Abstract
Multiple sclerosis is an inflammatory demyelinating disease that commences to neuronal cell destruction. Recently, a promising evidence of synergic effects of combined supplementation with vitamin D and probiotics in modulating the gut microbiota and metabolome is emerging. *Bacillus Coagulans* IBRC-M10791 as a novel strain was chosen, prevention and treatment impacts of regular administered were studied in Cuprizone-induced C57bl/6 mouse of demyelination. The mice were divided into six groups and received a daily dose of cuprizone or probiotics. To investigate the effect of probiotic, the *IDO-1*, *CYP27B1*, *NLRP1*, *NLRP3*, and *AIM2* expression were estimated by Real-Time PCR, and IL-4, IL-17, IFN-gamma, and TGF-beta cytokines were measured by ELISA. The results showed that there was significant decrease in IL-17 and IFN-γ and modulatory effects on IL-4 and TGF-β. On the other hand, we demonstrated that there are significant decrease for expression of *IDO-1*, *CYP27b1*, *NLRP1*, *NLRP3* and *AIM2* genes in prevention and treatment groups compared to cuprizone group. Also, a significant enhancement in rate of remyelination and alternations proved by LFB staining and Y-Maze test. In conclusion, our study provides insight into how the therapeutic effect of the chosen strain of probiotic was correlated with the modulation of the level of inflammatory and anti-inflammatory cytokines. Further, we demonstrated that the expression of genes related to Tryptophan, Vitamin D and Inflammasome pathways could be affected by *B.coagulans*. Our study could be beneficial to provide a novel Co-therapeutic strategy for Multiple sclerosis.

Introduction
Multiple sclerosis is an autoimmune, inflammatory disease, and one of the most common diseases of the central nervous system that most often occurs in the age range of 20 to 40 years (Abboud et al. 2021). Although the cause of MS remains unknown, several factors such as genetics, environment, vitamin D, and immune system are involved in the occurrence of this disease (Bar-Or et al. 2011), but it is eventually diagnosed with the loss of myelin, nerve damage, and the development of neurological disabilities (Becher et al. 1999).

Various studies on patients with MS indicate that multiple aspects of the innate and adaptive immune systems do not operate correctly in these patients (Beck et al. 1988). In adaptive immune system, excessive increase in invasive activity of Th1 and Th17 by secreting the pro-inflammatory cytokines IFN-γ and IL-17, respectively, plays a crucial role in the immunopathogenesis of MS as well as modulation of anti-inflammatory cytokines such as IL-4 and TGF-β through Th2 and Treg cells (Belkaid and Hand 2014). On the other hand, IFN-γ expression increases transcription of the IDO gene, resulting in decreased T cell activation and proliferation through tryptophan depletion and production of Treg lymphocytes (Benton et al. 2007). Researches have shown that this gene is involved in the pathogenesis of autoimmune diseases, and a change in its expression could indicate the onset of relapse in MS patients (Bermudez-Brito et al. 2012). The role of the innate immune system in MS has
recently received much attention. Inflammasome complex as part of this system detect inflammatory signals generated by infection or endogenous and with increasing the expression of genes such as NLRP1, NLRP3, and AIM2 cause cell maturation and production of IL-1β and IL-18 inflammatory cytokines as well as stimulating the IFN-γ (Cosorich et al. 2017). Previously the gastrointestinal tract was considered the only place to digest and absorb nutrients, while today, several functions such as affecting the body and the nervous system’s general health are recognized (Dargahi et al. 2018). In the gastrointestinal tract, vital bacteria are called intestinal flora that is metabolically active and involved in the production of vitamins and neurotransmitters (Digeysara et al. 2021) and influenced by factors such as age, genetics, race, host nutrition, geography, stressors and they can be changed by taking probiotics (Duhen et al. 2013). Various studies have reported some therapeutic potential of probiotics in reducing the clinical symptoms of many gastrointestinal diseases, improving allergies, and enhancement of the immune system (Eckburg et al. 2005). Numerous studies have also shown that probiotics can reduce inflammation by integrating the barrier of the gastrointestinal tract and reduces the leaking ability of endotoxins into the bloodstream (Gombart 2009). The complex interaction between the host immune system and the normal intestinal flora is essential for maintaining intestinal homeostasis. If dysbiosis happens as a result of changes in the function and type of bacteria, the natural flora can cause spread autoimmune and infectious diseases (Goodin 2016). Recently, a promising evidence of synergic effects of combined supplementation with vitamin D and probiotics in modulating the gut microbiota and metabolome is emerging as well as a correlation between the level of serum vitamin D and MS risk and disease activity. These effects are through improving the expression of vitamin D receptors. Therefore, modulating the microbiota-gut-brain axis by probiotics plus improving vitamin D levels might provide a novel target to treat mental and metabolic disorders (Govindarajan et al. 2020). Vitamin D are hydroxylated by the cytochrome P450 enzyme CYP27A1 in the liver to 25-hydroxyvitamin D (25[OH]D) in substrate-dependent reaction then it circulates in the blood bound to the vitamin D-binding protein and is a reliable indicator of vitamin D status. To become fully activated, the 25[OH] D is converted into 1,25-dihydroxyvitamin D (1,25[OH]2D) by the mitochondrial 1α-hydroxylase enzyme (CYP27B1). The majority of the body’s 1,25(OH)2D is synthesized in the primary renal tubules of the kidney, but synthesis also occurs in numerous extrarenal sites in cells that express CYP27B1 like immune cells especially activated macrophages. Immune activation of macrophages with Toll-like receptor (TLR) ligands or IFN-γ leads to induction of CYP27B1. As circulating levels of 1,25(OH)2D rise, it suppresses its own production via a negative feedback loop in which the VDR binds to the CYP27B1 promoter to repress its expression (He et al. 2019). B.coagulans is a gram-positive, spore-forming, aerobic, and lactic acid-producing bacteria. In comparison to other lactic acid bacteria, due to its protective spore-like protein coating, it can survive against stomach acid, reach the small intestine, grow, and proliferation (Ho et al. 2019). These bacteria produces short-chain fatty acids by secreting coagulin and lactosporin and has antimicrobial activity (Høglund and Maghzachi 2014). Researchers have shown that cell wall components and intracellular fluid are involved in intestinal inflammation by regulating cytokines, inhibiting reactive oxygen species, and increasing phagocytosis (Hughes 2020; Jensen et al. 2010). They reported that intestinal microflora plays a primary role in the mucosal surface immune response by balancing Treg and Th17 (Kelleher et al. 2006). Various mouse models include Experimental autoimmune encephalomyelitis and Cuprizone are widely used to study MS (Kirby TO and Ochoa-Repáraz 2018). The cuprizone model is applied to study demyelination and remyelination in the corpus callosum. Cuprizone induces the death of mature oligodendrocytes, leading to the loss of myelin in the white matter of the brain (Kobayashi et al. 2012). Therefore, this study aimed to survey the effect of B.coagulans on the improvement of demyelinated mice. Consequently, we performed an analysis of IDO gene expression and serum level of IL-17 and TGF-β.

Materials and methods

Animals and demyelination

All methods involving animals and their care were according to the Institutional Animal Care and Use Committee recommendations. The practical protocols used in this study were approved by the local animal ethics committee of the Islamic Azad University Science and Research Branch. The medical intervention and treatment procedures were done according to guidelines. Regarding the statistics criteria, the number of mice was the minimum possible. 42 Female C57BL/6 mice of 7–8 weeks old with weight ranging from 18 to 20 g were obtained from Pasteur Institute, Tehran, Iran. The animals had free access to food and water and were maintained on a 12 h light/dark cycle at room temperature (20–22 °C). According to Zhen et al. (Kobayashi et al. 2012), toxic demyelination was induced by oral administration containing 0.2% (w/w) cuprizone (CPZ).

For oral gavage, CPZ powder was mixed in 0.5% carboxymethyl cellulose (CMC) and use vortex shaker to obtain a homogeneous CPZ–CMC suspension. Mice were fed daily by gavage with10 ml/kg volume. A stock solution of 0.5% CMC was prepared weekly and stored at 4 °C. CPZ and CMC suspension were freshly prepared and consumed daily.
CMC mixture does not react chemically with the CPZ. When the animal’s weight loss was about 20% of total body weight, CPZ application was halted for a day and continued after the rest day. In all subjects, the maximum time required for rest was only 1 day, and just at the end of the CPZ administration period, some animals lost a maximum of 20% of their body weight.

**Experimental design**

Mice were divided randomly into 6 groups (7 mice in each group). Group 1: normal control (oral administration of distilled water every day for 4 weeks to induce stress same like other groups), group 2: cuprizone control (oral administration of cuprizone 0.2% w/w for 4 weeks), group 3: probiotic control (oral administration of B. coagulans at a concentration of 1 × 10^9 CFU/ml for 4 weeks), group 4: prevention group (oral administration of B. coagulans for 2 weeks then cuprizone for 4 weeks), group 5: Improvement group I (oral administration of cuprizone for 4 weeks then B. coagulans for 2 weeks then cuprizone for 4 weeks), group 6: Improvement group II (oral administration of cuprizone for 4 weeks then B. coagulans and Vitamin D at a concentration of 20 IU/day for 4 weeks).

**RNA isolation and real-time polymerase chain reaction (RT-PCR)**

The expression of genes was quantified by RT-PCR assay and expressed relative to the expression of the β-actin gene. Total RNA was extracted with Trizol reagent (Invitrogen) and used as a template to prepare cDNA using M-MLV RTase system (Takara). Gene expression was quantified using the SYBR Green Real-Time PCR kit (Toyobo) and the StepOnePlus™ Real-Time PCR System (Applied Biosystems). Data were normalized based on β-actin gene expression and presented as normalized gene expression (2 -ΔΔCT; n = 5). The primer sequences used were as follows (Table 1):

**Y-maze behavioral test**

The Y-maze is an uncomplicated two-trial memory test for assessing spatial memory. According to Kim et al. 2007, mice were placed in one arm, and the number and sequence of arm entries were recorded for 10 min. The percentage of triads in which all three arms were show, i.e., CAB, ABC, or BCA but not BAB, was recorded as an alternation to evaluate short-term memory. The maze arms were cleaned completely and sprayed with water between tests to remove remaining smells. The alternation score for each mouse was described as the ratio of the actual number of alternation to the possible number of alternation multiplied by 100 as the following equation:

\[
\left( \frac{\text{number of alternations}}{\text{total arm entries} - 2} \right) \times 100
\]

The total number of arm entries acted as an indicator of short-term spatial memory.

**Table 1** Real-time PCR primers used in gene expression analysis (F: Forward Primer; R: Reverse Primer)

| Gene   | Primer                  |

Immunohistochemistry technique

Immunohistochemical staining was performed using the avidin-biotin method with an antibody against the MBP to evaluate demyelination.

Histological staining

To evaluate the rate of the remyelination, paraffin sections were stained with Luxol fast blue (LFB). After dehydration, brain sections were incubated with 0.1% LFB solution at 60 °C overnight. Following a rinse with 95%, 70% ethanol, and distilled water, the slides were placed in a separate lithium carbonate solution for 30 s and then in 70% ethyl alcohol for another 30 s. The last wash with distilled water was done.

Statistical analysis

For all experiments, data were analyzed using SPSS 23. A comparison between groups was tested by a two-way analysis of variance, followed by a Tukey Test. Statistical significance is considered when \( P < 0.05 \).

Results

_B.coagulans_ treatment reduces pro-inflammatory cytokine expression

The analyses of anti-inflammatory cytokines are shown in Fig. 1. IL-4’s graph shows that there are significant differences between Group 2 as a Cuprizone Control with

![Graphs showing cytokine levels](image)

Fig. 1 IL-4, TGF-beta, IL-17, IFN-gamma cytokine level in the serum of demyelinated mouse model of cuprizone. Asterisks are showing significant differences between _B.coagulans_ administration groups and Normal Control, Cuprizone Control, and Probiotic Control.
Group 4, 5, and 6 (P = 0.000 < 0.05). Also, it shows that there is a significant difference between Group 1 and Group 6 (P = 0.043 < 0.05) and between Group 3 and Group 4 (P = 0.022 < 0.05).

According to TFG-β’s graph, there are significant differences between Group 2 as a Cuprizone Control with Group 4, 5, and 6 (P = 0.000 < 0.05). No significant differences were also found in serum TFG-β of other experimental groups.

**B. coagulans** treatment modulates anti-inflammatory cytokine expression

The analyses of inflammatory cytokines are shown in Fig. 1. The graph of IL-17 demonstrates that there are significant differences between Group 2 as a Cuprizone Control with Group 4, 5, and 6 (P = 0.000 < 0.05). Although, there are some significant differences between Group 3 and Group 5 (P = 0.004 < 0.05) and Group 3 and Group 6 (P = 0.001 < 0.05).

The graph of IFN-γ shows that there are significant differences between Group 2 as a Cuprizone Control with Group 4, 5, and 6 (P = 0.000 < 0.05). It demonstrates that there is a significant difference between Group 1 and Group 4 (P = 0.004 < 0.05). This graph also shows that there is a significant difference between Group 3 and Group 4 (P = 0.010 < 0.05).

**Analysis of genes expression data in different groups**

The effects of probiotic administration on the expression of genes are shown in Fig. 2. The relative expression of the *IDO-1* gene was significantly decreased in the experimental groups compared to the Cuprizone Control Group (P = 0.000 < 0.05). No significant differences were found in *IDO-1* gene expression between Normal and Probiotic Control Groups with experimental Groups.

The relative expression of *CYP27B1* gene was significantly decreased in the experimental groups. Group 4 (P = 0.001 < 0.05), Group 5 (P = 0.000 < 0.05), and Group 6 (P = 0.000 < 0.05) compared to the Cuprizone Control Group.

The relative expression of *NLRP1* gene was significantly decreased in the experimental groups. Group 4 (P = 0.019 < 0.05), Group 5 (P = 0.025 < 0.05), and Group 6 (P = 0.000 < 0.05) compared to the Cuprizone Control Group.

The relative expression of the *NLRP3* gene was significantly decreased in the experimental groups. Group 4 (P = 0.006 < 0.05), Group 5 (P = 0.013 < 0.05), and Group 6 (P = 0.008 < 0.05) compared to the Cuprizone Control Group.

The graph of *AIM2* shows that there is a significant difference between Group 1 and Group 4 (P = 0.049 < 0.05). It also demonstrates that there are some significant differences between Group 4 (P = 0.002 < 0.05), Group 5 (P = 0.000 < 0.05), and Group 6 (P = 0.000 < 0.05) compared to the Cuprizone Control Group.

**Assessing short-term spatial memory using Y-maze**

According to the obtained results shown in Fig. 3, there is a significant difference between the Cuprizone Control Group and experimental groups (P = 0.000 < 0.05).

**Confirmation of demyelination**

The analysis of IHC staining (Fig. 4) demonstrates that there is an acceptable rate of demyelination after 4 weeks of cuprizone administration in 5 and 6 experimental groups in comparison with the normal group (Fig. 5).

**Rate of Remyelination**

The study of LFB staining indicates that there is an acceptable rate of Myelin Decomposition in experimental groups compared with the cuprizone group (Fig. 6).

**Discussion**

Autoimmune diseases can be due to the failure of the tolerance process and the reduction in proliferation of autoreactive T lymphocytes (Konuray and Erginkaya 2018). Both Th1 and Th17 have an important role in the pathogenesis of this disease. On the other hand, Treg cells are considered important cells in establishing tolerance and modulating the immune response (Langdon et al. 2016). Dietary changes in the gut microbiota, overuse of antibiotics, and stress are some of the hypotheses that are considered to increase the risk of MS (Lee et al. 2017). Studies show the MS gut microbiome as having general alterations in specific taxa, some associated with the promotion of inflammatory cytokines and overall inflammation (Lee and Mazmanian 2010). Various important mechanisms underlying the antagonistic effects of probiotics on different microorganisms include the following: modification of the gut microbiota, competitive adherence to the mucosa and epithelium, strengthening of the gut epithelial barrier, and modulation of the immune system to conduct an advantage to the host (Lovelace et al. 2016). Probiotics can influence the immune system by metabolites, cell wall components, and DNA. Immune modulatory effects might be achieved with dead probiotic bacteria or just probiotics-derived components like peptidoglycan fragments or DNA (Jones et al. 2012). In
In this study, one of the measured cytokines is IFN-γ, which is involved in the pathogenesis of Multiple sclerosis and its level is increased in this disease. In this study, we showed that *B. coagulans* decreased the IFN-γ level, which was consistent with previous studies. Researches have shown that injection of IFN-γ to patients with MS causes attacks, and also the IFN-γ serum level rising before attacks, indicating that disease activity and recurrence are initially related to Th1 activity (Mancuso et al. 2015; McMurrant 2018). On the other hand, IFN-β was found to reduce the secretion of IFN-γ from peripheral blood mononuclear cells and improve the patient’s clinical condition (Mittal et al. 2014). Jensen et al. also studied the effect of *B. coagulans* on the inflammatory properties of IFN-γ. Their results showed that these bacteria increased cytokine levels, which contradicts our results (Oelschlaeger 2010). During a study on a mouse model, Dargahi et al. showed that *Streptococcus thermophilus* reduces the secretion of inflammatory cytokines such as IFN-γ and IL-1β and continuous use of this probiotic can be effective in controlling and treating autoimmune diseases such as MS (Olcum et al. 2020). Lee et al. have also shown in the mouse model of colitis after treatment with lactic acid probiotics, the level of IFN-γ and IL-1β dropped (Ortiz et al. 2016). In a study of the mouse model of EAE by He et al., it was found that the use of oral *Lactobacillus reuteri* could lead to a decrease in Th1/Th17 cells and related cytokines IFN-γ/IL-17. They also showed that the loss of intestinal microbiota diversity that occurred with model induction was regenerated by this probiotic (Ostadmohammadi et al. 2019). Cosorich et al. found that increased frequency of TH17 cells correlates with high disease activity and with specific alterations of the gut mucosa-associated microbiota in MS patients (Owaga et al. 2015). Many studies have suggested that probiotics have the ability to inhibit pro-inflammatory IL-17 production and activation in Th17-related diseases (Riazi et al. 2009; Rosenblum et al. 2015). Secher et al. indicated that beneficial traits were associated with a decreased secretion of inflammatory cytokines such as IL-17, IFN-γ, and TNF-α and an increase in the production of IL-10 as an anti-inflammatory cytokine by autoreactive CD4+ T-cells, CD4+ Foxp3+ in lymph nodes (Salehipour et al. 2017). Kobayashi et al. in their work indicated that administration of *Lactobacillus casei* strain Shirota on the mouse model of EAE upregulated IL-17 and IFN-γ in inguinal lymph nodes cells (Schattling et al. 2014). In this research we found that *B. coagulans* decreased the IL-17 level, which is similar to other studies. Singh et al. in their work demonstrated that VSL#3 administrations did not lead to any changes in gut flora, but led to a reduction in the frequency of Th17 cells and in the production of pro-inflammatory cytokine on lipopolysaccharide stimulation (Secher et al. 2017). Other studies showed that beneficial probiotic bacteria suppress pathogenic Th17 cells and induce steady-state Th17 cells (Singh et al. 2018). Salehipour et al. investigated the effect of 10^9 CFU/mL *Lactobacillus plantarum A7, Bifidobacterium animalis* and a combination of these probiotics in an experimental model of MS. They reported that *L. plantarum A7* and *B. animals* could ameliorate EAE condition through enhancing the anti-inflammatory cytokines and cell, such as IL-10, IL-4, and TGF-β, Tregs, CD4+, CD25+, and Foxp3+ in spleen and lymph nodes together with increasing Th2 and Treg in spleen and brain (Sintzel et al. 2018). In present research, we also found *B. coagulans* has modulatory effect on IL-4 and TGF-β and this could confirm the modulating properties of probiotics. Recently, a promising evidence of synergic effects of combined supplementation with vitamin D and probiotics in modulating the gut microbiota and metabolome is emerging (Smolders et al. 2013). Also, numerous observational studies have suggested that there is a correlation between the level of serum vitamin D and MS risk and disease activity (Tanabe 2013). Smolders et al. indicated that there are high levels of CYP27B1 protein in MS lesions and normal appearing white matter, but not in white matter from healthy control subjects (Tesmer et al. 2008). We also found that *B. coagulans* decreased the CYP27B1 gene expression level, which is similar to prior studies. Another of the genes investigated in this study was the IDO-1 gene. Our results showed that cuprizone significantly enhanced the expression in comparison with the control group, and also between treatment groups, consumption of this bacteria significantly reduced the expression in comparison with the cuprizone group. Measurement of IDO gene expression and activity in blood could be a useful marker to monitor the clinical course of RR-MS. Therapeutic interventions modulating IDO activity may be beneficial in MS (Usami et al. 2015). Wetzel et al. investigated that Expression of IDO1 but not IDO2 was upregulated in the spinal cord during peak symptoms of EAE (Vujkovic-Cvijin et al. 2015). Cvijin et al. also showed IDO1 activity correlates with loss of barrier-promoting Th17 cells in HIV/simian immunodeficiency virus infection. They proposed that *Lactobacillus* species inhibit mammalian IDO1 and thus may help to preserve Th17 cells during pathogenic SIV infection, providing support for Lactobacillus species as modulators of mucosal immune homeostasis (Wetzel et al. 2020). Dighehsara et al. demonstrated that the administration of *L. casei* decreased the expression of IDO1 in mouse model of cuprizone (Wu and Wu 2012) which is consistent with our results.
Another studied pathway in this article is the Inflammasome pathway which has been tested by the expression of NLRP1, NLRP3, and AIM2. According to our results, there is a significant reduction in expression between treatment groups and the cuprizone group in all three genes. In a study Michailidou et al. showed inhibition of the complement system by PMX205 decreased genes that are keys for inflammasome-related microglial activation: NLRP3, IL-1b, ASC, AIM2, NLR Family Pyrin Domain Containing 1-NLRP1, NLRC4. PMX205 was also able to reduce IL-1b and Iba1 protein expressions that correlated with reduced demyelination, the extent of axonal injury and improve clinical scores (Yan and Polk 2011). Remyelination as a critical factor in Multiple sclerosis has been targeted in our study. Because of the immune modulatory effects of *B. coagulans*, we have seen that the rate of remyelination in treatment groups increased significantly in compare to cuprizone control group. McMurran also investigated the potential of a therapeutic probiotic (VSL#3) to improve remyelination in aged mice. He figured out that In contrast to antibiotic treatment, probiotic administration caused a slight enhancement in the onset of inflammation following focal demyelination (Yu et al. 2016) and our result is similar. We analyzed spatial memory by Y-Maze so according to the results there was a significant increasing in alternation percentage in treatment groups and cuprizone group. Benton et al. proof that

![Y-Maze graph](image)

**Fig. 3** *B. coagulans* administration enhances spatial cognition in a demyelinated mouse model of cuprizone. The mean alternative rate in the Y-Maze. Asterisks are showing significant differences between *B. coagulans* administration groups and Normal Control, Cuprizone Control, and Probiotic Control.

![IHC staining images](image)

**Fig. 4** 1. IHC staining indicated the rate of myelin in the Normal group (magnification:400X) 1.A.Nuclei stained by Propidium iodide 1.B.Primary antibody 1.C.Merge 2. the consumption of probiotic-containing yoghurt improved
the mood of those whose mood was initially poor (Zhen
et al. 2017). The results of Ho et al. highlighted a possible
antioxidative effect triggered by short-chain fatty acids
that contributed to improving the memory and learning
abilities following treatment with the probiotic mixture
and suggested that probiotics could serve as a therapy to
modulate physiological function (Ziemssen and Ziemssen
2005).

In conclusion the data presented in the present study show
that oral administration of \textit{B. coagulans} to the demyelinated
mouse model of cuprizone modulates immune responses.
This probiotic increases the percentage of alternation behav-
or and the rate of remyelination. On the other hand, this
strain decreases IFN-γ, IL-17, and modulates IL-4, and
TGF-β in serum level. Therefore, according to the data of
this study, it seems that \textit{B. coagulans} could suppress Th17
and Th1 responses and help to provide a proper adaptive
immune response as well as innate immune response by
decreasing the expression of Inflammasome pathway related
genes. \textit{B. coagulans} inhibits the expression of IDO1, so it has
effects on the Kynurenine pathway by decreases the deple-
tion of Trp and production of neurodegenerative metabolites.
As the less Trp enters to Kynurenine pathway, more will be
available to get to the serotonin pathway. The synergic effect
of combined probiotic and vitamin D creates a proper mix
to shows a significant difference between prevention and
treatment groups compares to cuprizone control group in
CYP27b1 gene expression.
