 2, \ldots, p\}$ can be equipped with intervals and signs satisfying these rules.

To define a map $\phi : \mathcal{L}_{[0,p-1]} \to \mathcal{L}_{[1,p]}$, represent $\alpha$ as the string of numbers $\alpha(0), \alpha(1), \ldots, \alpha(f-1)$; underline each $\mathcal{I}$-interval and put the corresponding sign just after the last entry of the interval. In this way the function $\phi$ has the following effect on each interval and its successor (it leaves all other entries unchanged):

$(1), 0, 0, 0, \ldots, a, \ldots, p, p-1, \ldots, p-1, a \pm 1, \ldots, 0, 0, 1, 0, \ldots \mapsto \ldots, p-1, p-1, p-1, \ldots$

**Lemma 11.5.** The map $\phi$ is well defined and in fact a bijection.

**Lemma 11.6.** Suppose that $\alpha : \mathbb{Z}/f \to \{0, 1, \ldots, p-1\}$. Then the following are equivalent for a subset $S \subset \mathbb{Z}/f$:

(i) $S \in S(F_{\bar{p}-\bar{\mathcal{I}}-\bar{a}, \bar{x}})$ for some $\bar{x}$.
(ii) $S \in S(F_{\bar{p}-\bar{\mathcal{I}}-\bar{a}, \bar{x}})$ for all $\bar{x}$.
(iii) $S$ is the set of successors of positive intervals in $\mathcal{I}$ for some $\mathcal{I}$ with $(\alpha, \mathcal{I}) \in \mathcal{L}_{[0,p-1]}$.

**Proof of the theorem.** (i) This is a straightforward application of lemma [11.4].

First consider the niveau 1 case. Suppose $F \in W'_p(\rho)$ and $F$ regular. By twisting, we can assume without loss of generality that $F = F_{\bar{b}-\bar{\mathcal{I}}, \bar{0}}$ ($1 \leq b_i \leq p-1$) and

$$\rho|_{\bar{I}} \sim \left( \prod_j \psi_i^{b_j} \prod_J \psi_i^{b_j} \right)$$

for some $J \subset \mathbb{Z}/f$. By lemma [11.4], the regular Serre weight $F_{\bar{p}-\bar{\mathcal{I}}-\bar{b}, \bar{0}}$ is a constituent of $V_p(\rho|_{\bar{I}})$. Applying $\mathcal{R}_p$ produces $F_{\bar{b}-\bar{\mathcal{I}}, \bar{0}}$. Reversing the argument yields the other inclusion.

The niveau 2 case works exactly the same way.

(ii) **Step 1:** Show that $\mathcal{R}_{ext,p}(F) \subset W'_p(\rho)$ if $F$ is a constituent of $V_p(\rho|_{\bar{I}})$.

Without loss of generality (twisting $\rho$ and $F$) we may assume that $F = F_{\bar{m}, \bar{0}}$ ($0 \leq m_i \leq p-1$). If $\rho|_{\bar{I}}$ has niveau 1, then by lemma [11.4] we can
write
\begin{equation}
\rho|_{I_p} \sim \left( \prod_J \psi_i^{p-1-m_i} \right) \prod_{J \subset S} \psi_i^{m_i}
\end{equation}
for some subset \( J \subset \mathbb{Z}/f \). Define \( \alpha : \mathbb{Z}/f \to \{0, 1, \ldots, p-1\}, i \mapsto p-1-m_i \). Given \( S \in S(F) \), we can by lemma 11.6 choose a collection \( I \) of signed intervals such that \((\alpha, I) \in \mathcal{L}_{[0,p-1]}\) and \( S \) is the set of successors of positive \( I \)-intervals. Let \( J_+ \) (resp. \( J_- \)) denote those elements of \( J \) that succeed positive (resp. negative) intervals of \( I \). Similarly define \( J_+^c \) and \( J_-^c \). Let \( J_0 \) (resp. \( J_0^c \)) denote those elements of \( J \) (resp. \( J^c \)) that do not lie in any interval of \( I \). Note that \( S = J_+ \cup J_- \). Then
\begin{equation}
\rho|_{I_p} \sim \left( \prod_{J_+} \psi_i^{\alpha(i)+1} \prod_{J_0 \setminus (J_+ \cup J_-)} \psi_i^{\alpha(i)} \prod_{J_0 \cap J_-} \psi_i^{\alpha(i)-1} \prod_{j+1 \in J_+ \cup J_-} (\psi_i^{p\psi_j} \psi_{i+1}^{p-1} \cdots \psi_{j}^{p-1}) \right)
\end{equation}
and \( \chi_2 \) is obtained by interchanging the roles of \( J \) and \( J^c \). Note that each \( \psi_i \) appears with non-zero exponent in precisely one of \( \chi_1 \), \( \chi_2 \) (the way they are expressed here); call this non-zero exponent \( \beta(i) \). It is not hard to see that \( \phi(\alpha, I) = (\beta, I) \). Thus
\begin{equation}
\chi_1 = \prod_L \psi_i^{\beta(i)} \quad \chi_2 = \prod_{L^c} \psi_i^{\beta(i)}
\end{equation}
for some \( L \subset \mathbb{Z}/f \) and all exponents \( \beta(i) \) are in \([1, p]\), so \((\chi_1, \chi_2) \) gives rise to a Serre weight \( F(A, B) \in W_p^2(\rho) \) (by (11.1)). Combining equations (11.7) and (11.8) we find that
\[ \det(\rho|_{I_p} \cdot \prod \psi_i^{-m_i}) = \psi_0^{-\sum m_ip^i} = \psi_0^{\sum(\beta(i)-2 \cdot 1_0(i))p^i}. \]
Using this, we easily see that \( F(A, B) \) satisfies
\[ A = -\sum_{S^c} p^i, \quad B = \sum m_ip^i - \sum_{S} p^i \pmod{p^f - 1}. \]
We are done except for showing that any other weight \( F(A', B') \) satisfying these congruences is in the conjectured weight set. But these congruences determine \( F(A, B) \) except for the pairs \( \{F(x, x), F(x + p^f - 1, x)\} \) and for all \( x, F(x, x) \in W_p^2(\rho) \) if and only if \( F(x + p^f - 1, x) \in W_p^2(\rho) \) (this follows directly from the definition). Therefore \( \mathcal{R}_{ext, p}(F) \subset W_p^2(\rho) \).

If \( \rho|_{I_p} \) has niveau 2, then
\begin{equation}
\rho|_{I_p} \sim \left( \prod_J \psi_i^{p-1-m_i} \right) \prod_{J \subset S} \psi_i^{m_i}
\end{equation}
for some \( J \subset \mathbb{Z}/2f \) projecting bijectively onto \( \mathbb{Z}/f \). The argument is now formally identical to the niveau 1 case provided we replace each \( \psi_i \) by \( \psi_i' \).
and “$[i,j] \in \mathcal{I}$” in the subscript of the right-most product in the expression for $\chi_1$ by “$[i,j] \in \mathcal{I}$”, where $\mathcal{I}$ is the set of intervals in $\mathbb{Z}/2f$ which project bijectively onto the $\mathcal{I}$-intervals in $\mathbb{Z}/f$.

**Step 2**: Show that all weights $F$ in $W^r_p(\rho)$ are obtained in this way.

If $\rho|_{I_p}$ has niveau 1, then we can twist by characters and assume without loss of generality that $F = F_{\beta-1,0} (1 \leq \beta(i) \leq p)$ and

$$\rho|_{I_p} \sim \left( \prod_{L} \psi_{i}^{\beta(i)} \right)$$

for some $L \subset \mathbb{Z}/f$. Define a collection $\mathcal{I}$ of disjoint signed intervals in $\mathbb{Z}/f$ which is in bijection with $\beta^{-1}(p)$, as follows. Whenever $\beta(i) = p$ and $i \in L$ (resp. $L^c$) choose $j$ such that all numbers in $\beta([i,j]-\{i\}) \subset \{p-1\}$, $[i,j] \subset L$ (resp. $L^c$) and $j$ is maximal with respect to these properties (i.e., $j$ cannot be replaced by $j + 1$). In that case $[i,j]$ is the $\mathcal{I}$-interval corresponding to $i \in \beta^{-1}(p)$. We let it be negative if and only if $\beta(j+1) = p$ or $j+1 \in L$ (resp. $L^c$). Observe that $(\beta, \mathcal{I}) \in L_{[1,p]}$.

Let $\Sigma_L$ (resp. $\Sigma_{L^c}$) be the set of successors of $\mathcal{I}$-intervals contained in $L$ (resp. $L^c$). The notations $L_0$, $L_0^c$ have the same meaning as in the previous part. Note that $S = \Sigma_L \cap L_0 \cup \Sigma_{L^c} \cap L_0$ is the set of successors of positive $\mathcal{I}$-intervals. We see that

$$\rho|_{I_p} \sim \left( \chi_1 \chi_2 \right) \prod_{S} \psi_i$$

where

$$\chi_1 = \prod_{L \in \Sigma_L \cap L_0} \psi_{i}^{\beta(i)-1} \prod_{L \in \Sigma_L \cap L_0^c} \psi_{i}^{\beta(i)} \prod_{L \in \Sigma_{L^c} \cap L_0} \psi_{i}^{\beta(i)+1} \prod_{L \in \Sigma_{L^c} \cap L_0^c} \psi_{i}$$

and $\chi_2$ is obtained by interchanging the roles of $L$ and $L^c$. Every $\psi_i$ occurs with a non-zero exponent in at most one of $\chi_1$, $\chi_2$ (the way they are expressed here): call this exponent $\alpha(i) \in \{0,1,\ldots,p-1\}$. By lemma 11.4 taking into account the twist, this decomposition shows that $F' = F_{\beta-1-\alpha,\alpha+1}$ is a constituent of $\tilde{V}_p(\rho|_{I_p})$ (here $1_S$ is the characteristic function of $S$).

It is not hard to see that $\phi^{-1}(\beta, \mathcal{I}) = (\alpha, \mathcal{I})$. In particular, by lemma 11.6 $S \in \mathcal{F}(F')$. Equations (11.9), (11.10) yield

$$\det(\rho|_{I_p}) = \psi_0^{\sum (\alpha(i)+21\mathbb{S}(i))p^i} = \psi_0^{\sum \beta(i)p^i}.$$  

We see that the weight in $\mathcal{R}_{\text{ext},p}(F')$ corresponding to $S \in \mathcal{F}(F')$ is $F_{\beta-1,0} = F$, and we are done.

If $\rho|_{I_p}$ has niveau 2, the argument is completely analogous (as in Step 1).

\textit{Proof of lemma 11.4} (i) First let us show the implication “$\Rightarrow$”. Without loss of generality,

$$\rho|_{I_p} \sim \left( \prod \psi_{i}^{\alpha(i)} \right)_{1}$$

\textit{Proof of lemma 11.4} (ii) If $\rho|_{I_p}$ has niveau 1 and $\Sigma = \{\alpha \mid \alpha \geq 1\}$, then there exists a finite set of disjoint $\mathcal{I}$-intervals $\mathcal{I}_1, \ldots, \mathcal{I}_k$ such that

$$\rho|_{I_p} \sim \left( \prod_{i \in \mathcal{I}} \psi_{i}^{\beta(i)} \prod_{j \in \mathcal{I}_1} \psi_{j}^{\gamma(j)} \ldots \prod_{l \in \mathcal{I}_k} \psi_{l}^{\delta(l)} \right).$$

We see that $\rho|_{I_p}$ has niveau 1. Without loss of generality, $\rho = \psi_{1}^{\gamma(1)} \ldots \psi_{p}^{\gamma(p)}$. Let $\nu_1, \ldots, \nu_k \in \mathbb{Z}/p$ be the exponents of $\psi_1, \ldots, \psi_p$. We may assume without loss of generality that $\nu_1, \ldots, \nu_k$ are non-negative. We see that $\rho|_{I_p}$ has niveau 1.

\textit{Proof of lemma 11.4} (iii) If $\rho|_{I_p}$ has niveau 1, then there exists a finite set of disjoint $\mathcal{I}$-intervals $\mathcal{I}_1, \ldots, \mathcal{I}_k$ such that

$$\rho|_{I_p} \sim \left( \prod_{i \in \mathcal{I}} \psi_{i}^{\beta(i)} \prod_{j \in \mathcal{I}_1} \psi_{j}^{\gamma(j)} \ldots \prod_{l \in \mathcal{I}_k} \psi_{l}^{\delta(l)} \right).$$

We see that $\rho|_{I_p}$ has niveau 1. Without loss of generality, $\rho = \psi_{1}^{\gamma(1)} \ldots \psi_{p}^{\gamma(p)}$. Let $\nu_1, \ldots, \nu_k \in \mathbb{Z}/p$ be the exponents of $\psi_1, \ldots, \psi_p$. We may assume without loss of generality that $\nu_1, \ldots, \nu_k$ are non-negative. We see that $\rho|_{I_p}$ has niveau 1.
for some $0 \leq n_i \leq p - 1$. By \cite{Dia}, prop. 1.1, the constituents of $V_\bar{\rho}(\rho|_{I_p})$ are the $F_{\bar{c}_j,\bar{d}_j}$ where $J \subset \mathbb{Z}/f$ and

$$c_{j,i} = \begin{cases} n_i + \delta_j(i) - 1 & \text{if } i \in J \\ p - 1 - n_i - \delta_j(i) & \text{if } i \not\in J \end{cases}$$

$$d_{j,i} = \begin{cases} 0 & \text{if } i \in J \\ n_i + \delta_j(i) & \text{if } i \not\in J \end{cases}$$

where $\delta_j$ is the characteristic function of \{i + 1 : i \in J\}. Also, the convention is that $F_{\bar{c}_j,\bar{d}_j} = (0)$ if $c_{j,i} = -1$ for some $i$. Now note that

$$\rho|_{I_p} \sim ( \prod_{j \in c} \psi_i^{n_i + \delta_j(i)} \prod_j \psi_i^{p - n_i - \delta_j(i)} ) \prod_j \psi_i^{n_i + \delta_j(i) - 1} \prod_{j \in d} \psi_i^{p - 1}.$$ 

Conversely, suppose without loss of generality that $\rho|_{I_p}$ is as in the statement of the lemma with $\bar{b} = 0$. Note that whenever $m_i = p - 1$ it is irrelevant whether $i \in J$ or not. Thus for all such $i$ we can prescribe whether or not $i \in J$. There is a unique way to alter $J$ in this manner such that for all $i$ with $m_i = p - 1$, $i \in J \iff i - 1 \in J$ (the latter is equivalent to $\delta_j(i) = 1$). Note that

$$V_\bar{\rho}(\rho|_{I_p}) \cong I( \prod_{j \in c} \lambda_i^{p - 1 - m_i} \prod_j \lambda_i^{m_i + 1 - p}, 1 ) \otimes \prod_j \lambda_i^{m_i} \prod_j \lambda_i^{p - 1 - m_i}$$

$$\cong I( \prod_{j \in c} \lambda_i^{p - 1 - m_i - \delta_j(i)} \prod_j \lambda_i^{m_i + 1 - \delta_j(i)}, 1 ) \otimes \prod_j \lambda_i^{m_i} \prod_j \lambda_i^{p - 1 - m_i}.$$

By our choice of $J$, all exponents of the first character in the induction are contained in $\{0, 1, \ldots, p - 1\}$. It follows from \cite{Dia}, prop. 1.1 (using the same subset $J$) that $F_{\bar{m},\bar{1}}$ is a constituent of $V_\bar{\rho}(\rho|_{I_p})$, as required.

(ii) This works completely analogously, it is only more cumbersome to write out. Note that we can assume $\bar{m} \neq \bar{b} - \bar{1}$ as on the one hand

$$\dim F_{\bar{b} - \bar{1},\bar{b}} = p^f > p^f - 1 = \dim V_\bar{\rho}(\rho|_{I_p})$$

and on the other hand $\rho|_{I_p}$ cannot be unramified up to twist (being of niveau 2).

Proof of lemma \cite{LL,B} This is straightforward. \hfill \Box

Proof of lemma \cite{LL,B}  Note that the first two statements are equivalent, by the definition of $\mathcal{S}(F)$, to

(i') For all $s \in S$,

(a) $\alpha(s) \neq p - 1$.

(b) There is an $i \in \mathbb{Z}/f$ such that $[i, s - 1] \cap S = \emptyset$ and $\alpha(i) = 0$, $\alpha(i + 1) = \cdots = \alpha(s - 1) = 1$.

We will now show that (i') $\iff$ (iii).

First suppose that $(\alpha, \mathcal{I}) \in \mathcal{L}_{[0, p - 1]}$ and let $S$ be the set of successors of positive intervals. Then by property A4 (see p. \cite{M}), $\alpha(s) \neq p - 1$ if $s \in S$. 

Moreover, $\alpha(s - 1) \in \{0, 1\}$ and $s - 1 \not\in S$ (as $s - 1$ is in an interval). If it is 1, by property A2 the preceding entry lies in a different (negative) interval and iterating this process gives the desired interval $[i, s - 1]$. Note that the process has to stop (i.e., eventually we hit a 0) because $s \in S$ cannot itself lie in an interval (by A4).

Conversely, suppose given $S$ satisfying (i) and (ii). Here is a way to define $I$ having $S$ as set of successors of positive intervals and such that $(\alpha, I) \in L_{[0,p-1]}$ (in fact it is the unique way). It is easier to define $\bigcup I$ first: we let $i \in \bigcup I$ if and only if there is a $j$ such that $[j, i] \subset S^c$ and $\alpha(j) = 0, \alpha(j + 1) = \cdots = \alpha(i) = 1$ (in particular, this whole interval will be contained in $\bigcup I$). We let $i \in \bigcup I$ be start point of an $I$-interval if and only if $i - 1 \not\in \bigcup I$ or $i - 1 \in \bigcup I$ and $\alpha(i) = 1$. We let an $I$-interval be positive if and only if its successor is in $S$.

It is straightforward to see that $(\alpha, I) \in L_{[0,p-1]}$; by definition $S$ is the set of successors of positive intervals. \qed
