Abstract

We calculate the decay width and the $\tau$-lepton energy distribution as well as relevant moments for inclusive $\bar{B} \to X_c \tau \bar{\nu}_\tau$ process including power corrections up to order $\Lambda_{QCD}^3/m_b^3$ and QCD corrections to the partonic level. We compare the result with the sum of the standard-model predictions of the branching fractions of the exclusive semileptonic $\bar{B} \to (D, D^*, D^{**}) \tau \bar{\nu}_\tau$ decays as well as with the relevant experimental data. Our prediction is in agreement with the LEP measurement and is consistent with the standard-model calculation of the exclusive modes. We discuss the impact from physics beyond the Standard Model.

Keywords: Heavy quark physics; Heavy quark expansion; Inclusive decays
1 Introduction

Semi-tauonic $B$ decays have attracted renewed attention after the measurements of the exclusive channels $\bar{B} \to D^{(*)} \tau \bar{\nu}$, which exhibit a tension with the Standard Model (SM) [1, 2, 3, 4]. In fact, the theoretical predictions within the SM turn out to be quite precise, since one of the relevant form factors can be inferred from the decays into light leptons (electrons and muons), while the longitudinal form factor that appears only for the heavy $\tau$ lepton can be related to the known one by heavy quark symmetries (HQS). Although the use of HQS implies corrections of the order $\Lambda_{QCD}/m_c$, a good precision is maintained due to the fact, that the contribution of the longitudinal form factor receives an additional suppression factor $m_\tau^2/m_B^2$.

However, there is another problem with the current data on exclusive semi-tauonic $B$ decays which is related to the degree of saturation of the inclusive $\bar{B} \to X_c \tau \bar{\nu}$ rate. There is on the one hand a measurement of this inclusive rate based on the $b$-hadron admixture as it was generated by LEP [5],

$$\text{Br}(b\text{-admix} \to X\tau\bar{\nu}) = (2.41 \pm 0.23)\%$$

which to leading order in the heavy quark expansion (HQE) should be the branching ratio for each individual hadron. On the other hand, one may also compute the inclusive semi-tauonic ratio $R(X_c) = \Gamma(\bar{B} \to X_c\tau\bar{\nu})/\Gamma(\bar{B} \to X_c\ell\bar{\nu})$, where $\ell$ is a light lepton. This ratio does not depend on $V_{cb}$ and can been computed within the HQE very precisely. In combination with the accurately measured branching ratio $\text{Br}(\bar{B} \to X_c\ell\bar{\nu})$ one finds in the $1S$ scheme including corrections up to $1/m_b^2$ [7]

$$\text{Br}(B^- \to X_c\tau\bar{\nu}) = (2.42 \pm 0.05)\%$$

in full agreement with the LEP measurement. Taking the current data for $R(D)$ and $R(D^*)$ at face value, the two exclusive decay modes $\bar{B} \to D\tau\bar{\nu}$ and $\bar{B} \to D^*\tau\bar{\nu}$ would at least fully saturate (if not oversaturate) the inclusive rate.

This situation has motivated us to perform an independent calculation of $\bar{B} \to X_c\tau\bar{\nu}$ within the HQE. The calculation presented in [6] makes use of the $1S$ scheme and includes terms up to order $1/m_b^2$. In this paper we present a calculation in the kinetic scheme and include terms up to order $1/m_b^3$, improving the existing calculations by including the next order in the HQE. In the light of the quite precise prediction for the inclusive $\bar{B} \to X_c\tau\bar{\nu}$ rate we discuss the theoretical predictions for the exclusive channels $\bar{B} \to D^{(*)\tau\bar{\nu}}$ and compare to the current experimental situation.

2 The Inclusive $\bar{B} \to X_c\tau\bar{\nu}$ Decay

2.1 Outline of the Calculation

The matrix element for the $\bar{B} \to X_c\ell\bar{\nu}$ ($\ell = e, \mu, \tau$) decay can be written in terms of the low energy effective Hamiltonian for the weak process $b \to c\ell\bar{\nu}$:

$$\mathcal{H}_W = \frac{G_F V_{cb}}{\sqrt{2}} J_L^\alpha J_H^\alpha + h.c.,$$

where $J_L^\alpha = \bar{\ell}\gamma^\alpha(1 - \gamma^5)\nu$ and $J_H^\alpha = \bar{c}\gamma^\alpha(1 - \gamma^5)b$ are the leptonic and hadronic currents, respectively, and $V_{cb}$ is the CKM matrix element involved in the decay.
We express the triple-differential distribution for $\bar{B} \rightarrow X_c \ell \bar{\nu}$ in terms of the energies of the lepton and neutrino $E_\ell$ and $E_\nu$ and the dilepton invariant mass $q^2 = (p_\ell + p_\nu)^2$ as
\[
\frac{d\Gamma}{dE_\ell dq^2 dE_\nu} = \frac{G_F^2 |V_{cb}|^2}{16\pi^3} L_{\alpha\beta} W^{\alpha\beta}, \tag{2.2}
\]
where $L_{\alpha\beta}$ and $W_{\alpha\beta}$ are called the leptonic and hadronic tensors, respectively. In the Standard Model, the leptonic tensor takes the form
\[
L^{\alpha\beta} = \sum_{\text{lepton spin}} \langle 0| J_L^{\alpha\beta}|\ell \bar{\nu}\rangle \langle \ell \bar{\nu}| J_L^{\alpha\beta}|0\rangle = 8(p_\ell^\alpha p_\nu^\beta + p_\ell^\beta p_\nu^\alpha - g^{\alpha\beta}(p_\ell \cdot p_\nu) - i\varepsilon^{\alpha\beta\gamma\delta} p_\ell^\gamma p_\nu^\delta) \tag{2.3}
\]
and the hadronic tensor is defined as
\[
W^{\alpha\beta} = \frac{1}{4} \sum_{X_c} \frac{1}{2m_B} (2\pi)^3 \langle \bar{B}| J_{H}^{\alpha\beta}|X_c\rangle \langle X_c| J_{H}^{\beta\alpha}|\bar{B}\rangle \delta(4)(p_B - q - p_{X_c}). \tag{2.4}
\]
Its general decomposition into scalar functions $W_j = W_j((v \cdot q), q^2), j = 1, \ldots, 5$ reads
\[
W^{\alpha\beta} = -g^{\alpha\beta} W_1 + v^\alpha v^\beta W_2 - i\varepsilon^{\alpha\beta\rho\sigma} v_\rho q_\sigma W_3 + q^\alpha q^\beta W_4 + (q^\alpha v^\beta + q^\beta v^\alpha) W_5. \tag{2.5}
\]
After contraction of leptonic and hadronic tensors the triple differential decay rate takes the form:
\[
\frac{d\Gamma}{dE_\ell dq^2 dE_\nu} = \frac{G_F^2 |V_{cb}|^2}{2\pi^3} \left\{ q^2 W_1 + \left(2E_\ell E_\nu - \frac{q^2}{2}\right) W_2 + q^2 (E_\ell - E_\nu) W_3 \right. \tag{2.6}
\]
\[
+ \left. \frac{1}{2} m_\ell^2 \left[ -2 W_1 + W_2 - 2 (E_\ell + E_\nu) W_3 + q^2 W_4 + 4E_\ell W_5 \right] - \frac{1}{2} m_\ell^4 W_4 \right\}.
\]
Due to the optical theorem, the hadronic tensor $W^{\alpha\beta}$ is related to the discontinuity of a time-ordered product of currents:
\[
T^{\alpha\beta} = -\frac{i}{4} \int d^4x e^{-iqx} \frac{\langle \bar{B}| T \left\{ J_{H}^{\alpha}(x) J_{H}^{\beta}(0) \right\} |\bar{B}\rangle}{2m_B} \tag{2.7}
\]
via the relations
\[
-\frac{1}{\pi} \text{Im} T_j = W_j \tag{2.8}
\]
with the structure functions $T_i$ defined in analogy to $W^{\alpha\beta}$:
\[
T^{\alpha\beta} = -g^{\alpha\beta} T_1 + v^\alpha v^\beta T_2 - i\varepsilon^{\alpha\beta\rho\sigma} v_\rho q_\sigma T_3 + q^\alpha q^\beta T_4 + (q^\alpha v^\beta + q^\beta v^\alpha) T_5. \tag{2.9}
\]
Inserting $p_\ell = m_\ell v + k$ for the momentum of the $b$ quark and expanding in the residual momentum $k \sim \mathcal{O}(\Lambda_{\text{QCD}})$ yields the standard OPE as it is used for the light leptons. A simple way to derive this OPE at tree level based on an external-field method has been derived in [\ref{8}].

In order to calculate $\tau$-lepton energy spectrum and decay width we need to define the kinematic boundaries of the variable involved in the triple differential decay rate (2.6). We introduce the following dimensionless variables
\[
\hat{q}^2 = \frac{q^2}{m_\ell^2}, \quad x = \frac{2E_\nu}{m_\ell}, \quad y = \frac{2E_\tau}{m_\ell} \tag{2.10}
\]
and the mass parameters
\[ \rho = \frac{m_c^2}{m_b^2}, \quad \eta = \frac{m_{\tau}^2}{m_b^2} \]  
(2.11)

We first perform an integration over the energy of the final state neutrino \( E_\nu \) and in terms of corresponding dimensionless variable \( x \) the limits of integration are determined as
\[ \frac{\hat{q}^2 - \eta}{y_+} \leq x \leq \frac{\hat{q}^2 - \eta}{y_-}, \quad y_{\pm} = \frac{1}{2} \left( y \pm \sqrt{y^2 - 4\eta} \right). \]  
(2.12)

Subsequently we perform the integration over variable \( \hat{q}^2 \) with corresponding boundaries:
\[ y_- \left( 1 - \frac{\rho}{1 - y_-} \right) \leq \hat{q}^2 \leq y_+ \left( 1 - \frac{\rho}{1 - y_+} \right), \]  
(2.13)

and one gets the \( \tau \)-lepton energy distribution. Integration over all possible values of the \( \tau \)-lepton energy
\[ 2\sqrt{\eta} \leq y \leq 1 + \eta - \rho \]  
(2.14)

allows us to calculate decay width.

In this way we obtain the analytic result for the decay width which can be presented in the following form:
\[ \Gamma(B \to X_c \tau \bar{\nu}) = \Gamma_0 \left( 1 + A_{ew} \right) \left[ C_0^{(0)} + \frac{\alpha_s}{\pi} C_0^{(1)} + C_{\rho_c^2} \frac{\mu_{\tau}^2}{m_b^2} + C_{\rho_c^3} \frac{\mu_{\tau}^2}{m_b^2} + C_{\rho_s^3} \frac{\rho_{D}^3}{m_b^3} + C_{\rho_{Ls}^3} \frac{\rho_{Ls}^3}{m_b^3} \right], \]  
(2.15)

where nonperturbative parameters \( \mu_{\tau}^2, \mu_{\tau}^2, \rho_{D}^3, \rho_{Ls}^3 \) are defined as:
\[ 2m_B \mu_{\tau}^2 = -\langle B(p)|\bar{b}_v(iD)b_v|B(p)\rangle, \]  
(2.16)
\[ 2m_B \mu_{\tau}^2 = \langle B(p)|\bar{b}_v(iD\mu)(iD\nu)(-i\sigma^{\mu\nu})b_v|B(p)\rangle, \]  
(2.17)
\[ 2m_B \rho_{D}^3 = \langle B(p)|\bar{b}_v(iD\mu)(iD\nu)|B(p)\rangle, \]  
(2.18)
\[ 2m_B \rho_{Ls}^3 = \langle B(p)|\bar{b}_v(iD\mu)(iD\nu)(-i\sigma^{\mu\nu})b_v|B(p)\rangle. \]  
(2.19)

Note that this corresponds to a “covariant” definition of these parameters using the full covariant derivatives instead of only their spatial components, for a more detailed discussion see [5].

The coefficients \( C^{(0)}_0, C^{(1)}_0, C_{\rho_c^2}, C_{\rho_c^3}, C_{\rho_s^3}, C_{\rho_{Ls}^3} \) depend on \( \rho \) and \( \eta \), and we define
\[ \Gamma_0 = \frac{G_F^2 |V_{tb}|^2 m_b^5}{192\pi^3}. \]  
(2.20)

The calculation of the decay width revealed that - as in the case of a massless lepton - the corresponding coefficients \( C_{\rho_{Ls}^3} \) for massive \( \tau \)-lepton also vanishes, \( C_{\rho_{Ls}^3} = 0 \). The explicit analytic expressions for coefficients \( C^{(0)}_0, C_{\rho_c^2}, C_{\rho_c^3}, C_{\rho_s^3} \) as functions of \( \rho \) and \( \eta \) can be found in Appendix. The derived expressions for \( C^{(0)}_0, C_{\rho_c^2} \) and \( C_{\rho_c^3} \) are in agreement with the corresponding results of [9] [10], while analytic formula for \( C_{\rho_s^3} \) represents a new result of this paper which in the particular case \( m_t \to 0 \) (or equivalently \( \eta \to 0 \)) reproduces the corresponding expression in [8] originally derived in [11]. Moreover, we include perturbative radiative corrections to the partonic level of the decay width using results of [12]. This correction is presented as \( C^{(1)}_0 \) in
Additionally, we include the electroweak correction $A_{ew}$ to the decay width which is well-known and can be found in [13]:

$$1 + A_{ew} \approx \left(1 + \frac{\alpha_{em}}{\pi} \ln \frac{M_Z}{m_b}\right)^2 \approx 1.014.$$  \hspace{1cm} (2.21)

Moreover, we calculate the $\tau$-lepton energy distribution and their moments. We define the moments of the $\tau$-lepton energy distribution as in [14]

$$M^n_\tau \equiv \langle E^n_\tau \rangle_{E_\tau > E_{cut}} = \frac{\int_{E_{cut}}^{E_{max}} dE_\tau E^n_\tau \frac{d\Gamma}{dE_\tau}}{\int_{E_{cut}}^{E_{max}} dE_\tau \frac{d\Gamma}{dE_\tau}}$$  \hspace{1cm} (2.22)

and the central moments

$$\overline{M^n_\tau} \equiv \langle (E_\tau - \langle E_\tau \rangle)^n \rangle_{E_\tau > E_{cut}},$$  \hspace{1cm} (2.23)

where $E_{cut}$ denotes the energy cut of $\tau$-lepton and $E_{max}$ is its maximal value.

### 2.2 Numerical analysis and results

| Parameter | Value \( \pm \) | Units | Source |
|-----------|----------------|-------|--------|
| $m^\text{kin}_b$ | 4.561 \pm 0.020 | GeV | |
| $m^\text{kin}_c$ | 1.092 \pm 0.020 | GeV | |
| $\mu^2_\pi$ | 0.464 \pm 0.067 | GeV$^2$ | |
| $\mu^2_G$ | 0.333 \pm 0.061 | GeV$^2$ | |
| $\rho^3_D$ | 0.175 \pm 0.040 | GeV$^3$ | [17] |
| $\rho^3_L$ | -0.146 \pm 0.096 | GeV$^3$ | |
| $V_{cb} \times 10^{-3}$ | 42.04 \pm 0.67 | | |
| $\alpha_s$ | 0.218 \pm 0.018 | | |
| $G_F$ | \(1.16637 \times 10^{-5}\) | GeV$^{-2}$ | |
| $m_\tau$ | 1.777 | GeV | [5] |
| $\tau_{B^+}$ | 1.638 | ps | |
| $\tau_{B^0}$ | 1.520 | ps | |

Table 1: The values of the parameters involved in the decay width given in kinetic scheme. The corresponding matrix of the correlations between the parameters can be found in [17].

We evaluate the rate and the moments in the kinetic scheme. To this end, we re-write the pole mass in (2.15) in terms of the kinetic mass, using the one loop relation from [15]

$$m^\text{pole}_Q = m^\text{kin}_Q(\mu) \left(1 + r_Q(\mu) \frac{\alpha_s}{\pi}\right)$$  \hspace{1cm} (2.24)

with $Q = b$ or $c$ and auxiliary coefficient $r_Q$:

$$r_Q(\mu) = \frac{4}{3} C_F \frac{\mu}{m^\text{kin}_Q(\mu)} \left(1 + \frac{3}{8} \frac{\mu}{m^\text{kin}_Q(\mu)}\right).$$  \hspace{1cm} (2.25)
Inserting (2.24) into (2.15) allows us to absorb parts of the one-loop QCD corrections into the mass definition. In a similar way as for the light lepton, the remaining corrections are small and thus allow us a precise prediction.

The numerical values of the parameters used in our analysis are given in Tab. 1. For a simple comparison to the massless case we show the dependence of the coefficients $C_0, C_{\mu_2^2}, C_{\mu_G^2}, C_{\rho_D^3}$ in the kinetic scheme on the mass of the $\tau$ lepton in Fig. 1.

Tab. 2 shows a breakdown of the various contributions for the total branching fraction, where we use the PDG values for the lifetimes. We can now compute the total rate, and with the input of the measured lifetime we get for the branching fraction of the inclusive $B^+ \rightarrow X_c \tau^+ \nu_\tau$ decay

$$\text{Br}(B^+ \rightarrow X_c \tau^+ \nu_\tau) = (2.37 \pm 0.08)\%,$$

where the uncertainty appears due to a variation of the input parameters within their intervals including the correlations between them. The corresponding matrix of correlations between parameters shown in Tab. 1 is not presented here and can be found in [17]. The uncertainty in (2.26) includes also an estimate of the higher power contribution of order $O(\Lambda_{\text{QCD}}^4/m_b^4)$ where the relevant coefficient is conservatively assumed to be of order one. Moreover, we include the estimate of the contributions of the higher order radiative corrections. We note that the corrections of order $O(\alpha_s^2)$ have been computed in the on-shell scheme in [16] and were found to be small. Thus we assume that the impact of the $O(\alpha_s^2)$ corrections in the kinetic scheme is
Table 2: Values of the branching fraction of the inclusive $B^+ \rightarrow X_c^+ \tau^+ \nu_\tau$ decay depending on the different kinds of perturbative and power corrections included there. The last row represents our final prediction for this process. Here the following value of charged $B$-meson life time $\tau_B^+ = 1.638$ ps is used [5]. In order to get results for neutral mode $B^0 \rightarrow X_c^- \tau^+ \nu_\tau$ it is sufficient to multiply values given in table by factor $\tau_B^0 / \tau_B^+ \approx 0.928$ [5].

within the quoted in (2.26) uncertainties.

Alternatively, we can compute the ratio $R(X_c) = \frac{\text{Br}(B^+ \rightarrow X_c \tau^+ \nu_\tau)}{\text{Br}(B^+ \rightarrow X_c \ell^+ \nu_\ell)}$ for which we obtain

$$R(X_c) = 0.212 \pm 0.003.$$  

(2.27)

Combining this with the recent world average, $\text{Br}(B \rightarrow X_c \ell \nu_\ell) = (10.65 \pm 0.16)\%$, quoted by HFAG [23], we can avoid the uncertainty in $V_{cb}$, and we thus find an even more precise prediction

$$\text{Br}(B^+ \rightarrow X_c \tau^+ \nu_\tau) = (2.26 \pm 0.05)\%,$$  

(2.28)

with a slightly smaller central value compared to (2.26), which is, however, within the 1σ range. We note that the uncertainty of our result (2.28) is comparable with one in [7]. However, our analysis shows that the coefficient in front of $\rho_D^3$ is of the order of ten, similar to what is observed for the case of a massless lepton. The result of including the $1/m_b^3$ corrections is thus a significant shift of the central value compared to the analysis up to $1/m_b^2$ as the one presented in [7], see also Tab. 2.

Our predictions are also consistent with the measurement of the inclusive branching fraction of the LEP admixture of bottom baryons [5]

$$\text{Br}(b\text{-admix} \rightarrow X \tau^\pm \nu) = (2.41 \pm 0.23)\%.$$  

(2.29)

Moreover, we also show the resulting $\tau$-lepton energy distribution in Fig. 2. However, these curves cannot be interpreted on a point-by-point basis, since the OPE breaks down in the endpoint region. Note that this region is in fact larger than in the case of massless leptons due to the sizeable mass of the $\tau$ lepton. However, moments of these spectra can be interpreted in the $1/m_b$ expansion.

In [6] the authors also derived standard model predictions for the $\tau$ energy distribution as well as dilepton invariant mass spectrum in the inclusive $B \rightarrow X_c \tau \bar{\nu}$ decay including $\Lambda_{QCD}^3/m_b^2$ and $\alpha_s$ corrections in the 1S mass scheme. In additions, they estimated the effects from shape functions in the endpoint region. In our paper we focus on the $\tau$ energy distribution, including the $\Lambda_{QCD}^3/m_b^3$ corrections. In our analysis we use the kinetic scheme which explains some visible differences between the shapes of the curves presented in Fig. 2 of our paper and in Fig. 2 of [6].
Figure 2: $\tau$-lepton energy spectrum of the inclusive $\bar{B} \to X_c \tau \bar{\nu}_\tau$ decay.

![Energy Spectrum Diagram](diagram.png)

Table 3: The values of the moments of the $\tau$-lepton energy distribution for three different values of the cutoff energy $E_{\text{cut}}$.

| Moment          | $E_{\text{cut}} = 1.8$ GeV | $E_{\text{cut}} = 2.0$ GeV | $E_{\text{cut}} = 2.2$ GeV |
|-----------------|----------------------------|----------------------------|----------------------------|
| $M_1^2$ [GeV]   | $2.118 \pm 0.006$          | $2.197 \pm 0.007$          | $2.321 \pm 0.015$          |
| $M_2^2$ [GeV^2] | $0.028 \pm 0.003$          | $0.015 \pm 0.003$          | $0.004 \pm 0.004$          |
| $10^3 \times M_3^2$ [GeV^3] | $0.08 \pm 1.21$          | $-0.12 \pm 1.02$          | $-1.24 \pm 0.82$          |

In the case of the light leptons the lepton energy distribution and the relevant moments are the measurable observables. However, for $\tau$ leptons, these observables will be more difficult to access, since the $\tau$ has to be reconstructed from its decay products. Nevertheless, it is instructive to show the $\tau$-lepton energy moments defined by eqs. (2.22) and (2.23) as a function of the cutoff energy $E_{\text{cut}}$ for the sake of comparison with the light lepton case. We present our results in Fig. 3 and give the numerical results for several values of $E_{\text{cut}}$ in Tab. 3. Once abundant data on this decay becomes available, appropriate inclusive observables have to be defined, which should take into account the decay of the $\tau$ lepton. The construction of such observables will be subject of future work.

3 The exclusive $\bar{B} \to D^{(*,**)} \tau \bar{\nu}$ decays

Finally, we compare the inclusive result to the sum of identified exclusive states. The decays $\bar{B} \to D^{(*)} \tau \bar{\nu}$ into the two ground-state mesons $D$ and $D^*$ are described in terms of six form factors, some of which can be accessed in the corresponding decays into light leptons. However, due to the sizeable mass of the $\tau$ lepton there are two form factors which cannot be accessed from light-lepton data. For these one may make use of heavy quark symmetries to get at least an estimate. Still a quite precise prediction can be made due to the fact that the contribution of these form factors come with a suppression factor $m_\tau^2/m_B^2$. Also the decays into the first orbitally excited mesons have been studied in the heavy mass limit. Using QCD sum rules for the form factors appearing in these processes one may get an estimate for these decays, which we shall generically denote as $\bar{B} \to D^{**} \tau \bar{\nu}$.

In Tab. 4 we quote the recent SM predictions for these processes, referring to [18] for exclusive $\bar{B} \to D \tau \bar{\nu}$ and $\bar{B} \to D^* \tau \bar{\nu}$ decays and to [19] and [20] for $\bar{B} \to D^{(**)} \tau \bar{\nu}$. We note that
Figure 3: Dependence of the moments of $\tau$-lepton energy spectrum on the value of the cutoff energy $E_{\text{cut}}$. The left plot corresponds to the first moment $M_1^\tau(E_{\text{cut}})$, the middle plot contains the second central moment $\overline{M}_2^\tau(E_{\text{cut}})$, the right plot contains the third central moment $\overline{M}_3^\tau(E_{\text{cut}})$. The solid curves with green shaded areas indicating uncertainties are the result of the full calculation, the dashed ones are without $1/m_\tau^3$ corrections.

the SM predictions for the exclusive channels $B^+ \rightarrow D^{(*)0}\tau^+\nu_{\tau}$ imply

$$\text{Br}(B^+ \rightarrow D^0\tau^+\nu_{\tau}) + \text{Br}(B^+ \rightarrow D^{*0}\tau^+\nu_{\tau}) + \sum_{D^{**}} \text{Br}(B^+ \rightarrow D^{**0}\tau^+\nu_{\tau}) = (2.14 \pm 0.16)\%.$$ (3.1)

It is important to mention the recent paper [21] where the most precise prediction for $R(D) = 0.299 \pm 0.003$ was derived based on the combination of the experimental data and the result of the lattice calculation of the both $B \rightarrow D$ scalar and vector form factors [22]. However, in our paper we focus on the calculation of the branching fraction of the inclusive decay and on the comparison with the corresponding branching fractions of the exclusive modes, and at this level the value given in eq. (3.1) is sufficient for our purpose. From (3.1) one can see that the decays into the two ground state $D$ mesons already saturate the predicted inclusive rate to about 85%, the lowest orbitally excited states add another 6%, leading to a saturation of the predicted inclusive rate at a level of 90%. This is in agreement with the expectation from the decays into light leptons, where the measured decay rates to the two ground state $D$ mesons saturate the measured inclusive rate at a level of about 72%. Note that due to the sizeable $\tau$ lepton mass we expect a lesser degree of saturation for the light leptons, so the overall picture is very consistent.

In Tab. [4] we also show the recent experimental data on $\bar{B} \rightarrow D\tau\bar{\nu}$ and $\bar{B} \rightarrow D^*\tau\bar{\nu}$. We use the HFAG values for $R(D)$ and $R(D^*)$ and combine them with the PDG values for the branching ratios with light leptons to get the branching ratios for the semitauonic decays.
Summing the experimental values for branching ratios into the two ground state $D$ mesons, we find an indication that these two decays alone already over-saturate the predicted inclusive rate, however, only at a level of $2\sigma$. We take this as an indication of an inconsistency, which needs to be clarified.

| Mode  | Theory (SM) | Experiment (HFAG + PDG) |
|-------|-------------|-------------------------|
| $\text{Br}(B^+ \to D^0\tau^+\nu_\tau)$ | (0.75 ± 0.13) % | (0.91 ± 0.11) % |
| $\text{Br}(B^+ \to D^{*0}\tau^+\nu_\tau)$ | (1.25 ± 0.09) % | (1.77 ± 0.11) % |
| $\text{Br}(B^+ \to (D^0 + D^{*0})\tau^+\nu_\tau)$ | (2.00 ± 0.16) % | (2.68 ± 0.16) % |
| $\sum_{D^{**}} \text{Br}(B^+ \to D^{**0}\tau^+\nu_\tau)$ | (0.14 ± 0.03) % | — |

Table 4: SM predictions and experimental results concerning the branching fraction of $B^+ \to D^{(*)0}\tau^+\nu_\tau$ decays. In the second column the SM predictions of [18] and [20] are presented and in the third column the values extracted from combined data provided by HFAG [23] and PDG [5] are given.

4 Discussion and Conclusions

The tension of the recent data for $R(D)$ and $R(D^*)$ with the theoretical predictions for these exclusive channels has been intensively discussed recently, including a possible explanation through effects from “New Physics” (NP). However, as it has been noticed before, there is also information on the inclusive rate, experimental as well as theoretical.

On the theoretical side, the heavy quark expansion allows us to perform a precise calculation of the inclusive semitauonic decay rates as well as of spectral moments. In the present paper we performed this calculation up to and including term at order $1/m_b^3$, thereby improving the existing calculations by one order in the $1/m_b$ expansion. On the experimental side we have a measurement of the inclusive rate from LEP which, however, is not precise enough to allow for a stringent test.

There have been various attempts to explain the tension in $R(D)$ and $R(D^*)$ in terms of different NP scenarios. We do not go into a detailed discussion of all possible scenarios, we rather parametrize the effects of NP by a simple extension of the effective Hamiltonian

$$\mathcal{H}_{NP} = \frac{G_F V_{cb}}{\sqrt{2}} (\alpha O_{V+A} + \beta O_{S-P})$$

with the new operators

$$O_{V+A} = \bar{c}\gamma_\mu(1 + \gamma_5)b \left(\bar{\tau}\gamma^\mu(1 - \gamma_5)\nu_\tau\right),$$
$$O_{S-P} = \bar{c}(1 - \gamma_5)b \left(\bar{\tau}(1 - \gamma_5)\nu_\tau\right)$$

and the dimensionless couplings $\alpha$ and $\beta$. Our main motivation is to study the effect of (4.1) on the inclusive rate on the basis of this example.

We may discuss this effective low-energy interaction in the context of a standard-model effective theory (SMEFT) with linear realization of the Higgs field. It is interesting to note
that the above operator structures cannot be obtained at the leading order of the SMEFT expansion, since we insist on having lepton-universality violation. At dimension 6 we can write

$$P \gamma \nu_j b_R = (\bar{c}_R \gamma \mu b_R) \left( \phi^\dagger (i D^\mu) \phi \right)$$

(4.3)

where $\phi$ is the SM Higgs doublet field. After spontaneous symmetry breaking, this operator generates an anomalous coupling of the $W$ to the right handed $b \to c$ current. Since the SM coupling to the $W$ is lepton universal, the insertion of this operator into the SM Lagrangian would lead to a lepton-universal effect. Thus we would need to combine this with another new-physics operator which will have dimension six and which generates a lepton-universality violating coupling of the $W$ to the left handed $\tau \to \nu$ current. Upon integrating out the $W$ boson, the combination of the two dimension-six operators generates the same effects as the dimension eight operators we shall discuss now. In fact, writing the left-handed $SU(2)_L$ doublets as $L$ for the leptons and $Q$ for the quarks, we can construct the relevant $SU(2)_L \times U(1)_Y$ invariant operators of dimension eight

$$O'_{V+A} = (\bar{c}_R \phi^\dagger Q) \left( \bar{\phi}^\dagger L \right),$$

(4.4)

$$O'_{S-P} = (\bar{c}_R \phi^\dagger Q) \left( \bar{\phi}^\dagger L \right),$$

(4.5)

where $\phi$ is the charge conjugate Higgs field. Once the Higgs field acquires its VEV $\langle \phi \rangle = \frac{v}{\sqrt{2}}$ and $\langle \bar{\phi} \rangle = \frac{v}{\sqrt{2}}$, we obtain $8 O'_{V+A} = v^2 O_{V+A}$ and $8 O'_{S-P} = v^2 O_{S-P}$. To this end, we infer that within the SMEFT power counting we have

$$\alpha, \beta = O \left( \frac{v^4}{\Lambda_{NP}^2 V_{cb}} \right).$$

(4.6)

However, the purpose of our simple ansatz (4.1) is not a sophisticated analysis of NP effects, rather we want to study the effect of NP on the inclusive rate. It is a straightforward exercise to add (4.1) to the effective Hamiltonian of the SM and to re-compute the exclusive decay rates for $B_{NP}(\bar{B} \to D^{(*)} \ell \nu_\ell)$ including the NP effects, using the heavy-quark limit for the form factors (see eg. [18]). Assuming that there is no effect in the decays into light leptons, the resulting expressions for $R(D)$ and $R(D^*)$ are quadratic forms in the parameters $\alpha$ and $\beta$. We define the corresponding NP ratios $R_{NP}(D^{(*)})$ by

$$R_{NP}(D^{(*)}) = \frac{Br_{NP}(\bar{B} \to D^{(*)} \tau \nu_\tau)}{Br(\bar{B} \to D^{(*)} \ell \nu_\ell)}.$$  

(4.7)

The values of parameters $\alpha$ and $\beta$ are extracted by requiring consistency with the corresponding experimental data on $R(D)$ and $R(D^*)$. Our ansatz is designed to describe both $R(D)$ and $R(D^*)$ simultaneously, and a fit yields

$$\alpha = -0.15 \pm 0.04, \quad \beta = 0.35 \pm 0.08$$  

(4.8)

for the parameters $\alpha$ and $\beta$. Note that there is a second solution, which exhibits destructive interference with the SM contribution. This solution yields a smaller (in comparison with the
Figure 4: Contour plot for the branching fraction of $B^+ \to X_c \tau^+ \nu_\tau$ ([4.9]) as function of $\alpha$ and $\beta$. The green dot together with the ellipse indicate the best fit value and one-sigma range of the parameters $\alpha$ and $\beta$ extracted from $R(D)$ and $R(D^*)$, see ([4.8]). The shaded bands indicate the one-sigma intervals of $\text{Br}(B^+ \to X_c \tau^+ \nu_\tau)$: the red band is our SM prediction ([2.26]), the green area represents the LEP measurement ([2.29]), and the blue band is our prediction for inclusive $B^+ \to X_c \tau^+ \nu_\tau$ decay including contribution from NP (specified in Tab. 5).

It is worthwhile to point out a subtlety in the extraction of the parameters $\alpha$ and $\beta$ from the exclusive decays. The experimental analysis of $R(D)$ and $R(D^*)$ assumes the SM shapes for the kinematic distributions, which are used to extract e.g. efficiencies. However, including the NP operators ([4.2]) will change the shapes of the spectra, and hence the extracted values could shift. As in most other NP analyses we assume that this is only a small effect; a full analysis of this is clearly beyond the scope of this paper.

We are now ready to study the impact of this NP model on the inclusive rate by including the NP operators ([4.2]) into the calculation. Inclusion of NP modifies the parametrization ([2.15]), which becomes

$$\Gamma_{\text{NP}} = \Gamma_{\text{SM}} + \Gamma_0 \left[ A_1 \alpha + A_2 \alpha^2 + C_{12} \alpha \beta + B_1 \beta + B_2 \beta^2 \right],$$

with coefficients $C_0, A_1, A_2, B_1, B_2, C_{12}$ depending on parameters $\rho = m_c^2/m_b^2$ and $\eta = m_\tau^2/m_b^2$, and $\Gamma_{\text{SM}}$ is the expression given in ([2.15]).

In Fig. 4 we show the dependence of the inclusive rate on the parameters $\alpha$ and $\beta$. The green dot together with the ellipse indicate the best fit value and one-sigma range, respectively, of the parameters $\alpha$ and $\beta$ ([4.8]) extracted from $R(D)$ and $R(D^*)$. The shaded bands indicate
Table 5: Summary of predictions for different mode of semitauonic $B$-meson decays in the framework of SM and including NP effects in comparison with relevant experimental data. NP predictions presented here correspond to the first scenario for parameters $\alpha, \beta$ (4.8). We do not quote an uncertainty for the exclusive NP calculations; for fixed $\{\alpha, \beta\}$ the uncertainties are of the same size as the SM ones.

| Decay Mode                                      | SM                  | NP                  | Experiment                      |
|------------------------------------------------|---------------------|---------------------|---------------------------------|
| $\text{Br}(B^+ \rightarrow D^0 \tau^+ \nu_\tau)$ | $(0.75 \pm 0.13)$ % | 0.93 %              | $(0.91 \pm 0.11)$ %             |
| $\text{Br}(B^+ \rightarrow D^{*0} \tau^+ \nu_\tau)$ | $(1.25 \pm 0.09)$ % | 1.65 %              | $(1.77 \pm 0.11)$ %             |
| $\text{Br}(B^+ \rightarrow X_{c\tau^+} \nu_\tau)$ | $(2.37 \pm 0.08)$ % | $(3.15 \pm 0.19)$ % | $(2.41 \pm 0.23)$ %             |

The one-sigma intervals for $\text{Br}(B^+ \rightarrow X_{c\tau^+} \nu_\tau)$: the red band is our SM prediction (2.26), the green area represents the LEP measurement (2.29), and the blue band is our prediction for inclusive $B^+ \rightarrow X_{c\tau^+} \nu_\tau$ decay including the contribution (4.1) from NP (specified in Tab. 5). The error estimate of the latter value contains also the uncertainties from $\alpha$ and $\beta$, including the correlation between them. The NP prediction brings the inclusive rate into agreement with the data on exclusive decays, but is now in visible tension with the LEP data.

Recently, the constraints on NP in the $b \rightarrow c\tau\bar{\nu}$ transition from the tauonic $B_c$ decay have been discussed, however, with a different ansatz for the NP operators [24, 25, 26]. In fact, adding the new physics contribution (4.1) yields a modification of the decay rate $B_c \rightarrow \tau\bar{\nu}$, which reads

$$\Gamma(B_c \rightarrow \tau\bar{\nu}) = \frac{Mm_\tau^2 f_{B_c}^2 G_F^2 |V_{cb}|^2}{8\pi} \left(1 - \frac{m_\tau^2}{M^2}\right)^2 \left[1 - \alpha - \frac{M^2}{m_c(m_b + m_c)} \beta \right]^2,$$

(4.10)

where $M$ is the mass of the $B_c$ meson and $f_{B_c}$ is its decay constant, defined in the usual way. It has been pointed out in [24] that even relatively small values of $\beta$ may have a significant effect in the decay rate, since the pre-factor $M^2/(m_\tau(m_b + m_c)) \sim 4$ enhances the contribution of $O_{S-P}$.

Using the parametrization (4.1) together with our fit values implies a reduction of the tauonic branching fraction for the $B_c$ compared to the SM, since the extracted value of $\beta = 0.35$ is positive and yields in combination with the corresponding pre-factor the relative contribution of order $\sim 1$ but with a opposite sign compared to $(1 - \alpha)$ contribution, as one can see from (4.10). We conclude that the width of leptonic $B_c \rightarrow \tau\bar{\nu}_\tau$ decay including our parametrization of NP is not in tension with the measured $B_c$ lifetime.

Thus we arrive at a different conclusion compared to [24]. However, the reason is that we dropped the assumption that only the leading order in the SMEFT expansion is taken into account. Thus, attributing a possible NP effect leading to the $R(D^{(*)})$ puzzle to dimension-eight operators can lift the constraint obtained in [24]. We have pursued a different purpose with this simple model, but this observation might deserve a more detailed analysis.

5 Appendix

Here the explicit analytic expressions of the coefficients introduced in the $B \rightarrow X_c \tau \nu$ decay width (2.15) as functions of dimensionless variables $\rho$ and $\eta$ are given:

\[ C_0 = \sqrt{R} \left[ 1 - 7\rho - 7\rho^2 + \rho^3 - (7 - 12\rho + 7\rho^2)\eta - 7(1 + \rho)\eta^2 + \eta^3 \right] \]
\[ - 12 \left[ \rho^2 \ln \left( 1 + \rho - \eta - \sqrt{R} \right)^2 + \eta^2 \ln \left( 1 + \eta - \rho + \sqrt{R} \right)^2 - \rho^2 \eta^2 \ln \left( 1 - \rho - \eta - \sqrt{R} \right)^2 \right] \tag{5.1} \]

\[ C_{\rho^2} = \frac{\sqrt{R}}{2} \left[ -3 + 5\rho - 19\rho^2 + 5\rho^3 + (5 + 28\rho - 35\rho^2)\eta - (19 + 35\rho)\eta^2 + 5\eta^3 \right] \]
\[ + 6 \left[ \rho^2 \ln \left( 1 + \rho - \eta - \sqrt{R} \right)^2 + \eta^2 \ln \left( 1 + \eta - \rho + \sqrt{R} \right)^2 - \rho^2 \eta^2 \ln \left( 1 - \rho - \eta - \sqrt{R} \right)^2 \right] \tag{5.2} \]

\[ C_{\rho^3} = \frac{\sqrt{R}}{2} \left[ -3 + 5\rho - 19\rho^2 + 5\rho^3 + (5 + 28\rho - 35\rho^2)\eta - (19 + 35\rho)\eta^2 + 5\eta^3 \right] \]
\[ - 6 \left[ \rho^2 \ln \left( 1 + \rho - \eta - \sqrt{R} \right)^2 + \eta^2 \ln \left( 1 + \eta - \rho + \sqrt{R} \right)^2 - \rho^2 \eta^2 \ln \left( 1 - \rho - \eta - \sqrt{R} \right)^2 \right] \tag{5.3} \]

\[ C_{\rho^3} = \frac{2}{3\rho^2 \sqrt{R}} \left\{ \eta^7 - \eta^6(5\rho + 7) + \eta^5(6\rho^2 + 22\rho + 21) + \eta^4(\rho^3 - 9\rho^2 - 35\rho - 35) \right. \]
\[ + \eta^3(-5\rho^4 - 2\rho^3 - 8\rho^2 + 20\rho + 35) + \eta^2(3\rho^5 - \rho^4 - 4\rho^3 + 18\rho^2 + 5\rho - 21) \]
\[ + \eta(1 - \rho)^3(2\rho^3 + 6\rho^2 + 11\rho + 7) + (\rho - 1)^3(\rho + 1)^2 \]
\[ - R \left[ \eta^5 - \eta^4(3\rho + 5) + \eta^3(-3\rho^2 + 8\rho + 10) + \eta^2(37\rho^3 + 27\rho^2 - 6\rho - 10) \right. \]
\[ + \eta(32\rho^4 - 18\rho^3 - 9\rho^2 + 5) - 4\rho^5 + 10\rho^4 - 3\rho^3 - 15\rho^2 + \rho - 1 \left] \right\} \]
\[ + 8 \left( \eta^2(5\rho^2 + \eta - 1) \ln \left[ \frac{(1 - \rho - \eta - \sqrt{R})^2}{4\eta^2} \right] - (\eta - 1) \ln \left[ \frac{(1 + \rho - \eta + \sqrt{R})^2}{4\rho} \right] \right) \tag{5.4} \]

where $R = \eta^2 - 2\eta(\rho + 1) + (\rho - 1)^2$.
