\(^{1}\)Department of Preventive Veterinary Medicine, College of Veterinary Medicine, Shandong Agricultural University, Taian, China, \(^2\)Shandong Provincial Key Laboratory of Animal Biotechnology and Disease Control and Prevention, Shandong Agricultural University, Taian, China, \(^3\)China Animal Disease Control Center, Beijing, China

We investigated the prevalence of salmonellosis on 17 poultry breeding farms in nine Chinese provinces (Shandong, Jiangsu, Anhui, Zhejiang, Fujian, Guangdong, Yunnan, Sichuan, and Chongqing). Altogether, 3,508 samples from poultry breeding farms were collected in 2019, including 1,400 from cloaca swabs, 210 from feed, 1,688 from chicken embryos, and 210 from water. All the samples were subjected to bacterial isolation and culture, and bacterial species were identified by polymerase chain reaction. Serotyping, multilocus sequence typing (MLST), and drug-resistance phenotyping were performed on the isolates identified as *Salmonella*. Altogether, 126 *Salmonella* strains were detected in the 3,508 samples and the positivity rate for the samples was 3.59%. Among all the strains, 95 Salmonella isolates were selected for antimicrobial susceptibility test, resistance gene detection, serotyping, and genotyping. *S. gallinarum-pullorum* (57/95, 60.00%), *S. enteritidis* (22/95, 23.16%), and *S. agona* (16/95, 16.84%) serotypes were identified. The MLST classification showed that the 95 Salmonella strains fell into the following five sequence types (STs): ST92 (37/95, 38.95%), ST11 (22/95, 23.16%), ST2151 (19/95, 20.00%), ST13 (16/95, 16.84%), and ST470 (1/95, 1.05%). Apart from ST13, the other four STs shared close genetic relationships, and the genetic direction was ST11-ST470-ST92-ST2151. The resistance rates in the 95 isolates were 100% (95/95) for erythromycin, 68.42% (65/95) for tetracycline, and 53.68% (51/95) for streptomycin and ampicillin, respectively. The isolates were sensitive to polymyxin and sulfamethoxazole. Multi-drug resistance was seen in 70.53% (67/95) of the isolates. ß-lactam-, aminoglycoside- and sulfonamide-encoding resistance genes were detected by PCR. The detection rate for *bla*\(_{TEM}\) and *sul3* was 100% (95/95), whereas *sul2* and *aaC4* had rates of 52.63 and 23.16%, respectively. These results indicate that some of the salmonellosis seen in Chinese breeding chicken farms may be caused by infection with *S. gallinarum-pullorum*, *S. enteritidis*, and *S. agona*. They also show that some *Salmonella* isolates have multi-drug resistance phenotypes and carry multi-drug resistance genes.

**Keywords:** *Salmonella*, multidrug resistance, MLST, phenotypes, chickens, breeder farms
INTRODUCTION

Salmonella is a food-borne disease-causing zoonotic pathogen (1), and its occurrence has frequently been reported in recent years (2, 3). More than 2,600 Salmonella serotypes have been identified and recorded (4). According to the World Health Organization (WHO), with nearly one-tenth of the world’s population becoming infected each year and around 33 million deaths (http://www.who.int/mediacentre/factsheets/fs139/en/). Most cases occur in older adults and in immunocompromised people (5, 6), and it is estimated that in 2017 Salmonella enterocolitis was responsible for 95.1 million cases and killed 50,771 people (7–9). In addition to diarrhea, 535,000 cases of non-typhoidal Salmonella invasive disease have occurred, and an estimated 77,500 people have died (10). At present, antibiotic therapy remains the main prevention and treatment method for salmonellosis. However, the long-term and unreasonable use of antibiotics has caused Salmonella to develop widespread and strong resistance to these agents (11). Drug resistant bacteria can also spread to humans, leading to public health problems (12).

Various molecular typing techniques have been widely used in the field of microbiology to track the origins of pathogenic bacteria (13), the most widely of which used are multilocus sequence typing (MLST) and pulsed field gel electrophoresis (PFGE). MLST is fast and convenient, producing reliable high resolution data, and easy real-time internet sharing (14). PFGE is recognized by laboratories around the world for its high resolution and repeatability. But PFGE does not have a strict and uniform international naming standard, making it difficult to achieve data sharing with it. In recent years, a large number of epidemiological surveys on Salmonella have emerged in China. However, researchers were more inclined to conduct their epidemiological Salmonella surveys on commercial broiler sales chains where sick birds appeared than on healthier chains (15–17). Therefore, data from epidemiological surveys on Salmonella in domestic poultry farms, especially chicken breeder flocks, are incomplete.

Here, we collected 3,508 samples from 17 poultry breeding farms in nine Chinese provinces in 2019. We investigated the drug-resistance genes, drug-resistance phenotypes, and genetic relationships among the Salmonella isolates we collected. We comprehensively and systematically studied the epidemiological characteristics of Salmonella, with the aim of improving the molecular typing network database in China and providing relevant data with which to support the prevention and control of Salmonella in China.

MATERIALS AND METHODS

Sample Collection

From May to July 2019, 3,208 samples were collected from 14 poultry breeding farms in Jiangsu, Anhui, Zhejiang, Fujian, Guangdong, Yunnan, Chongqing, and Sichuan Province, China. They included 1,400 cloacal swab samples, 210 animal feed samples, 1,388 embryo samples and 210 water samples. An additional 300 chicken embryo samples were obtained from three chicken breeding farms in Shandong Province, China (Figure 1A).

Isolating and Serotyping Salmonella

Buffered peptone water (4.5 mL) (BPW, Haibo Biotechnology, Qingdao, China) was added to each sample (0.5 g) for pre-enrichment, according to a previously described method (18). After incubation at 37°C for 8–12 h, 0.5 mL of each pre-enriched culture was incubated in 4.5 ml of Tetrathionate Broth Buffer (TTB, Haibo Biotechnology) at 37°C for 24 h. After selective enrichment, one loopful of each broth culture was streaked onto xylose lysine tergitol 4 (XLT4, Haibo Biotechnology) agar and the plates were incubated at 37°C for 24–36 h. The presumptive Salmonella colonies were identified by polymerase chain reaction (PCR) assays using invA primers (19). The invA gene has a conserved sequence in Salmonella species and can therefore be used to detect and validate Salmonella strains (20). Here, invA primers (19) (F: 5′-ACAGTGCTCAGTTTACGGCGATT-3′, R: 5′-AGACAGCTGTTACGTGATA-3′) were used for PCR. The PCR cycling conditions were as follows: 1 denaturation cycle at 95°C for 5 min, 30 cycles of denaturation at 95°C for 30 s, followed by annealing at 56°C for 30 s and elongation at 72°C for 1 min, and a final 10 min elongation cycle at 72°C. Positive colonies were subsequently confirmed using a microbeal mass spectrometer (IVD MALDI Biotyper, Bruker Bremen, Germany).

Salmonella Serotyping

After being resuscitated on XLT4 medium, all the Salmonella isolates were serotyped according to the Kauffmann-White scheme by slide agglutination with O and H antigens (Tianrun Bio-Pharmaceutical, Ningbo, China). Normal saline was used as a negative control, and plate agglutination reactions were considered Salmonella positive. The Salmonella strains were PCR-identified using DNA as the template and Ipaj (F: 5′-TACCTGTTCTGCGCCGTGA-3′, R: 5′-ACCCCTGCAAACTCGAAATC-3′) (21) as primers for detecting S. gallinarum-pullorum.

Antimicrobial Susceptibility Testing

The Kirby-Bauer disk diffusion method, as described by the Clinical and Laboratory Standards Institute (CLSI), was used to test the susceptibility of the Salmonella isolates to 14 commonly used antibiotics, including polymyxin B (PB, 300 IU), sulfamethoxazole (SXT, 25 µg), fleroxenil (30 µg), ofloxacin (5 µg), cefoxitin (30 µg), doxycycline (30 µg), amoxicillin (20 µg), tetracycline (TE, 30 µg), streptomycin (STR, 10 µg), gentamycin (10 µg), erythromycin (EM, 15 µg), ceftazidime (CAZ, 30 µg), ampicillin (AM, 10 µg), and gatifloxacin (5 µg). The results were interpreted according to the standard guidelines from the CLSI (22). Salmonella isolates that were resistant to more than three antimicrobial classes were defined as multidrug-resistant (MDR) isolates.

Detecting Drug-Resistance Genes

Bacterial DNA was extracted from the samples using a Bacterial Genome Kit (Bieteke, Beijing, China), according to the manufacturer’s instructions. The β-lactam genes (blaTEM,
FIGURE 1 | Geographical Map of the Chinese Sampling Sites and Proportions of the Serotypes for the Salmonella Isolates (A). A total of 3,208 samples were collected from 14 poultry breeding farms in Jiangsu, Zhejiang, Anhui, Fujian, Guangdong, Yunnan, Chongqing, and Sichuan Provinces, China. They included 1,400 cloacal swab samples, 210 feed samples, 1,388 embryo samples, and 210 water samples. An additional 300 chicken embryo samples were obtained from three chicken breeding farms in Shandong Province, China (B). The 95 isolates included 57 strains of S. gallinarum-pullorum (60.00%, 57/95), 22 strains of S. enteritidis (23.16%, 22/95), and 16 strains of S. agona (16.84%, 16/95).

Detecting Class I Integrons

Class I integron-targeting primers were designed based on previously described sequences (28). After DNA gel extraction kit (Vazyme Biotech, Nanjing, China) purification, the class I integron-positive DNA samples were sequenced (Sangon Biotech, Shanghai, China). The DNA sequences obtained were compared with those in GenBank (https://www.ncbi.nlm.nih.gov/genbank/) using the Basic Local Alignment Search Tool to determine the gene cassettes within the variable region of the class I integrons.

MLST

Seven housekeeping genes (aroC, dnaN, hemD, hisD, purE, sucA, and thrA) were used to characterize the Salmonella isolates using MLST (http://mlst.warwick.ac.uk/mlst/). The protocols from the MLST homepage were used, including the PCR conditions...

and primer sequence information (http://mlst.warwick.ac.uk/mlst/dbs/Senterica). PCR products were purified and sequenced (Sangon Biotech). The nucleic acid sequences corresponding to the allele values of the seven pairs of Salmonella housekeeping genes were downloaded from Pubmlst (https://pubmlst.org/), and BioEdit v7.0.9 software was used to construct a local gene bank for them. Genes from the gene library were aligned to obtain the allele values of the isolated strains and their corresponding ST types. The sequence types were assigned according to the MLST online scheme (http://mlst.warwick.ac.uk/mlst/dbs/Senterica), and the results of the eBURST map were constructed by Phyloviz (https://online.phyloviz.net/index).

RESULTS

Isolation and Salmonella Serotyping

As described in the methods section, samples of the diseased materials were subjected to two-step enrichment using BPW and TTB, and a single colony was obtained by an three-line method on XLT4 medium. Colorless, translucent small colonies were observed on the plates, and some had smooth black cores and very narrow transparent bands around them. DNA was extracted from the isolated bacterial colonies, and PCR was performed with invA primers for Salmonella detection. After the PCR detection and the microbiological mass spectrometer verification, 126 Salmonella strains were isolated, with the detection rate of 3.59% (126/3508; Table 2). The isolating rates among different sample source were shown as: 6.27% (104/1688) in chicken embryo samples, 2.86% (6/210) in water samples, 1.14% (16/1400) in cloaca swabs, 0% (0/210) in feed samples. Salmonella was not detected in samples from Jiangsu and Sichuan province. Among all the isolates, 54 strains were recovered from samples of Shandong province, with the highest isolation rate of 18% (54/300), while a total of 72 Salmonella isolates were isolated from the other 6 provinces. In this study, a total of 95 strains, consisted of 23 randomly selected Shandong isolates and the aforementioned 72 isolates, were collected for subsequent tests.

Salmonella Serotyping Results

The Ningbo Tianrun Serum Diagnostic Kit test results showed that the O antigens of the 95 Salmonella strains were O9, O12 (79/95) and O4, O12 (16/95). The results from the semi-solid puncture tests showed that 38/95 isolates had flagella and 57 had no flagella. The serum diagnostic kit results showed that the H antigens from the 38 isolates were Hg, m (22/38) and Hs (16/38). The kit’s results when combined with the PCR results showed...
that the 95 isolates included 57 S. gallinarum-pullorum strains (60.00%, 57/95), 22 S. enteritidis strains (23.16%, 22/95), and 16 S. agona strains (16.84 %, 16/95) (Figure 1B).

**Antibiotic Resistance and MDR Profiles**

The KB method was used to count the diameters of the inhibition zones and to determine growth inhibition to 14 common antibacterial drugs in the 95 Salmonella strains according to the 2018 edition of the CLSI standards. The resistance rates in the 95 isolates were 100% (95/95) for erythromycin, 68.42% (65/95) for tetracycline, and 53.68% (51/95) for STR and AM, respectively. The AM resistance rate for the 95 isolates was 53.68% (51/95), and they were all sensitive to PB and SXT (Figure 2A).

We next statistically analyzed the drug resistance spectrum and multiple drug resistance in the isolated bacteria (Figure 2B). The MDR statistics showed that 70.53% (67/95) of the strains were resistant to three or more drug types, indicating that drug resistance in the isolated bacteria is prevalent with 38 different resistance patterns identified (Table 3). The drug-resistance spectrum was broad, and the most common pattern in seven of the isolates involved AMX-STR-TE-AM-CAZ-EM. The serotypes and resistance patterns were not significantly correlated. According to the resistance profile heat map (Figure 3), drug-resistant Salmonella isolated from the three...
Prevalence of Antibiotic Resistance Genes

Using the DNA from each isolate as the template, PCR was used to detect the carriage status of the isolates to 18 drug resistance genes. Four different drug resistance genes were detected in DNA from the isolates, including those encoding β-lactams, aminoglycosides, and sulfonamides. The highest detection rates were seen for blaTEM and sul3 (100%, 95/95), followed by sul2 and aacC4 (52.63 and 23.16%, respectively) (Figure 4).

detection of Class I Integrons

PCR testing detected no class I integrants in the DNA from the isolates; therefore none of the strains from this study carried class I integrants.

MLST

MLST classification showed that the 95 Salmonella strains fell into five ST types: ST92 (37/95, 38.95%), ST11 (22/95, 23.16%), ST2151 (19/95, 20.00%), ST13 (16/95, 16.84%), and ST470 (1/95, 1.05%) (Figure 5A). The results of the eBURST map showed that isolate ST11 was a cloned progenitor, isolates ST92 and ST2151 were subcloned groups from isolate ST11. Apart from ST13, the other four STs have close genetic relationships. The genetic direction was determined to be ST11-ST470-ST92-ST2151 (Figure 5B), with ST11 being the core sequence type.

DISCUSSION

An important transmission route for Salmonella is vertical transmission. Therefore, chicken breeder farms are required to actively prevent, control, and work toward eliminating Salmonella infections on them. Once breeder chickens become infected with Salmonella, a “magnification effect” can occur as the generations expand. China has listed Salmonellosis as a priority disease control species in the National Medium and Long-Term Animal Disease Prevention and Control Plan (2012–2020) (http://www.gov.cn/zwgk/2012-05/25/content_2145581.htm), which requires all chicken farms across the country to meet the standards required to eliminate chicken salmonellosis by 2020. Hence, investigating salmonella epidemics on breeding farms is particularly important.

To investigate the prevalence and characteristics of Salmonella on Chinese poultry breeding farms requires information about drug-resistance genes, and the phenotypic characteristics of the isolates collected from them and their relationships. In this study, from May to July 2019, 3,508 samples from breeding farms were collected, including 1,400 cloaca swabs, 210 feed samples, 1,688 chicken embryo samples, and 210 water samples. The samples came from 14 breeder farms in eight provinces (Jiangsu, Anhui, Zhejiang, Fujian, Guangdong, Yunnan, Chongqing, and Sichuan) and three breeder flocks in Shandong Province. We detected 126 Salmonella strains in the 3,508 samples, a positivity rate of 3.59%. The positive isolation rate was very low, which may reflect the fact that the efforts made to prevent and control animal diseases in China are transitioning from effective control to gradual purification and elimination. In this investigation, especially in several breeder flocks in Jiangsu and Sichuan, Salmonella elimination has been done well. In contrast, the three local breed chicken breeder flocks in Shandong were more seriously contaminated with salmonella. It indicated that more attention should be paid on salmonella purification in local chicken breeds.

From the 1990s onwards, pullorum disease has seriously threatened the poultry industry (29). S. pullorum infection is still threatening the poultry farming industry and related industries in developing countries including China (30), resulting

chicken farms in Shandong Province had the highest drug-resistance rates.
in huge economic losses in these countries. Among the three serotypes identified in this study, *S. gallinarum-pullorum* (57/95, 60.00%) still dominates, with *S. enteritidis* (22/95, 23.16%) and *S. agona* (16/95, 16.84%) ranking second and third. In contrast, *S. Enteritidis, S. Indiana*, and *S. Typhimurium* are more common in the Chinese chicken retail industry.

After serotype identification, we used molecular typing to further analyze the genetic relationships among the isolates. Various molecular typing techniques are widely used in the microbiology field to track the origin of pathogenic bacteria (13), from which the most commonly used techniques are MLST and PFGE. The high resolution and repeatability of PFGE has been recognized by laboratories around the world, but PFGE lacks a strict and uniform international naming standard, so it is difficult to achieve data sharing with this technique. With its convenience, high resolution, reliable data, and easy real-time internet sharing, MLST is widely used (14). In this study, the MLST typing results showed that the 95 Salmonella strains we isolated fell into five ST types (ST92, ST11, ST2151, ST13, and ST47) (1/95, 1.05%). The following correlations between STs and *Salmonella* serovars were founded: ST13 with *S. agona*, ST11 with *S. Enteritidis*, and ST92, ST2151, and ST47 with *S. gallinarum-pullorum*. Among them, ST92 (37/95, 38.95%) was the most common, a finding consistent with the results of a
FIGURE 4 | Carriage of 18 Drug Resistance Genes in the 95 Salmonella Strains. A total of four different drug resistance genes were detected in the DNA from the isolates, including those encoding β-lactams, aminoglycosides, and sulfonamides. The highest detection rate was for blaTEM and sul3 (both were 100%, 95/95), followed by sul2 and aaC4 with detection rates of 52.63 and 23.16%, respectively.

FIGURE 5 | Proportions and Allelic Map of the Five STs in the 95 Salmonella Isolates. (A) MLST classification showed that the 95 Salmonella strains fell into the following five STs: ST92 (37/95, 38.95%), ST11 (22/95, 23.16%), ST2151 (19/95, 20.00%), ST13 (16/95, 16.84%), and ST470 (1/95, 1.05%). (B) Apart from ST13, the other four STs shared close genetic relationships. The genetic direction was found to be ST11-ST470-ST92-ST2151, and ST11 is the core sequence type.

study on S. enteritidis in China from 2011 to 2016 (30), thereby confirming that the current Salmonella type still dominates. In addition to ST13, the Salmonella isolates displayed four other close ST kinships, with the genetic direction being ST11-ST470-ST92-ST2151.

In this study, β-lactams, quinolones, aminoglycosides, tetracyclines, and sulfonamides were tested on the 95 isolates. Among them, β-lactam-, aminoglycoside-, and sulfonamide-resistance genes were detected by PCR. Four resistance genes were detected, among which the detection rate for the β-lactam blaTEM resistance gene and the sul3 sulfonamide resistance gene was 100% (95/95) for both, whereas those of sul2 and aaC4 were 52.63 and 23.16%, respectively. Quinolone resistance genes and tetracycline resistance genes were not detected. This result is consistent with the results of a study (31) on sulfonamide-resistance genes in Pasteurella multocida, where the detection rate for sul2 (and sul1) exceeded 97%. Furthermore, Zhu et al. (32) identified sulfonamide-resistance genes (sul1, sul2, and sul3) in 89 (97.8%) Salmonella isolates. These findings indicate that sulfonamide-resistance genes are relatively stable in the environment. Extended-spectrum β-lactamase (ESBL)-producing Salmonella is a significant
clinical and food safety concern worldwide (33). *Salmonella* isolates that harbor ESBL-encoding genes are able to hydrolyze penicillin as well as most of the first, second, and third generation cephalosporins, and even carbapenems (34, 35). In the present study, all the *Salmonella* isolates carried *bla*<sub>TEM</sub>, a β-lactam resistance gene, highlighting their potential pathogenesis and the risk posed by this pathogen to Chinese poultry breeding farms.

The Chinese Veterinary Pharmacopeia report (30) pointed out that the drugs tested in the present study, including EM, TE, SXT, and AM, have been widely used in poultry production in China. The resistance rate of these 95 isolates to AM, STR, TE, and EM ranged from 53.68 to 100%. The *Salmonella* isolates from each province in this article were resistant to at least three common antibacterial drugs, and the proportion of MDR strains was 70.53% (67/95), which is consistent with the results from previous surveys (15, 36). This result is consistent with the findings of previous reports from Iran and the United States (37, 38). It is worth noting that should strains with the same MDR genotypes as those identified in the *Salmonella* isolates be transferred to humans via chickens and their derivatives and with different degrees of resistance to 14 antibacterial drugs as was shown for our isolates, this would constitute a major public health threat.

A recent study indicated that integrons and multiple drug resistance genes on mobile plasmids may be responsible for the stable spread of MDR genes in *Salmonella* (39). Previous studies on class I integrants in *Salmonella* in Hubei, Shandong, and Shanxi (18, 39, 40) provinces have found that class I integrants displaying the various antibiotic resistance gene cassettes that are commonly found in *Salmonella* isolates are associated with provinces, markets, and storage conditions differ. Multiple antibiotic resistance in isolates carrying class I integrons is significantly higher than that seen in isolates lacking these integrons, and they usually show a corresponding antibiotic resistance spectrum to the antibiotic resistance gene cassette contained in their class I integrants. In the present study, the detection rate for class I integrants was 0 (0/95), and the influence of gene mutations and other factors relating to drug resistance in *Salmonella* was not investigated. This may be related to the stricter control measures of breeding poultry farms compared to commercial chicken farms, bacterial infectious diseases are better controlled, and the application of antibiotics is greatly reduced. At the same time, it should be noted that poultry farming often uses antibiotics, which may explain the resistance patterns we observed with the tested antibiotics. Therefore, reducing antibiotic use is particularly important for limiting the emergence of super multidrug resistant organisms so that good health in humans and animals can be maintained.

**CONCLUSIONS**

The *Salmonella* detection rate for the 17 breeder farms in the Chinese provinces we surveyed was 3.59%. Five STs, ST92, ST11, ST2151, ST13, and ST470 were identified. Our results indicate that among the *Salmonella* prevalent in the poultry breeder farms in the various provinces, *S. gallinarum*, *S. enteritidis*, and *S. agona* still occupy the main positions. All of the *Salmonella* isolates carried *bla*<sub>TEM</sub> and sul2, and 64.21% were MDR strains, suggesting that antibiotic use in the poultry breeder farms still requires attention. The correlation between the serotypes and the molecular subtypes of the *Salmonella* isolates suggests that the results of a comprehensive analysis of different methods may provide more useful epidemiological information related to this infection. Our findings will update current knowledge on the prevalence of antibiotic resistance on poultry breeding poultry farms in China and provide information and technical support toward the long-term goal of eradicating salmonellosis.

**DATA AVAILABILITY STATEMENT**

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

**AUTHOR CONTRIBUTIONS**

SS, FW, and XG conceived and designed the experiments and analyzed the data. YanS, FZ, LZ, and FW performed the experiments and contributed the reagents. YL performed data validation. FW and YanyS wrote the manuscript. All authors have read and approved the final manuscript.

**FUNDING**

This work was supported by the Fund of Shandong Agricultural Major Application Technology Innovation (SD2019XM009), the Key Research and Development Program of Shandong Province (Important Science and Technology Innovation Project, 2019JZZY010735), Collaborative Innovation Program of Shandong Higher Education Institutions (SDE [2017] 11), and the Funds of Shandong Double Tops Program (SYL2017YSTD11). These funding bodies played no role in the design of the study and collection, analysis, and interpretation of data and in writing the manuscript.
