INARIANT CR STRUCTURES ON COMPACT HOMOGENEOUS MANIFOLDS

Dmitry V. Alekseevsky and Andrea F. Spiro

Abstract. An explicit classification of simply connected compact homogeneous CR manifolds $G/L$ of codimension one, with non-degenerate Levi form, is given. There are three classes of such manifolds:

a) the standard CR homogeneous manifolds which are homogeneous $S^1$-bundles over a flag manifold $F$, with CR structure induced by an invariant complex structure on $F$;

b) the Morimoto-Nagano spaces, i.e. sphere bundles $S(N) \subset TN$ of a compact rank one symmetric space $N = G/H$, with the CR structure induced by the natural complex structure of $TN = G/HC$;

c) the following manifolds: $SU_n/T^1 \cdot SU_{n-2}, SU_p \times SU_q/T^1 \cdot U_{p-2} \cdot U_{q-2}, SU_n/T^1, SU_2 \cdot SU_2 \cdot SU_{n-4}, SO_{10}/T^1 \cdot SO_6, E_6/T^1 \cdot SO_8$; these manifolds admit canonical holomorphic fibrations over a flag manifold $(F, J_F)$ with typical fiber $S(S^k)$, where $k = 2, 3, 5, 7$ or 9, respectively; the CR structure is determined by the invariant complex structure $J_F$ on $F$ and by an invariant CR structure on the typical fiber, depending on one complex parameter.

1. Introduction.

An almost CR structure on a manifold $M$ is a pair $(\mathcal{D}, J)$, where $\mathcal{D} \subset TM$ is a distribution and $J$ is a complex structure on $\mathcal{D}$. The complexification $\mathcal{D}^\mathbb{C}$ can be decomposed as $\mathcal{D}^\mathbb{C} = \mathcal{D}^{10} + \mathcal{D}^{01}$ into sum of complex eigendistributions of $J$, with eigenvalues $i$ and $-i$.

An almost CR structure is called integrable or, shortly, CR structure if the distribution $\mathcal{D}^{01}$ (and hence also $\mathcal{D}^{10}$) is involutive, i.e. with space of sections closed under Lie bracket. This is equivalent to the following conditions:

$$J([JX,Y] + [X,JY]) \in \mathcal{D},$$

$$[JX,JY] - [X,Y] - J([JX,Y] + [X,JY]) = 0,$$

for any two fields $X, Y$ in $\mathcal{D}$.

A map $\varphi: (M, \mathcal{D}, J) \to (M', \mathcal{D}', J')$ between two CR manifolds is called holomorphic map if $\varphi_*(\mathcal{D}) \subset \mathcal{D}'$ and $\varphi_*(JX) = J'\varphi_*(X)$.

1991 Mathematics Subject Classification. Primary 32C16; Secondary 53C30 53C15.

Key words and phrases. Homogeneous CR manifolds, Real Hypersurfaces, Contact Homogeneous manifolds.
Two CR structures \((D, J)\) and \((D', J')\) are called equivalent if there exists a diffeomorphism such that \(\phi_*(D) = D'\) and \(\phi_*(J) = J'\).

The codimension of \(D\) is called codimension of the CR structure. Note that a CR structure of codimension zero is the same as a complex structure.

A codimension one CR structure \((D, J)\) on a \(2n + 1\)-dimensional manifold \(M\) is called Levi non-degenerate if \(D\) is a contact distribution. This means that any local (contact) 1-form \(\theta\), which defines the distribution (i.e., such that \(\ker \theta = D\)) is maximally non-degenerate, that is \((d\theta)^n \wedge \theta \neq 0\).

Note that any real hypersurface \(M\) of a complex manifold \(N\) has a natural codimension one CR structure \((D, J_D)\) induced by the complex structure \(J\) of \(N\), where

\[
D = \{ X \in TM , JX \in TM \} , \quad J_D = J|_D .
\]

In the following, if the opposite is not stated, by CR structure we will mean integrable codimension one Levi non-degenerate CR structure. Sometimes, if the contact distribution \(D\) is given, we will identify a CR structure with the associated complex structure \(J\).

A CR manifold, that is a manifold \(M\) with a CR structure \((D, J)\), is called homogeneous if it admits a transitive Lie group of holomorphic transformations. If the opposite is not stated, we will always assume that the homogeneous CR manifold \((M, D, J)\) is simply connected.

The aim of this paper is to give a complete classification of simply connected homogeneous CR manifolds \(M = G/L\) of a compact Lie group \(G\). This gives a classification of all simply connected homogeneous CR manifolds, since any compact homogeneous CR manifold admits a compact transitive Lie group of holomorphic transformations (see [12]).

The simplest example of compact homogeneous CR manifold is the standard sphere \(S^{2n-1} \subset \mathbb{C}^n\) with the induced CR structure.

More elaborated examples are provided by the following construction of A. Morimoto and T. Nagano ([9]). Let \(N = G/H\) be a compact rank one symmetric space (shortly ‘CROSS’). The tangent space \(TN\) can be identified with the homogeneous space \(G^C/H^C\). Hence, it admits a natural \(G^C\)-invariant complex structure \(J\). Any regular orbit \(G \cdot p = S(N) \simeq G/L\) in \(TN = G^C/H^C\) is a sphere bundle; in particular it is a real hypersurface with (Levi non-degenerate) \(G\)-invariant CR structure.

Moreover, these examples together with the standard sphere \(S^{2n-1} \subset \mathbb{C}^n\) exhaust the class of CR structures induced on a codimension one orbit \(M = G \cdot x \subset C\) of a compact Lie group \(G\) of holomorphic transformations of a Stein manifold \(C\). We call the homogeneous CR manifolds which are equivalent to such orbits \(G \cdot p = S(N)\) in the tangent space of a CROSS Morimoto-Nagano spaces.

In the fundamental paper [1], H. Azad, A. Huckleberry and W. Richthofer showed that these manifolds play a basic role in the description of compact homogeneous CR manifolds (see also [8] and [11]).

More precisely, for any compact homogeneous CR manifold \(M = G/L\) they define a holomorphic map (called anticanonical map) \(\phi : M = G/L \to \mathbb{CP}^N\). This map is \(G\)-equivariant with respect to some explicitly defined projective action of \(G\) on \(\mathbb{CP}^N\). For any compact homogeneous CR manifold \(M\) only two possibilities may occur: the orbit \(\phi(M) = G \cdot p, p \in \phi(M)\), is either a flag manifold with the
complex structure induced by the complex structure $J_P$ of $\mathbb{C}P^N$ and in this case $\phi: M \to \phi(M)$ is an $S^1$-fibered, or it is a CR manifold with CR structure induced by $J_P$ and in this case $\phi: M \to \phi(M)$ is a finite covering.

This reduces the description of CR homogeneous manifolds of the second type to the description of compact orbits $G \cdot p \subset \mathbb{C}P^N$ of a real subgroup $G \subset \text{Aut}(\mathbb{C}P^N)$ of projective transformations, on which $J_P$ induces a CR structure.

A simple argument shows that an orbit $G \cdot p \subset \mathbb{C}P^N$ of a connected Lie subgroup $G \subset \text{Aut}(\mathbb{C}P^N)$ carries a (possibly Levi degenerate) CR structure induced by $\mathbb{C}P^N$ if and only if $G \cdot p$ is a real hypersurface of $G^C \cdot p$. Moreover, if the orbit is compact, one may assume that $G$ is a compact semisimple Lie group.

The following important result in [1] describes the structure of such orbits.

**Theorem.** Let $G^C \subset \text{Aut}(\mathbb{C}P^N)$ be a connected complex semisimple group of projective transformations and $G$ its compact form. Assume that the orbit $M = G \cdot p = G/L$ carries a Levi non-degenerate CR structure induced by $J_P$ and hence it is a real hypersurface in $B = G^C \cdot p = G^C / H$. Denote by $P$ a minimal parabolic subgroup of $G^C$ which properly contains $H$. Then the fiber $C = P/H$ of the $G^C$-equivariant fibration

$$\pi: B = G^C / H \to F = G^C / P$$

over the flag manifold $F = G^C / P$ is a homogeneous Stein manifold biholomorphic to $\mathbb{C}^n$ or to the tangent space of a CROSS.

This fibration is called *Stein-rational fibration*. Note that $P$ not necessarily acts effectively on $C$.

The Stein-rational fibration induces a $G$-equivariant holomorphic fibration of the homogeneous CR manifold $M = G/L$ over the flag manifold $F$

$$\pi': M = G/L \to F = G^C / P$$

(it is a *CRF fibration* according to our definitions, see below). Moreover, in correspondence to a fiber of $\pi$, a fiber of $\pi'$ is either $S^1$, $S^{2n-1}$ or a Morimoto-Nagano space.

This Theorem gives necessary conditions for the induced CR structure on $M = G \cdot p \subset \mathbb{C}P^N$ being Levi non-degenerate. Our classification gives necessary and sufficient conditions. In particular, we show that only the sphere bundles $S(S^k)$ with $k = 2, 3, 5, 7, 9$ and $11$ occur as fibers of the fibration $\pi'$.

Now we describe the main results of this paper. Section §2 collects the basics facts on homogeneous CR manifolds.

Section §3 is devoted to the infinitesimal description of homogeneous contact manifolds $M = G/L$ of a compact Lie group.

We prove that the center of $G$ is at most one dimensional and we establish a natural one to one correspondence between simply connected homogeneous manifolds $M = G/L$ with an invariant contact distribution $\mathcal{D}$ and an element $Z \in \mathfrak{g} = \text{Lie}(G)$ (defined up to scaling) such that:

- a) the centralizer of $Z$ has the following orthogonal decomposition

$$C_\mathfrak{g}(Z) = \mathfrak{l} \oplus \mathbb{R}Z , \quad \mathfrak{l} = \text{Lie}(L)$$

w.r.t. the Cartan-Killing form $\mathcal{B}$;

- b) the 1-parametric subgroup generated by $Z$ is closed.
This element $Z$ (called contact element) defines an orthogonal decomposition
\[ g = l + \mathbb{R}Z + m. \]

The subspace $m$ is $\text{Ad}_L$-invariant and defines the contact distribution $\mathcal{D}$ on $M = G/L$, while the $\text{Ad}_L$-invariant 1-form $\theta = B \circ Z \in g^*$ is extended to a $G$-invariant contact form $\theta$ on $G/L$.

We associate to $Z$ a flag manifold $F_Z$, which is the adjoint orbit
\[ F_Z = \text{Ad}_{G}(Z) = G/K, \]
where $K = C_G(Z)$ is the centralizer of $Z$. There is a natural principal $S^1$-fibration
\[ \pi: M = G/L \longrightarrow F_Z = G/K. \]

In general, a homogeneous manifold $G/L$ admits no more than one invariant contact structure. If it admits more than one then it is called special contact manifold.

The main examples of such manifolds can be described as follows.

Let $G$ be a simple compact Lie group without center and let $Q = G/Sp_1 \cdot H'$ be the associated Wolf space, that is the homogeneous quaternionic Kähler manifold, where $Sp_1 \cdot H'$ is the normalizer in $G$ of the 3-dimensional subalgebra $\mathfrak{sp}_1(\mu)$ of $\mathfrak{g}$ associated with the maximal root $\mu$. Then the associated 3-Sasakian homogeneous manifold $M = G/H'$ is a special contact manifold.

Any $0 \neq Z \in \mathfrak{sp}_1(\mu)$ is a contact element. Furthermore, any two invariant contact structures on $M$ are equivalent under a transformation, which commutes with $G$, defined by the right action of an element from $Sp_1$.

We prove the following theorem.

**Theorem 1.1.** Any special contact manifold $M = G/L$ is either the 3-Sasakian homogeneous manifold $G/H'$ of a simple Lie group $G$, described above, or $M = G_2/Sp_1$, where $Sp_1$ is the 3-dimensional subgroup of the exceptional Lie group $G_2$, with Lie algebra $\mathfrak{sp}_1(\mu)$, where $\mu$ is the maximal root of $G_2$.

In section §4 we establish some general properties of compact homogeneous CR manifolds. Let $(M = G/L, \mathcal{D})$ be a homogeneous contact manifold and
\[ g = l + \mathbb{R}Z + m \]
the associated decomposition of $g$. Then any invariant (integrable) CR structure $J$ is defined by the $\text{Ad}_L$-invariant decomposition
\[ m^C = m^{10} + m^{01} \tag{1.1} \]
of the complexified tangent space $m^C = T_{eL}^CM$ into holomorphic and antiholomorphic subspaces; this decomposition is such that
\[ l^C + m^{10} \text{ is a subalgebra of } g^C. \tag{1.2} \]

The subspace $m$ is naturally identified with the tangent space of the associated flag manifold $F_Z = G/K$, $\mathfrak{k} = l + \mathbb{R}Z = \text{Lie}(K)$. It is known that any invariant complex structure on $F_Z$ is defined by an $\text{Ad}_K$-invariant decomposition (1.1), where $m^{10}$ is
a subalgebra (in fact it is the nilradical of a parabolic subalgebra $\mathfrak{t}^C + \mathfrak{m}^{10}$). Hence any invariant complex structure $J_F$ on $F_Z$ defines an invariant CR structure $J_M$ on $M = G/L$. It is called standard CR structure induced by $J_F$.

The natural $S^1$-fibration $\pi: M = G/L \rightarrow F_Z = G/K$ is holomorphic with respect to the CR structure $J_M$ and the complex structure $J_F$.

Since the description of all invariant complex structures on a flag manifold is known (see e.g. [10], [4], [5], [3]), it is sufficient to classify the non-standard CR structures.

The following notion is important for such classification. A compact homogeneous CR manifold $(M = G/L, D, J)$ is called non-primitive if it admits a holomorphic $G$-equivariant fibration $\pi$ (called CRF-fibration)

$$\pi: M = G/L \rightarrow F = G/Q,$$

where $F = G/Q$ is a flag manifold of positive dimension, equipped with an invariant complex structure $J_F$.

Note that a fiber of $\pi$ is a homogeneous compact CR manifold $Q/L$ and that any standard CR manifold is non-primitive.

The classification of primitive CR structures given in §5 and §6 is an important step for classification of non-standard CR structures.

A basic tool for studying the homogeneous CR manifolds is the anticanonical map $\phi$ defined in [1]. Let $(M = G/L, D_Z, J)$ be a homogeneous CR manifold of a compact Lie group $G$ and

$$\mathfrak{g}^C = \mathfrak{t}^C + \mathfrak{c}Z + \mathfrak{m}^{10} + \mathfrak{m}^{01}$$

the corresponding decomposition of $\mathfrak{g}^C$. Then the anticanonical map $\phi$ is the holomorphic map of $M$ into the Grassmanian of $k$-planes, $k = \dim_C(\mathfrak{t}^C + \mathfrak{m}^{01})$, given by

$$\phi: M = G/L \rightarrow Gr_k(\mathfrak{g}^C) \subset \mathbb{C}P^N$$

$$\phi: gL \mapsto \text{Ad}_g([\mathfrak{t}^C + \mathfrak{m}^{01}]).$$

Note that $\phi$ is a $G$-equivariant map onto the orbit $G \cdot p$ of $p = [\mathfrak{t}^C + \mathfrak{m}^{01}] \in Gr_k(\mathfrak{g}^C)$ under the natural adjoint action of $G$ on $Gr_k(\mathfrak{g}^C)$.

We obtain the following characterization of standard CR structures (see Theorems 4.9 and 4.11):

**Theorem 1.2.** Let $(M = G/L, D_Z, J)$ be a homogeneous CR manifold.

1. If it is standard, then the image $\phi(M) = G \cdot p$ of the anticanonical map is the flag manifold $F_Z = G/K$, associated with the contact structure $D_Z$. Hence $\phi: M \rightarrow \phi(M) = F_Z$ is the natural $S^1$-fibration.

2. If it is non-standard, then $\phi: M \rightarrow \phi(M) = G \cdot p$ is a finite holomorphic covering, with respect to the CR structure of $G \cdot p \subset Gr_k(\mathfrak{g}^C)$ induced by the complex structure of $Gr_k(\mathfrak{g}^C)$.

In section §5, we classify all invariant CR structures on special contact manifolds $G/L$. The result is the following:
Theorem 1.3. Let $M = G/L$ be a special contact manifold with an invariant contact structure $\mathcal{D}_Z$.

1. If $G \neq SU_n$, then there exists (up to sign of $J$) only one invariant CR structure $(\mathcal{D}_Z, J)$, which is standard;
2. If $G = SU_2$ and hence $M = SU_2$, then any CR structure is non-primitive and it admits a CRF fibration with typical fiber $S^1$;
3. If $G = SU_n$, $n > 2$, and hence $M = SU_n/U_{n-2}$, then there exist (up to sign of $J$) three standard CR structures and three 1-parameter families of non-standard CR structures; one of such families consists of primitive CR structures; any other non-standard CR structure is non-primitive and it admits a CRF fibration

$$
\pi_1: M = SU_n/U_{n-2} \to Q_1 = SU_n/T^1 \cdot U_{n-2}
$$

with fiber $S^1$ over the flag manifold $Q_1 = SU_n/T^1 \cdot U_{n-2}$; moreover, any non-standard, non-primitive CR structure admits also a CRF fibration

$$
\pi: M = SU_n/U_{n-2} \to Q_2 = SU_n/S(U_2 \cdot U_{n-2})
$$

with fiber $SO_4$ and base given by the Wolf space $Q_2 = SU_n/S(U_2 \cdot U_{n-2})$, equipped with its (unique up to sign) complex structure.

The explicit description of all non-standard CR structures on $SU_2$ and $SU_n/U_{n-2}$ is given in Proposition 5.1.

In section §6, we obtain the classification of non-standard invariant CR structures on non-special homogeneous contact manifolds.

Together with above results it leads to the following classification of primitive CR structures.

Theorem 1.4. Let $(M = G/L, \mathcal{D}_Z, J)$ be a simply connected, primitive, homogeneous CR manifold and let $\vartheta = B \circ Z |_1$ be the dual form of the contact element $Z$ restricted to a Cartan subalgebra of $\mathfrak{g} = C_G(Z) = 1 + \mathbb{R}Z$. Then $G/L$ is isomorphic to the universal covering space of a sphere bundle $S(N) \subset T(N)$ of a CROSS $N$. The groups $G$, $K = C_G(Z)$, the form $\vartheta = -i\vartheta$ and the CROSS $N$ are listed in the following table.

| $n^0$ | $G$ | $K = C_G(Z)$ | $\vartheta$ | $N = G/H$ |
|-------|-----|--------------|------------|----------|
| 1     | $SU_2 \times SU'_2$ | $T^1 \times T^1'$ | $(\varepsilon_1 - \varepsilon_2) + (\varepsilon'_1 - \varepsilon'_2)$ | $S^3 = \frac{SO_4}{SO_3}$ |
| 2     | $Spin_7$ | $T^1 \cdot SU_3$ | $\varepsilon_1 + \varepsilon_2 + \varepsilon_3$ | $S^7 = \frac{Spin_7}{G_2}$ |
| 3     | $F_4$ | $T^1 \cdot SO_7$ | $\varepsilon_1$ | $\mathbb{C}P^2 = \frac{F_4}{Spin_9}$ |
| 4     | $SO_{2n+1}$, $n > 1$ | $T^1 \cdot SO_{2n-1}$ | $\varepsilon_1$ | $S^{2n} = \frac{SO_{2n+1}}{SO_{2n}}$ |
| 5     | $SO_{2n}$, $n > 2$ | $T^1 \cdot SO_{2n-2}$ | $\varepsilon_1$ | $S^{2n-1} = \frac{SO_{2n}}{SO_{2n-1}}$ |
| 6     | $SU_{n+1}$, $n > 1$ | $T^1 \cdot U_{n-1}$ | $\varepsilon_1 - \varepsilon_2$ | $\mathbb{C}P^n = \frac{SU_{n+1}}{U_n}$ |
| 7     | $Sp_n$ | $T^1 \cdot Sp_1 \cdot Sp_{n-2}$ | $\varepsilon_1 + \varepsilon_2$ | $\mathbb{H}P^{n-1} = \frac{Sp_n}{Sp_1 \cdot Sp_{n-1}}$ |
In each of these cases, the set of all invariant CR structures (considered up to sign) on $M = G/L$ is parameterized by the points of the unit disc $D$ in $\mathbb{R}^2$. The center of $D$ corresponds to the (unique) standard CR structure of $M$ and all other points correspond to primitive CR structures.

The explicit description of all non-standard CR structures on these manifolds is given in Corollary 5.2 and Propositions 6.3 and 6.4.

For what concerns the non-primitive and non-standard CR structures, we have the following theorem (for an explicit description of the CR structures, see also Theorem 5.1 and Proposition 6.5).

**Theorem 1.5.** Let $(M = G/L, D, J)$ be a simply connected homogeneous CR manifold with a non-standard CR structure.

Then, either $M = SU_2$ or there exists a unique CRF fibration

$$\pi: M = G/L \rightarrow F = G/Q$$

over a flag manifold $F$ with an invariant complex structure $J_F$, such that the fiber $C = Q/L$ is either a primitive CR manifold or is equal to $SO_3 = S(S^2)$. Moreover the groups $G$, $L$, the primitive fiber $C = Q/L$ and the flag manifold $F = G/Q$ are as in the following table (in n.2, the subgroups $U_{p-2}$ and $U_{q-2}$ of $L$ are subgroups of the factors $SU_p$ and $SU'_q$ of $G$, respectively):

| $n^a$ | $G$ | $L$ | $C = Q/L$ | $F = G/Q$ |
|-------|-----|-----|-----------|-----------|
| 1     | $SU_n$ | $T^1 \cdot SU_{n-2}$ | $SO_3 = S(S^2)$ | $SU_p \frac{SU_p}{SU_p \times SU'_q}$ |
| 2     | $SU_p \times SU'_q$ | $T^1 \cdot U_{p-2} \cdot U'_{q-2}$ | $SO_4 \frac{SO_4}{SO_4 \times SU'_2}$ | $SU_p \frac{SU_p}{SU_p \times SU'_q}$ |
| 3     | $SU_n$ | $T^1 \cdot (SU_2 \times SU_2) \cdot SU_{n-4}$ | $SO_8 \frac{SO_8}{SO_8}$ | $SU_p \frac{SU_p}{SU_p \times SU'_q}$ |
| 4     | $SO_{10}$ | $T^1 \cdot SO_6$ | $SO_8 \frac{SO_8}{SO_8}$ | $SO_{10} \frac{SO_{10}}{SO_{10} \times SU'}$ |
| 5     | $E_6$ | $T^1 \cdot SO_8$ | $SO_8 \frac{SO_8}{SO_8}$ | $E_6 \frac{E_6}{SO_{10} \times SU'}$ |

In particular, the fiber $C$ is a sphere bundle $S(S^r) \subset TS^r$ where $r = 2, 3, 5, 7$ or 9. The CR manifolds in n.1 admit also a CRF fibration with fiber $S^1$.

**Corollary 1.6.** Let $\pi: M = G/L \rightarrow F = G/Q$ be the CRF fibration of a non-primitive non-standard CR manifold $(G/L, D, J_0)$ onto the flag manifold $F = G/Q$ with a fixed invariant complex structure $J_F$. Then the set of all invariant CR structures $(D, J)$ on $G/L$ (up to sign of $J$), such that the fibering $\pi: M = G/L \rightarrow F = G/Q$ is holomorphic, is parameterized by the points of the unit disc $D$ in $\mathbb{R}^2$. The center of $D$ corresponds to the unique standard CR structure $J_s$ of this family and all other points correspond to non-standard CR structures.

The unique standard CR structure $J_s$ on $M = G/L$ such that the fibration $\pi: M = G/L \rightarrow F = G/Q$ is holomorphic w.r.t. $J_s$ and $J_F$ is called the standard CR structure associated with the non-standard CR structure $J_0$. 
Finally we give the description of all non-primitive CR manifolds $G/L$ of a given compact Lie group $G$ in terms of painted Dynkin graphs of $\mathfrak{g} = \text{Lie}(G)$, that is of Dynkin graphs of the Lie algebra $\mathfrak{g}$ with nodes painted in three colors: white ($\circ$), black ($\bullet$) and 'grey' ($\otimes$).

Recall that any flag manifold $F = G/Q$ with an invariant complex structure $J_F$ is defined (up to equivalence) by a black-white Dynkin graph, where the subalgebra $\mathfrak{q} = \text{Lie}(Q)$ is generated by the Cartan subalgebra and the root vectors associated with the white nodes. The complex structure $J_F$ is determined by the decomposition

$$\mathfrak{g}^C = \mathfrak{q}^C + \mathfrak{m}^{10} + \mathfrak{m}^{01}$$

where $\mathfrak{m}^{10}$ is the nilpotent subalgebra generated by the root vectors associated to black nodes (see e.g. [3], [4]).

With a painted Dynkin graph $\Gamma$ (equipped by simple roots in a standard way), we associate two flag manifolds $F_1(\Gamma) = G/K$ and $F_2(\Gamma) = G/Q$ and two invariant complex structure $J_1(\Gamma)$ and $J_2(\Gamma)$ on $F_1(\Gamma)$ and $F_2(\Gamma)$, respectively, as follows. The pairs $(F_1(\Gamma) = G/K, J_1(\Gamma))$ and $(F_2(\Gamma) = G/Q, J_2(\Gamma))$ are the flag manifolds with invariant complex structures defined by the black-white graphs obtained from $\Gamma$ by considering the grey nodes as black and, respectively, white.

Note that $Q$ contains $K$ and that the natural fibration

$$\varpi: F_1(\Gamma) = G/K \to F_2(\Gamma) = G/Q$$

is holomorphic and a fiber $Q/K$ is a flag manifold with an induced invariant complex structure $J'$. Moreover, $J_1(\Gamma)$ is canonically defined by $J_2(\Gamma)$ and $J'$.

Conversely, if $F_1 = G/K$ and $F_2 = G/Q$ are two flag manifolds with invariant complex structures $J_1$ and $J_2$ such that $Q \supset K$ and the equivariant fibration $\varpi: F_1 \to F_2$ is holomorphic, then we may associate with $F_1$ and $F_2$ a painted Dynkin graph in an obvious way.

**Definition 1.7.** A CR-graph is a pair $(\Gamma, \vartheta(\Gamma))$, formed by a painted Dynkin graph $\Gamma$ and a linear combination $\vartheta(\Gamma)$ of simple roots, given in the following table:

| Type | $\mathfrak{g}$ | $\Gamma$ | $\vartheta(\Gamma)$ |
|------|---------------|----------|---------------------|
| $I$  | $A_n$ $(n>1)$ | $\otimes \bullet \cdots \circ$ | $\varepsilon_1 - \varepsilon_2$ |
| $II$ | $A_p + A'_q$ $(p+q>2)$ | $\otimes \bullet \cdots \circ$ | $(\varepsilon_1 - \varepsilon_2) - (\varepsilon'_1 - \varepsilon'_2)$ |
| $III$ | $A_n$ $(n>3)$ | $\circ \bullet \cdots \otimes$ | $\varepsilon_1 + \varepsilon_2 - \varepsilon_3 - \varepsilon_4$ |
| $IV$ | $D_5$ | $\bullet - \cdots \otimes$ | $\varepsilon_{n-3} + \varepsilon_{n-2} + \varepsilon_{n-1} + \varepsilon_n$ |
| $V$  | $E_6$ | $\otimes \circ \circ$ | $2\varepsilon_1 + \varepsilon_6 + \varepsilon$ |

The correspondence between nodes and simple roots is as in Table 4 of the Appendix.
The CR-graphs of type I are called special CR-graph. All the others are called non-special CR-graphs.

Let \((\Gamma, \vartheta(\Gamma))\) be a CR-graph. We fix a Cartan subalgebra \(h\) of the associated compact Lie algebra \(g\) and define the element \(Z(\Gamma) = iB^{-1} \circ \vartheta(\Gamma) \in h\). Then \(Z(\Gamma)\) is a contact element and we call the corresponding contact manifold \((M(\Gamma) = G/L, D_{Z(\Gamma)})\) the contact manifold associated with the CR-graph \((\Gamma, \vartheta(\Gamma))\). Note that \(M(\Gamma)\) is special if and only if the CR-graph is special.

Using the concept of CR-graph, the results of our classification may be stated as follows.

**Theorem 1.8.** Let \(M = G/L\) be a simply connected, homogeneous CR manifold with a non-primitive, non-standard CR structure \((D_z, J)\). Suppose also that \(M \neq SU_2\).

Denote by \(\pi: G/L \to F_Z = G/K\) the natural (non-holomorphic) fibration associated with the contact structure \(D_z\) and by \(\pi': G/L \to F_2 = G/Q\) the unique CRF fibration over a flag manifold \(F_2 = G/Q\) with invariant complex structure \(J_2\), with non-standard fiber \(Q/L\) of minimal dimension, which is either primitive or admitting a CRF fibration with fiber \(S^1\).

Then \(Q \supset K\) and the sequence of fibering

\[
M = G/L \longrightarrow F_Z = G/K \longrightarrow F_2 = G/Q
\]

is holomorphic with respect to the standard CR structure \((D, J_s)\) on \(M\), associated to \((D, J)\), the corresponding complex structure \(J_s\) on \(F_Z\) and the complex structure \(J_2\) on \(F_2\).

Moreover, the painted Dynkin graph \(\Gamma\) associated to the flag manifolds \(F_1 = F_Z\), \(F_2\) with complex structures \(J_1 = J_s\) and \(J_2\), respectively, is a CR graph and (up to a transformation from the Weyl group) \(Z\) is proportional to \(Z(\Gamma)\).

Conversely, if \(\Gamma\) is a CR-graph, then there exists a unique homogeneous contact manifold \((M = G/L, D_z)\) such that \(Z = Z(\Gamma)\) and \(F_Z = F_1(\Gamma) = G/K\). The complex structure \(J_1(\Gamma)\) defines the unique standard CR structure \((D_z, J_1(\Gamma))\) on \(M\) such that the sequence of fibrations

\[
M = G/L \longrightarrow F_Z = F_1(\Gamma) = G/K \longrightarrow F_2(\Gamma) = G/Q
\]

is holomorphic w.r.t. \((D_z, J_1(\Gamma)), J_1(\Gamma)\) and \(J_2(\Gamma)\). The space of the invariant CR structures \((D_z, J)\) on \(M\) such that the projection \(\pi': M \to F_2(\Gamma)\) is holomorphic, is parameterized by the points of the unit disc \(D \in \mathbb{R}^2\). The center of \(D\) corresponds to the CR structure \((D_z, J_1(\Gamma))\) and the other points correspond to the non-standard CR structures. Moreover a CR structure is non-standard if and only if it induces a non-standard CR structure on the fiber \(Q/L\); such induced CR structure is always primitive, with the exceptions of the cases in which \(\Gamma\) is a special CR-graph.

As final remark, we would like to mention that our classification of compact homogeneous CR manifolds have several important corollaries concerning compact cohomogeneity one Kähler manifolds. In particular, such corollaries are an essential tool towards the classification of Kähler-Einstein manifolds in the above class. They will be discussed in a forthcoming paper.
2. Basic facts about CR structures.

Definition 2.1.

1. A CR structure on a manifold \( M \) is a pair \((\mathcal{D}, J)\), where \( \mathcal{D} \subset TM \) is a distribution on \( M \) and \( J \in \text{End} \mathcal{D} \), \( J^2 = -1 \), is a complex structure on \( \mathcal{D} \).

2. A CR structure \((\mathcal{D}, J)\) is called integrable if \( J \) satisfies the following integrability condition:

\[
J([JX,Y] + [X,JY]) \in \mathcal{D},
\]

\[
[JX,JY] - [X,Y] - J([JX,Y] + [X,JY]) = 0 \tag{2.1}
\]

for any pair of vector fields \( X, Y \) in \( \mathcal{D} \).

In the sequel, by CR manifold we will understand a manifold \( M \) with integrable CR structure.

If \((\mathcal{D}, J)\) is a CR structure then the complexification \( \mathcal{D}^\mathbb{C} \subset T^\mathbb{C}M \) of the distribution \( \mathcal{D} \) is decomposed into a sum \( \mathcal{D}^\mathbb{C} = \mathcal{D}^{10} + \mathcal{D}^{01} \) of two mutually conjugated \( J \)-eigendistributions with eigenvalues \( i \) and \(-i\). The integrability condition (2.1) means that these eigendistributions are involutive (i.e. closed under the Lie bracket).

The codimension of a CR structure \((\mathcal{D}, J)\) is defined as the codimension of the distribution \( \mathcal{D} \). Remark that a codimension zero CR structure is the same as a complex structure on a manifold. A codimension one CR structure \((\mathcal{D}, J)\) is also called a CR structure of hypersurface type, because such is the structure which is induced on a real hypersurface of a complex manifold. In this case the distribution \( \mathcal{D} \) can be described locally as the kernel of a 1-form \( \theta \). The form \( \theta \) defines an Hermitian symmetric bilinear form

\[
\mathcal{L}^\theta_q : \mathcal{D}_q \times \mathcal{D}_q \to \mathbb{R}
\]

given by

\[
\mathcal{L}^\theta(v, w) = (d\theta)(v, Jw)
\]

for any \( v, w \in \mathcal{D} \). It is called the Levi form. Remark that the 1-form \( \theta \) is defined up to multiplication by a function \( f \) everywhere different from zero and that \( \mathcal{L}^{f\theta} = f\mathcal{L}^\theta \). In particular, the conformal class of a Levi form depends only on the CR structure.

A CR structure \((\mathcal{D}, J)\) of hypersurface type is called non-degenerate if it has non-degenerate Levi form or, in other words, if \( \mathcal{D} \) is a contact distribution. In this case a 1-form \( \theta \) with \( \ker \theta = \mathcal{D} \) is called contact form.

A smooth map \( \varphi : M \to M' \) of one CR manifold \((M, \mathcal{D}, J)\) into another one \((M', \mathcal{D}', J')\) is called holomorphic map if

a) \( \varphi_* (\mathcal{D}) \subset \mathcal{D}' \);

b) \( \varphi_* (Jv) = J' \varphi_* (v) \) for all \( v \in \mathcal{D} \).

In particular, we may speak about CR transformation of a CR manifold \((M, \mathcal{D}, J)\) as a transformation \( \varphi \) such that \( \varphi \) and \( \varphi^{-1} \) are CR maps. In general, the group of all CR transformations is not a Lie group, but it is a Lie group when \((\mathcal{D}, J)\) is of hypersurface type and it is Levi non-degenerate.
Definition 2.2. A CR manifold \((M, \mathcal{D}, J)\) is called homogeneous if it admits a transitive Lie group \(G\) of CR transformations.

Our aim is to classify compact homogeneous codimension one non-degenerate CR manifolds. The following theorem, which is indeed a consequence of the results in [1], shows that we may identify any such manifold with a quotient space \(G/L\) of a compact Lie group \(G\).

Theorem 2.3. [12] Let \((M, \mathcal{D}, J)\) be a compact non-degenerate CR manifold of hypersurface type. Assume that it is homogeneous, i.e. that there exists a transitive Lie group \(A\) of CR transformations. Then a maximal compact connected subgroup \(G\) of \(A\) acts on \(M\) transitively and one may identify \(M\) with the quotient space \(G/L\) where \(L\) is the stabilizer of a point \(p \in M\).

Now we fix some notations. If the opposite is not stated, we will assume that a CR structure is of hypersurface type, integrable and Levi non-degenerate.

The Lie algebra of a Lie group is denoted by the corresponding gothic letter. For any subset \(A\) of a Lie group \(G\) or of its Lie algebra \(g\), we denote by \(\mathcal{C}_G(A)\) and \(\mathcal{C}_g(A)\) its centralizer in \(G\) and \(g\), respectively. \(Z(G)\) and \(Z(g)\) denote the center of a Lie group \(G\) and a Lie algebra \(g\). By homogeneous manifold \(M = G/L\) we mean a homogeneous manifold of a compact connected Lie group \(G\) with connected stability subgroup \(L\) and such that the action of \(G\) on \(M\) is effective.

3. Compact Homogeneous Contact Manifold.

3.1 Homogeneous contact manifolds of a compact Lie group \(G\).

Let \(M = G/L\) be a homogeneous manifold of a compact Lie group \(G\) with connected stabilizer \(L\).

A 1-form \(\theta \in g^*\) on the Lie algebra \(g\) of \(G\) is called contact form if it is \(\text{Ad}_L\)-invariant and vanishes on \(l = \text{Lie}\, L\). Such form defines a global invariant 1-form \(\theta\) on the manifold \(M\) which is a contact form of the contact distribution \(\mathcal{D} = \ker \theta\). This establishes a 1-1 correspondence between invariant contact structures \(\mathcal{D}\) on \(M\) and contact 1-forms \(\theta \in g^*\) up to a scaling (see e.g.[2]).

Fix now an \(\text{Ad}_G\)-invariant Euclidean metric \(\mathcal{B}\) on \(g\) and denote by \(l^\perp\) the orthogonal complement to \(l\) in \(g\).

The vector \(Z = B^{-1} \circ \theta\) which corresponds to a contact form \(\theta\) is called a contact element of the manifold \(M = G/L\).

It is characterized by the properties that:

1. \(Z \in l^\perp\) and
2. the centralizer \(\mathcal{C}_g(Z) = l \oplus \mathbb{R}Z\).

Hence, we have the following

Proposition 3.1. There exists a natural bijection between invariant contact structures on a homogeneous manifold \(M = G/L\) and contact elements \(Z\) defined up to a scaling.

We will denote by \(\mathcal{D}_Z\) the contact structure on \(M\) defined by a contact element \(Z\). A homogeneous manifold \(M = G/L\) with an invariant contact structure \(\mathcal{D}\) is called homogeneous contact manifold.

Proposition 3.1 implies the following
Corollary 3.2. Let $G/L$ be a homogeneous contact manifold of a compact Lie group $G$ which acts effectively. Then the the center $Z(G)$ of $G$ has dimension 0 or 1.

Moreover, if $Z(G)$ is one dimensional, then any contact element $Z$ has not zero orthogonal projections $Z_g(Z_g')$ on $Z(g)$ and $g' = [g, g]$, and the stability subalgebra $I$ can be written as

$$ I = \{ [Z_g(Z_g')] \}_{Z_g \neq 0} $$

where $\varphi: C_{g'}(Z_{g'}) \to Z(g) \approx \mathbb{R}$ is a non-trivial Lie algebra homomorphism.

Proof. Clearly $C_g(Z) \supset Z(g)$. If $\dim Z(g) \geq 2$ then $I \cap Z(g) \neq \{0\}$ and this contradicts the fact that $G$ acts effectively. The other claims follow immediately. □

Now we associate with a homogeneous contact manifold $(M = G/L, D_Z)$ a flag manifold

$$ F_Z \overset{\text{def}}{=} \text{Ad}_G Z = \text{Ad}_{G'}(Z_{g'}) $$

where $K = C_{G}(Z)$ is the centralizer of the contact element $Z$. We will call $F_Z$ the flag manifold associated to a contact element $Z$.

Note that the contact form $\theta = \mathcal{B} \circ Z$ is a connection (form) in the $S^1$ bundle $\pi : G/L \to F_Z$ and that the corresponding contact structure $D = \ker \theta$ is the horizontal distribution of this connection.

We describe now all homogeneous contact manifolds $(G/L, D_Z)$ with associated flag manifold $F = G/K$ of a semisimple Lie group $G$.

Consider the orthogonal reductive decomposition

$$ g = \mathfrak{k} + \mathfrak{m} $$

associated with the flag manifold $F = G/K$.

We say that an element $Z$ of the center $Z(\mathfrak{k})$ is $\mathfrak{t}$-regular if it generates a closed 1-parametric subgroup of $G$ and the centralizer $C_{G}(Z) = K$.

One can check that if $Z$ is $\mathfrak{t}$-regular, then the subalgebra

$$ I_Z = \mathfrak{t} \cap (Z) \perp $$

generates a closed subgroup, which we denote by $L_Z$. Therefore

Proposition 3.3. Let $F = G/K$ be a flag manifold of a semisimple Lie group $G$. There is a natural 1-1 correspondence

$$ Z \leftrightarrow (G/L_Z, D_Z) $$

between the $\mathfrak{t}$-regular elements $Z \in \mathfrak{g}$ (determined up to a scaling) and the homogeneous contact manifolds $(G/L, D)$ associated flag manifold $F = G/K$.

Proof. The proof is straightforward. □

3.2 Invariant contact structures on a contact manifold $M = G/L$.

Now we describe all invariant contact structures on a given homogeneous manifold $M = G/L$. We will show that generically there is no more then one such structure.
Definition 3.4. A homogeneous manifold $G/L$ is called homogeneous contact manifold of non-special type (respectively, of special type or, shortly, special) if it admits a unique (respectively, more than one) invariant contact structure.

3.2.1 Main examples of special homogeneous contact manifolds.

Let $g$ be a compact semisimple Lie algebra, $h$ a Cartan subalgebra of $g$ and $R$ the root system of the pair $(g^C, h^C)$.

Recall that a root $\alpha \in R$ defines a 3-dimensional regular subalgebra $g^C(\alpha)$ with standard basis given by the root vectors $E_{\alpha}, E_{-\alpha}$ and $H_{\alpha} = [E_{\alpha}, E_{-\alpha}] = \frac{2}{|\alpha|^2} B^{-1} \circ \alpha \quad (3.1)$

verifying the relation $[H_{\alpha}, E_{\pm \alpha}] = \pm 2E_{\pm \alpha}$. Its intersection with $g$ is a 3-dimensional compact subalgebra denoted by $g(\alpha)$. We will call $g(\alpha)$ the subalgebra associated with the root $\alpha$ and denote by $G(\alpha)$ the 3-dimensional subgroup of the adjoint group $G = \text{Int}(g) = \text{Aut}(g)^0$ generated by $g(\alpha)$.

Note that any two such subalgebras are conjugated by an inner automorphism of $g$ if and only if the corresponding roots have the same length.

Fix a system $R^+$ of positive roots of $R$ and put $R^- = -R^+$. The highest root $\mu$ of $R^+$ defines the following gradation of the complex Lie algebra $g^C$:

$$g^C = g_{-2} + g_{-1} + g_0 + g_1 + g_2, \quad (3.2)$$

where

$$g_{-2} = CE_{-\mu}, \quad g_2 = CE_\mu, \quad g_0 = CH_\mu + g_0', \quad g'_0 = C^{g^C}(g(\mu)) \quad (3.3)$$

and $R_\mu = \{ \alpha \in R, \alpha \perp \mu \}$ is the root system of the subalgebra $g_0 = C_g(H_\mu)$.

(3.2) is called the gradation associated with the highest root.

The explicit decomposition (3.2) for any simple complex Lie algebra is given in Table 1 of the Appendix.

Denote by $l = C_g(g(\mu)) = g_0' \cap g$ the centralizer of $g(\mu)$ in $g$ and by $L$ the corresponding connected subgroup of $G$. It is easy to check that $L = C_G(g(\mu))$.

Lemma 3.5. Let $G$ be a compact simple Lie group without center and let $L = C_G(g(\mu))$ be as defined above. Then any non zero vector $Z \in g(\mu)$ is a contact element of the manifold $G/L$. In particular, $G/L$ is a homogeneous contact manifold of special type.

Proof. Observe that $Z \in g(\mu)$ is a contact element if and only if $C_g(Z) = l + \mathbb{R}Z$ and then $g \cdot Z$ is contact for any $g \in G(\mu)$. Since $G(\mu)$ acts transitively on the unit sphere of $g(\mu)$, the Lemma follows from the fact that

$$C_g(iH_\mu) = g_0 \cap g = l + \mathbb{R}(iH_\mu)$$
and hence that $iH_\mu$ is a contact element. □

Remark that the contact manifolds $M = G/L = G/C_G(\mathfrak{g}(\mu))$, with $G$ simple, carry invariant 3-Sasakian structure and they exhaust all homogeneous 3-Sasakian manifolds (see [6]).

3.2.2 Classification of special homogeneous contact manifolds.

The previous examples almost exhaust the class of special homogeneous contact manifolds. In fact, we have the following classification theorem.

**Theorem 3.6.** Let $M = G/L$ be a special homogeneous contact manifold of a compact Lie group $G$. Then the group $G$ is simple and either $L$ is the centralizer of the subalgebra $\mathfrak{g}(\mu)$ associated with the highest root and $M$ is a homogeneous 3-Sasakian manifold or $G = G_2$ and $L$ is the centralizer of the subalgebra $\mathfrak{g}(\nu)$ associated with a short root $\nu$.

**Proof.** We prove first that if $G$ is not semisimple and, hence, dim $Z(\mathfrak{g}) = 1$, then a contact element $Z$ is unique up to a scaling and $M$ is not special. Indeed, we have the decomposition

$$\mathfrak{k} = C_\mathfrak{g}(Z) = \mathfrak{l} \oplus \mathbb{R}Z = \mathfrak{l} + Z(\mathfrak{g})$$

since $Z(\mathfrak{g}) \cap \mathfrak{l} = 0$, by effectivity. The line $\mathbb{R}Z$ is determined uniquely as the orthogonal complement to $\mathfrak{l}$ in $\mathfrak{k} = \mathfrak{l} + Z(\mathfrak{g})$.

Now we may assume that $\mathfrak{g}$ is semisimple. We need the following:

**Lemma 3.7.** Let $\mathfrak{g}$ be compact semisimple and let $\mathfrak{l} \subset \mathfrak{g}$ be a closed subalgebra, which contains no ideal of $\mathfrak{g}$. If there exist two not proportional vectors $Z, Z' \in \mathfrak{l}^\perp$ such that

$$C_\mathfrak{g}(Z) = \mathfrak{l} + \mathbb{R}Z, \quad \mathfrak{l} + \mathbb{R}Z' \subseteq C_\mathfrak{g}(Z'),$$

then $\mathfrak{g}$ is simple and there exists a root $\alpha \in \mathbb{R}$ such that:

1. $\mathfrak{l} = C_\mathfrak{g}(\mathfrak{g}(\alpha))$;
2. $Z, Z' \in \mathfrak{g}(\alpha)$ and $C_\mathfrak{g}(Z') = C_\mathfrak{g}(\mathfrak{g}(\alpha)) + \mathbb{R}Z'$;
3. $C_\mathfrak{g}(\mathfrak{l}) = Z(\mathfrak{l}) + \mathfrak{g}(\alpha)$;
4. for any root $\beta$ which is orthogonal to $\alpha$, $\alpha \pm \beta$ is not a root.

**Proof.** We put $\mathfrak{k} = C_\mathfrak{g}(Z)$ and consider the orthogonal decomposition

$$\mathfrak{g} = \mathfrak{k} + \mathfrak{m} = (\mathfrak{l} + \mathbb{R}Z) + \mathfrak{m}.$$ Denote by $R$ the root system of the complex Lie algebra $\mathfrak{g}^\mathbb{C}$ with respect to a Cartan subalgebra $\mathfrak{h}^\mathbb{C}$ which is the complexification of a Cartan subalgebra $\mathfrak{h}$ of $\mathfrak{k}$. Then the element $Z'$ can be written as

$$Z' = cZ + \sum_{i=1}^{k} c_i E_{\alpha_i},$$

for some root vectors $E_{\alpha_i}$ and constants $c, c_i$. The condition $[\mathfrak{l}, Z'] = 0$ implies $\alpha_i(\mathfrak{h} \cap \mathfrak{l}) = 0$ if $c_i \neq 0$. Since $\mathfrak{h} \cap \mathfrak{l}$ is of codimension one in $\mathfrak{h}$, there exist exactly two (proportional) roots with this property, say $\alpha$ and $-\alpha$. This shows that $\mathfrak{l} \subset$
Moreover, since $Z \in h \cap t^1$, we obtain also that $Z$ is proportional to $H_\alpha = [E_\alpha, E_{-\alpha}]$ and (1) follows. In particular, $g$ must be simple and now (2) is clear. (3) follows from (2).

To prove (4), assume that there is a root $\beta$ which is orthogonal to $\alpha$ and such that $\alpha + \beta$ is a root. Then the vector $E_\beta + E_{-\beta} \in g^C$ does not belong to $l^C = C_g^C(g(\alpha))$, but it is orthogonal to $Z$ (since $Z$ is proportional to $H_\alpha$) and belongs to the centralizer of $Z$: contradiction. □

Now we conclude the proof of Theorem 3.6. Let $G$ be a compact semisimple Lie group and let $Z, Z'$ two non-proportional contact elements for $G/L$. By Lemma 3.7, $G$ is simple and $L = C_G(g(\alpha))$. By direct inspection of the root systems of simple Lie groups, a root $\alpha$ verifies the condition (4) of Lemma 3.7 if and only if it is a long root or if it is a short root in the $G_2$ type system. This concludes the proof. □

3.3 Isotropy representation of a homogeneous contact manifold.

Let $M = G/L$ be a homogeneous contact manifold with invariant contact structure $\mathcal{D}$ associated to a contact element $Z$. Let $g = l + RZ + m$ be the corresponding orthogonal decomposition. Fix a Cartan subalgebra $h$ of $g$ which belongs to $k = l + RZ = Z(l) + l'$ (where $l' = [l, l]$ is the semisimple part of $l$). Then
\[ h = Z(l) + h' = Z(l) + RZ + h', \]
where we denote by $h'$ a Cartan subalgebra of $l'$. Remark that $h(l) = Z(l) + h'$ is a Cartan subalgebra of $l$.

Denote by $R$ (resp. $R_o$) the root system of $g^C$ (resp. $l^C$) w.r.t. the Cartan subalgebra $h^C$ and let $R' = R \setminus R_o$. We will denote by $h(\mathbb{R})$ the standard real form of $h$, spanned by $R$, that is
\[ h(\mathbb{R}) = h \cap B^{-1}(< R >). \]
We put $t = Z(l) \cap h(\mathbb{R})$. Then $Z \in it$ and we may identify
\[ \vartheta = -i\theta = -iB(Z, \cdot) \]
with the corresponding element in $t^* \subset h(\mathbb{R})^* = \text{span}_\mathbb{R}R$.

Consider the decomposition of the $l^C$-module $m^C$ into sum of irreducible $l^C$-modules
\[ m^C = \sum m(\gamma). \quad (3.4) \]
Here, $m(\gamma)$ stands for the irreducible $l^C$-module with highest weight $\gamma \in R'$.

The following Lemma states a well known property of flag manifolds (see e.g. [4] or [3]).
Lemma 3.8. The \( \mathfrak{f}^C \)-modules \( m(\gamma) \) are pairwise not equivalent and, in particular, the decomposition (3.4) is unique. The moduli \( m(\gamma) \) are irreducible also as \( \mathfrak{f}^C \)-modules.

Proof. We only need to check that a module \( m(\gamma) \) is irreducible also as an \( \mathfrak{f}^C \)-module. But it is sufficient to observe that the semisimple parts of \( \mathfrak{f}^C \) and of \( \mathfrak{f}^C \) coincide and to recall that, whenever \( \dim_\mathbb{C} m(\gamma) > 1 \), the semisimple part of \( \mathfrak{f}^C \) acts non-trivially and irreducibly on \( m(\gamma) \). \( \square \)

From Lemma 3.8 we derive the following technical proposition, which will be useful in the following sections.

Proposition 3.9. Let \( M = G/L \) be a homogeneous contact manifold and let \( Z \) be a contact element for \( M \). Assume that \( G \neq G_2 \) or that \( G = G_2 \) and \( \vartheta = -i\mathbb{B} \circ Z \) is not proportional to a short root of \( R \).

Then for any irreducible \( \mathfrak{f}^C \)-module \( m(\gamma) \) there exists at most one distinct \( \mathfrak{f}^C \)-module \( m(\gamma') \) which is isomorphic to \( m(\gamma) \) as \( \mathfrak{f}^C \)-module.

This is the case if and only if the highest weights \( \gamma \) and \( \gamma' \) are \( \vartheta \)-congruent, i.e. \( \gamma' = \gamma + \lambda \vartheta \) for some real number \( \lambda \).

Corollary 3.10. Let \( M \) and \( Z \) as in the Proposition 3.9. Then:

a) if the modules \( m(\gamma), m(\gamma') \) are equivalent as \( \mathfrak{f}^C \)-modules, then for any weight \( \alpha \in R' \) of \( m(\gamma) \), there exists exactly one weight \( \alpha' \in R' \) of \( m(\gamma') \) which is \( \vartheta \)-congruent to \( \alpha \);

b) for any root \( \alpha \in R' \) there exists at most one root \( \alpha' \in R' \) which is \( \vartheta \)-congruent to \( \alpha \), i.e. such that \( \alpha' = \alpha + \lambda \vartheta \) for some real number \( \lambda \neq 0 \).

Proof of Proposition 3.9. Observe that two irreducible \( \mathfrak{f}^C \)-modules \( m(\gamma) \) and \( m(\gamma') \) are isomorphic if and only if their highest weights \( \gamma|_{\mathfrak{h}(i)} \) and \( \gamma'|_{\mathfrak{h}(i)} \) coincide. This occurs if and only if \( \gamma' = \gamma + \lambda \vartheta \) for some \( \lambda \in \mathbb{R} \).

Assume now that there exist three distinct isomorphic \( \mathfrak{f}^C \)-modules \( m(\gamma), m(\gamma') \) and \( m(\gamma'') \). Then \( \tilde{R} = \text{span}_\mathbb{R}(\gamma, \gamma', \gamma'') \cap R \) is a 2-dimensional root system and \( \gamma, \gamma' \) and \( \gamma'' \) belong to the straight line \( \gamma + \mathbb{R} \vartheta \). Checking all 2-dimensional root systems, \( 2A_1, A_2, B_2, G_2 \), we conclude that this is possible only if \( \tilde{R} \) is of type \( B_2 \) or \( G_2 \) and \( \vartheta \) is proportional to a short root. We claim that both these cases cannot occur.

If \( \tilde{R} \) has type \( G_2 \), then \( \tilde{R} = R \) which contradicts to the assumptions.

If \( \tilde{R} \) has type \( B_2 \), one of the roots \( \gamma, \gamma', \gamma'' \) is orthogonal to \( \vartheta \) and this is impossible because

\[ \vartheta \perp \cap R = R_0 = R \setminus R' \]

while \( \gamma, \gamma', \gamma'' \in R' \). \( \square \)

4. General Properties of Compact Homogeneous CR manifolds.

4.1 Infinitesimal description of invariant CR structures.

Let \( (M = G/L, \mathcal{D}_Z) \) be a homogeneous contact manifold of a connected compact Lie group \( G \) with connected stabilizer \( L \) and let

\[ \mathfrak{g} = \mathfrak{l} + \mathbb{R}Z + m \quad (4.1) \]

the associated orthogonal decomposition where \( \mathfrak{f} = C_{\mathfrak{g}}(Z) = \mathfrak{l} + \mathbb{R}Z \).
**Definition 4.1.** A complex subspace \( m^{10} \) of \( m^C \) is called holomorphic if

i) \( m^{10} \cap m^{01} = \{0\} \), where \( m^{01} = \overline{m^{10}} \) and 'bar' denotes the complex conjugation with respect to the real subspace \( g \);

ii) \( m^C = m^{10} + m^{01} \);

iii) \( \mathfrak{f}^C + m^{10} \) is a complex subalgebra of \( \mathfrak{g}^C \).

In the following we will refere to condition iii) as the integrability condition.

Note that if the integrability condition holds, also \( \mathfrak{f}^C + m^{01} \) is a subalgebra. Furthermore, any holomorphic subspace \( m^{10} \) defines an \( \text{ad}_L \)-invariant complex structure \( J \) on \( m \), whose \((+i)-\) and \((-i)-\)eigenspaces are exactly \( m^{10} \) and \( m^{01} \).

**Proposition 4.2.** Let \( (M = G/L, \mathcal{D}_Z) \) be a compact homogeneous contact manifold and \( \mathfrak{g} = \mathfrak{f} + \mathbb{R}Z + m \) be the associated decomposition. Then there exists a natural one to one correspondence between the set of invariant CR structures \((\mathcal{D}_Z, J)\) on \( M \) and the set of holomorphic subspaces \( m^{10} \) of \( m^C \).

**Proof.** Recall that, under the natural identification of \( \mathbb{R}Z + m \) with the tangent space \( T_eLM \), we have that \( m = \mathcal{D}_Z|eL \). Moreover, any invariant CR structure \((\mathcal{D}_Z, J)\) defines a decomposition \( \mathcal{D}_Z^C = \mathcal{D}^{10} + \mathcal{D}^{01} \) into two mutually conjugated invariant integrable distributions. Then one can easily check that the complex subspace \( m^{10} = \mathcal{D}^{10}_{eL} \subset m^C \) is a holomorphic subspace.

Conversely an holomorphic subspace \( m^{10} \) and its conjugate subspace \( m^{01} = \overline{m^{10}} \) are \( \text{ad}_L \)-invariant and also \( \text{Ad}_L \)-invariant since \( L \) is connected. Then they can be extended to two invariant integrable complex distributions \( \mathcal{D}^{10} \) and \( \mathcal{D}^{01} \) such that \( \mathcal{D}^C = \mathcal{D}^{10} + \mathcal{D}^{01} \) with \( \mathcal{D}^{10} \cap \mathcal{D}^{01} = 0 \). Hence they may be considered as eigendistributions of an invariant CR structure \((\mathcal{D}_Z, J)\) on \( M \). \( \square \)

### 4.2 Standard CR structures.

We want to show how to construct an invariant CR structure \((\mathcal{D}_Z, J)\) on a homogeneous contact manifold \( (M = G/L, \mathcal{D}_Z) \) starting from an invariant complex structure \( J \) on the associated flag manifold \( F_Z \).

Let \( F = G/K \) be a flag manifold and let \( \mathfrak{g} = \mathfrak{f} + m \) the associated reductive decomposition. Recall that an invariant complex structure \( J_F \) on \( F \) is associated with a decomposition \( m^C = m^{10} + m^{01} \) such that

\[
a) \quad m^{01} = \overline{m^{10}} \quad ; \quad b) \quad \mathfrak{p} = \mathfrak{f}^C + m^{10} \quad \text{is a subalgebra of} \quad \mathfrak{g}^C. \tag{4.2}
\]

We say that \( m^{10} \) is the holomorphic subspace associated with \( J_F \).

It is known that \( \mathfrak{p} \) is a parabolic subalgebra, with reductive part \( \mathfrak{f}^C \) and nilradical \( m^{10} \). Moreover, we can always choose a system of positive roots \( R^+ \) for \( \mathfrak{g}^C \), such that \( m^{10} \) is generated by root vectors \( E_\alpha \), with \( \alpha \in R^+ \). We say that such system \( R^+ \) is compatible with the complex structure \( J_F \).

Let \( (M = G/L, \mathcal{D}_Z) \) be a homogeneous contact manifold, \( \mathfrak{g} = (1+\mathbb{R}Z) + m = \mathfrak{f} + m \) the corresponding decomposition and \( F_Z = G/K \) the associated flag manifold. Any invariant complex structure \( J_F \) on \( F_Z \) induces an invariant CR structure \((\mathcal{D}_Z, J)\), which is the one corresponding to the same holomorphic subspace \( m^{10} \subset m^C \) as \( J_F \).
Definition 4.3. An invariant CR structure \((\mathcal{D}, J)\) on a homogeneous contact manifold \((M = G/L, \mathcal{D})\), which is induced by an invariant complex structure \(J_F\) on the associated flag manifold \(F = G/K\), is called standard CR structure.

Remark 4.4. Since any flag manifold admits at least one invariant complex structure, we may conclude that any homogeneous contact manifold \((G/L, \mathcal{D})\), with \(G\) compact, admits an invariant CR structure \((\mathcal{D}, J)\).

The following Lemma gives an algebraic characterization of the standard CR structures.

Lemma 4.5. An invariant CR structure \((\mathcal{D}, J)\) on a homogeneous contact manifold \((M = G/L, \mathcal{D})\) is standard if and only if the corresponding complex structure \(J\) on \(m\) is \(\text{Ad}(K)\)-invariant.

Proof. The proof is straightforward. □

Since the description of all invariant complex structures on flag manifolds is well known (see [10], [4], [5], [3]), the problem of classification of the invariant CR structures on compact homogeneous spaces reduces to the description of non-standard invariant CR structures.

The following proposition reduces the problem to the case of \(G\) semisimple.

Proposition 4.6. Let \((M = G/L, \mathcal{D})\) be a contact manifold of a compact Lie group \(G\) with \(\text{dim} Z(G) = 1\). Then any invariant CR structure with underlying distribution \(\mathcal{D}\) is standard.

Proof. It follows immediately from the fact that any \(\text{Ad}(L)\)-invariant decomposition \(m^C = m^{10} + m^{01}\) is clearly also \(\text{Ad}(K)\)-invariant, since \(K = L \cdot Z(G)\). □

4.3 Holomorphic fibering of homogeneous CR manifolds.

Let \((M = G/L, \mathcal{D}, J)\) be a homogeneous CR manifold with a standard CR structure \(J\) associated to a complex structure \(J_F\) on the associated flag manifold \(F = G/K\). Then the natural projection

\[ \pi: G/L \longrightarrow F = G/K \]

is a \(G\)-equivariant holomorphic fibration.

More generally we give the following definition.

Definition 4.7. Let \(M = G/L\) be a homogeneous manifold with invariant CR structure \((\mathcal{D}, J)\).

(1) Any \(G\)-equivariant holomorphic fibering

\[ \pi: M = G/L \longrightarrow F = G/Q \]

of \((M, \mathcal{D}, J)\) over a flag manifold \(F = G/Q\) equipped with an invariant complex structure \(J_F\) is called CRF fibration;

(2) we say that a homogeneous CR manifold \((M = G/L, \mathcal{D}, J)\) is primitive if it doesn’t admit a non-trivial CRF fibration;

(3) a non-primitive homogeneous CR manifold \((M = G/L, \mathcal{D}, J)\), admitting a CRF fibration with typical fiber \(S^1\), is called circular.
Remark that any standard CR structure is circular and that the typical fiber \( Q/L \) of a CRF fibration carries a natural invariant CR structure.

The following Lemma gives a characterization of primitive CR structures.

**Lemma 4.8.** A homogeneous CR manifold \( (G/L, \mathcal{D}, J) \) admits a non-trivial CRF fibration if and only if there exists a proper parabolic subalgebra \( p = r + n \subseteq g^C \) (here \( r \) is a reductive part and \( n \) the nilpotent part) such that

\[
\begin{align*}
  a) \ r &= (p \cap g)^C ; \\
  b) \ t^C + m^{10} \subseteq p ; \\
  c) \ t^C \subseteq r .
\end{align*}
\]

In this case, \( G/L \) admits a CRF fibration with basis \( G/Q \), where \( Q \) is the connected subgroup generated by \( q = r \cap g \).

**Proof.** Suppose that \( (M = G/L, \mathcal{D}, J) \) is non-primitive and let \( \pi : G/L \to G/Q \) be a CRF fibration over a flag manifold \( F = G/Q \) with invariant complex structure \( J_F \). Consider the decompositions associated to \( J \) and \( J_F \)

\[
\begin{align*}
  g &= \mathfrak{l} + \mathbb{R}Z + \mathfrak{m} , \\
  g^C &= m^{10} + m^{01} , \\
  g &= q + m' , \\
  g^C &= m'_{10} + m'^{01} .
\end{align*}
\]

Since \( \pi \) is holomorphic and non-trivial, the subalgebra \( t^C + m^{10} \) is properly contained in the parabolic subalgebra \( p = q^C + m'^{10} \), with reductive part \( q^C = (g \cap p)^C \). Furthermore, since the fiber has positive dimension, \( t \subseteq q \).

Conversely, if \( p = r + n \subseteq g^C \) is a parabolic subalgebra with reductive subalgebra \( r = q^C \), where \( q = p \cap g \), then we may consider the orthogonal decompositions

\[
\begin{align*}
  g &= q + m' , \\
  g^C &= r + m'^C = r + n + n' ,
\end{align*}
\]

where \( n' = n^\perp \cap m'^C \). By the remarks at the beginning of §4.2, there exists a unique invariant complex structure \( J_F \) with associated holomorphic space \( m'^{10} = n \).

Therefore if \( t^C + m^{10} \subseteq p, t \subseteq q \) and \( Q \) is the reductive subgroup generated by \( q \), it is clear that \( \pi : G/L \to G/Q \) is a non-trivial CRF fibration. \( \Box \)

### 4.4 The anticanonical map of a homogeneous CR manifold.

Let \( (M = G/L, \mathcal{D}_Z, J) \) be a homogeneous CR manifolds of a compact Lie group \( G \) and

\[
g = \mathfrak{l} + \mathbb{R}Z + \mathfrak{m} , \\
\mathfrak{m}^C = m^{10} + m^{01} ,
\]

the associated decompositions of \( g \) and of \( m^C \).

To characterize the non-standard invariant CR structures we recall the definition of anticanonical map of a homogeneous CR manifold introduced for the first time in [1]. It is a \( G \)-equivariant holomorphic map

\[
\phi : M = G/L \longrightarrow \text{Gr}_k(g^C)
\]

into the Grassmanian of complex \( k \)-planes, \( k = \dim_C(t^C + m^{01}) \), of \( g^C \) given by

\[
\phi : gL \mapsto \text{Ad}_g(t^C + m^{01}) .
\]
Due to the existence of standard holomorphic $G$-equivariant embedding

$$v: \text{Gr}_k(g^\mathbb{C}) \longrightarrow \mathbb{C}P^N, \quad N = \left(\dim g^\mathbb{C}\right) - 1,$$

$$V = \text{span}(e_1, \ldots, e_k) \mapsto [V] = \mathbb{C}(e_1 \wedge \cdots \wedge e_k),$$

we may consider $\phi$ as a $G$-equivariant map into $\mathbb{C}P^N$. To prove that the map $\phi$ is holomorphic it is sufficient to check that the linear map

$$\phi_*: D_0 = \ker \theta|_{T_0M} = m \longrightarrow T_{[l^C + m^{01}]}\text{Gr}_k(g^\mathbb{C})$$

commutes with the complex structure.

Let $v = X + \bar{X} \in m$, where $X \in m^{10}$. Then

$$\phi_*(v) = \text{ad}_{(X + \bar{X})}([l^C + m^{01}]) = \text{ad}_X([l^C + m^{01}]).$$

Therefore

$$\phi_*(Jv) = \phi_*(iX - i\bar{X}) = \text{ad}_X([l^C + m^{01}]) = i \text{ad}_X([l^C + m^{01}]) = i\phi_*(v).$$

This shows that the map $\phi$ is holomorphic.

Remark that the stabilizer $Q$ of the point $[l^C + m^{01}]$ in $\phi(M) = G/Q$ is the normalizer $Q = N_G([l^C + m^{01}]).$

Now, the following theorem establishes some important properties of the anticanonical map.

**Theorem 4.9.** Let

$$\phi: M = G/L \longrightarrow \text{Gr}_k(g^\mathbb{C})$$

be the anticanonical map of a homogeneous CR manifold $(M = G/L, \mathcal{D}_Z, J)$.

1. If the CR structure is standard, then the image $\phi(M)$ is $G$-equivariantly biholomorphic to the associated flag manifold $F_Z = G/K = \text{Ad}_G Z$ endowed with the complex structure $J_F$ which induces the CR structure $(\mathcal{D}_Z, J)$.

   In this case, $\phi$ is a CRF fibration with fiber $S^1$ and the normalizer in $g$ of $l^C + m^{01}$ is

   $$\mathfrak{k} = N_g([l^C + m^{01}]) = I + \mathbb{R}Z$$

   and it is equal to the stabilizer of the point $[l^C + m^{01}] \in \phi(M)$ in $G$.

2. If the CR structure is not standard, then the image $\phi(M) = G/Q$ is a homogeneous CR manifold with CR structure induced by the complex structure of $\text{Gr}_k(g^\mathbb{C})$ and $\phi: M \rightarrow \phi(M)$ is a finite covering.

**Proof.** We first need the following Lemma, which in fact was proved in [1].
Theorem 4.4. Let \( G/Q = \phi(G/L) \) be the image of the anticanonical map. Then \( \dim Q/L \leq 1 \).

**Proof.** We need to prove that \( \dim q/I \leq 1 \), where \( q = N_{q}(J^{C} + m^{01}) \) is the stability subalgebra of the flag manifold \( G/Q \). Since \( g = I + \mathbb{R}Z + m \), it is sufficient to check that \( q \cap m = 0 \). Let \( v \in q \cap m \). Then

\[
B(Z, [v, J^{C} + m^{01}]) \subset B(Z, J^{C} + m^{01}) = \{0\}
\]

and in particular

\[
\{0\} = B(Z, [v, I + m]) = -B([v, Z], I + m).
\]

This means that \( v \in N_{g}(Z) = \mathfrak{k} = I + \mathbb{R}Z \) and hence that \( v \in \mathfrak{k} \cap m = \{0\} \). \( \square \)

Let us prove (1). Notice that, by Lemma 4.5, if \((D_{Z}, J)\) is standard then \( N_{g}(J^{C} + m^{01}) \supset I + \mathbb{R}Z \). Therefore, from Lemma 4.10, we get that \( N_{g}(I^{C} + m^{01}) = I + \mathbb{R}Z = \mathfrak{k} \) and the image \( \phi(G/L) \) of the anticanonical map coincides with the flag manifold \( F = G/K \).

4.5 Circular CR structures which are non-standard.

As we already pointed out, any standard CR structure is circular. Now we describe the circular CR structures, which are not standard.

Let \((D, J)\) be a circular CR structure on \( G/L \) and let \( Z_{D} \) be a contact element associated to \( D \). Let also \( \pi : G/L \to G/Q \) be the CRF fibration onto the flag manifold \( G/Q \) with fiber \( S^{1} = Q/L \). Notice that, since \( q \) is the isotropy subalgebra of a flag manifold, \( q \) is of the form \( q = I + \mathbb{R}Z_{J} \) for some \( Z_{J} \in C_{g}(I) \cap (I)^{\perp} \).

Since \( \pi \) is holomorphic, \( I^{C} + m^{01} \subset q^{C} + m^{01} \) and \( q^{C} + m^{01} \) is a subalgebra with nilradical \( m^{01} \). This implies that \( q = I + \mathbb{R}Z_{J} \subset N_{g}(I^{C} + m^{01}) \).

By Lemma 4.10, \( \dim N_{g}(I^{C} + m^{01}) \leq \dim I + 1 \) and therefore \( q = N_{g}(I^{C} + m^{01}) \). In particular, the CR structure is standard if and only if \( q = \mathfrak{k} \), i.e. if and only if \( \mathbb{R}Z_{J} = \mathbb{R}Z_{D} \).

If \( G/L \) is a contact manifold of non-special type, then \( \dim C_{g}(I) \cap (I)^{\perp} = 1 \) and hence \( \mathbb{R}Z_{J} = \mathbb{R}Z_{D} \); in particular any circular CR structure is standard.

If \( G/L \) is a contact manifold of special type, the class of all invariant CR structures is explicitly classified in §5. From that classification, the following description of all circular CR structures is immediately obtained.
Theorem 4.11. Let $M = G/L$ be a homogeneous contact manifold of a compact Lie group $G$. Then $M = G/L$ admits an invariant non-standard circular CR structure $(\mathcal{D}, J)$ if and only if $M = SU_\ell/U_{\ell-2}$ for $\ell \geq 2$.

Moreover, any invariant non-standard CR structure $(\mathcal{D}, J)$ on $M = SU_\ell/U_{\ell-2}$ is circular.

We refer to Theorem 5.1 for an explicit description of the non-standard circular CR structures on $M = SU_\ell/U_{\ell-2}$.

5. Classification of CR structures on special contact manifolds.

We describe here all invariant CR structures $(\mathcal{D}_Z, J)$ on a special contact manifold $G/L$. Recall that in this case $G$ is simple and $L = C_G(\mathfrak{g}(\alpha))$, by Theorem 3.6, where either $\alpha = \mu$ is the highest root or $G = G_2$ and $\alpha = \nu$ is a short root.

We have the following orthogonal decomposition of $\mathfrak{g}$

$$\mathfrak{g} = \mathfrak{l} + \mathbb{R}\mathfrak{z} + \mathfrak{m} = \mathfrak{l} + \mathfrak{a} + \mathfrak{n},$$

where $\mathfrak{a} = \mathfrak{g}(\alpha)$ is the 3-dimensional subalgebra associated with the root $\alpha$, $Z = iH_\alpha \subset \mathfrak{a}$ and $\mathfrak{l} = C_\mathfrak{g}(\mathfrak{a})$ is its centralizer.

Let $(\mathcal{D}, J)$ be an invariant CR structure on $G/L$ which is determined by the contact element $Z = iH_\alpha$ and by the decompositions

$$\mathfrak{m}^C = \mathfrak{m}^{10} + \mathfrak{m}^{01} = \mathfrak{a}^{10} + \mathfrak{n}^{10} + \mathfrak{a}^{01} + \mathfrak{n}^{01},$$

where $\mathfrak{a}^{10} = \mathfrak{a}^C \cap \mathfrak{m}^{10}$, $\mathfrak{n}^{10} = \mathfrak{n}^C \cap \mathfrak{m}^{10}$ and $\mathfrak{m}^{01} = \mathfrak{a}^{01} + \mathfrak{n}^{01} = \overline{\mathfrak{m}^{10}}$.

Since $\mathfrak{a}^C \simeq \mathfrak{sl}_2(\mathbb{C})$ and $\mathfrak{a}^{10} + \mathfrak{a}^{01}$ is the orthogonal complement to $C \mathfrak{z}$ in $\mathfrak{a}^C$, we can write $\mathfrak{a}^{10} = C \mathfrak{z}'$, for some $\mathfrak{z}' \in \mathfrak{m}^C \cap \mathfrak{a}^C$.

Note that a regular element $X$ of $\mathfrak{a}^C$ (up to rescaling) can be always identified with $iH_\alpha$, where $\alpha$ is a root of $\mathfrak{g}^C$ with respect to some Cartan subalgebra $\mathfrak{h}$ of $\mathfrak{g}^C$ and such that $\mathfrak{a} = \mathfrak{g}(\alpha)$. In particular, since any contact element $Z$ of $\mathfrak{g}$ is a regular element for $\mathfrak{a}^C$, it can be always identified with $iH_\alpha$.

If $\alpha = \mu$ is the highest root, the eigenspace decomposition of $\text{ad}_{H_\alpha}$ gives the gradation

$$\mathfrak{g}^C = \mathfrak{g}^{\mu-2} + \mathfrak{g}^{-1} + \mathfrak{g}^{0} + \mathfrak{g}^{1} + \mathfrak{g}^{2},$$

which is described in (3.3) and Table 1. Table 1 shows that for $\mathfrak{g}^C \neq A_\ell$, the $\mathfrak{g}_0$-moduli $\mathfrak{g}_{\pm 1}$ are irreducible, their dimension is $\dim_{\mathbb{C}} \mathfrak{g}_{\pm 1} = 1/2 \dim_{\mathbb{C}} \mathfrak{n}^C$ and

$$[\mathfrak{g}_{\pm 1}, \mathfrak{g}_{\pm 1}] = \mathfrak{g}_{\pm 2}.$$  

If $\mathfrak{g}^C = A_\ell$, each $\mathfrak{g}_0$-module $\mathfrak{g}_{\pm 1}$ decomposes into two non-equivalent irreducible $\mathfrak{g}_0$-moduli: $\mathfrak{g}_{\pm 1} = \mathfrak{g}_{\pm 1}^{(1)} + \mathfrak{g}_{\pm 1}^{(2)}$. Moreover, the following relations hold:

$$[\mathfrak{g}_{\pm 1}^{(i)}, \mathfrak{g}_{\pm 1}^{(j)}] = \{0\} = [\mathfrak{g}_{-1}^{(i)}, \mathfrak{g}_{-1}^{(j)}], \quad [\mathfrak{g}_{-1}^{(i)}, \mathfrak{g}_{-1}^{(j)}] = \mathfrak{g}_2, \quad [\mathfrak{g}_{-1}^{(i)}, \mathfrak{g}_{-1}^{(j)}] = \mathfrak{g}_{-2},$$

$$[\mathfrak{g}_{1}^{(i)}, \mathfrak{g}_{-2}] = \mathfrak{g}_{1}^{(j)}, \quad [\mathfrak{g}_{-1}^{(i)}, \mathfrak{g}_{2}] = \mathfrak{g}_{1}^{(j)}, \quad \overline{\mathfrak{g}_{1}^{(i)}} = \mathfrak{g}_{-1}^{(i)} (i \neq j).$$
The moduli $g^{(i)}$ and $g^{(j)}$ ($i \neq j$) are isomorphic as $g_0$-moduli and, for both values of $i$, $\dim \mathbb{C} g^{(i)}_{\pm 1} = 1/4 \dim \mathbb{C} n^C$.

When $g^C = G_2$ and $\alpha = \nu = \varepsilon_1$ is a short root, the eigenspace decomposition of $H_\nu$ operator $ad_{H_\nu}$ defines the following gradation of $g^C$:

$$g^C = g_{-3} + g_{-2} + g_{-1} + g_0 + g_1 + g_2 + g_3,$$

where

$$
g_0 = g'_0 + \mathbb{C}H_\nu, \quad g'_0 = C_{g^C}(g(\nu)) = E_{\pm(\varepsilon_2 - \varepsilon_3)}, H_{\varepsilon_2 - \varepsilon_3},$$

$$g_2 = \mathbb{C}E_{\varepsilon_1}, \quad g_{-2} = \mathbb{C}E_{-\varepsilon_1}, \quad g^C(\nu) = g_2 + g_{-2} + \mathbb{C}H_{\varepsilon_1},$$

$$g_1 = E_{-\varepsilon_3}, E_{-\varepsilon_2}, \quad g_3 = E_{\varepsilon_1 - \varepsilon_3}, E_{\varepsilon_1 - \varepsilon_2},$$

$$g_{-i} = \overline{g_i} \quad \text{for} \quad i = 1, 3.$$  \hspace{1cm} (5.8)

(see Appendix for notation).

Note that all subspaces $g_j$ are irreducible $g_0$-moduli and that the moduli $g_j$, $j = \pm 1, \pm 3$, are equivalent $g_0$-moduli. Furthermore, $[g_{\pm 1}, g_{\pm 1}] = g_{\pm 2}$ and $[g_{\pm 3}, g_{\pm 3}] = \{0\}$.

The following Theorem gives the complete classification of the invariant CR structures on special contact manifolds.

**Theorem 5.1.** Let $(M = G/L, D_Z)$ be a special contact manifold. Then:

a) if $G \neq SU_{\ell+1}$, there exists (up to a sign) a unique invariant CR structure $(D_Z, J)$, and it is the standard one.

b) if $G = SU_2$ and hence $M = SU_2$, there exists a 1-1 correspondence between the invariant CR structures (determined up to a sign) and the points of the unit disc

$$D = \{ t \in \mathbb{C}, \ |t| < 1 \}.$$  \hspace{1cm} (5.9)

Under the identification $Z = iH_\alpha$, a point $t \in D$ corresponds to the CR structure $(D, J_t)$ with the holomorphic subspace

$$m^{10} = \mathbb{C}(E_{\alpha} + tE_{-\alpha}).$$  \hspace{1cm} (5.10)

The CR structure $(D_Z, J_t)$ is standard if and only if $t = 0$.

c) if $G = SU_\ell$, $\ell > 2$, and hence $M = SU_\ell/U_{\ell-2}$, the set of all invariant CR structures (determined up to a sign) consists of:

- c.1) the standard CR structure $(D_Z, J^{(0)})$, induced by the invariant complex structure $J^{(0)}$ on $F_Z = SU_{\ell}/T^2 \cdot SU_{\ell-2}$, which is the natural complex structure of the twistor space of the Wolf space $G_{2}(\mathbb{C}^4) = SU_\ell/S(U_2 \cdot U_{\ell-2})$;

- c.2) three families $(D_Z, J_t)$, $(D_Z, J'_t)$ and $(D_Z, J''_t)$ of invariant CR structures, parameterized by the points of the unit disc $D$. Under the identification $Z = iH_\mu$, the CR structures $(D_Z, J_t)$, $(D_Z, J'_t)$ and $(D_Z, J''_t)$ have the following holomorphic subspaces

$(\text{for } J_t)$

$$m^{10} = \mathbb{C}(E_{\mu} + tE_{-\mu}) + g^{(1)}_1 + g^{(2)}_{-1},$$  \hspace{1cm} (5.11)
Let $G/L$, manifold (5.2), which correspond to an integrable CR structure, for each special contact manifold (5.3).

The proof of Theorem 5.1 reduces to classification of the decompositions (5.2), which correspond to an integrable CR structure, for each special contact manifold (5.3). For any decomposition (5.2), the subspace $\mathfrak{a}^{10}$ can be expressed as $\mathfrak{a}^{10} = \mathbb{C}Z'$ for some suitable $Z' \in \mathfrak{a}^\mathbb{C}$. Therefore we have to cases:

1. $Z'$ is a regular element of $\mathfrak{a}^\mathbb{C}$;
2. $Z'$ is a non-regular (hence nilpotent) element of $\mathfrak{a}^\mathbb{C} \cong \mathfrak{sl}_2(\mathbb{C})$.

Corollary 5.2. Let $(M = G/L, \mathcal{D}_Z)$ be a special contact manifold with $G = SU_\ell$.

(1) If $M = SU_2$, then $(M, \mathcal{D}_Z)$ admits (up to sign) only one standard CR structure and one family of non-standard CR structures, parameterized by the punctured unit disc $D \setminus \{0\} \subset \mathbb{C}$; any non-standard CR structure is circular and the anti-canonical map $\phi : M \rightarrow \phi(M)$ is a finite covering.

(2) If $M = SU_\ell/U_{\ell-2}$, $\ell > 2$, then $(M, \mathcal{D}_Z)$ admits (up to a sign) exactly three standard CR structures (namely $(\mathcal{D}_Z, J_t^0)$, $(\mathcal{D}_Z, J_t)$ and $(\mathcal{D}_Z, J_t')$) that are induced by three invariant complex structures of the corresponding flag manifold $F_Z = SU_\ell/T^2 \cdot SU_{\ell-2}$, plus three families $(\mathcal{D}_Z, J_t^0)$, $(\mathcal{D}_Z, J_t)$ and $(\mathcal{D}_Z, J_t')$ of non-standard CR structures, parameterized by the points of the punctured unit disc $t \in D \setminus \{0\}$; any non-standard CR structure $(\mathcal{D}_Z, J_t^0)$ is primitive, while the CR structures $(\mathcal{D}_Z, J_t)$ and $(\mathcal{D}_Z, J_t')$ are circular; furthermore, each CR structure $(\mathcal{D}_Z, J_t)$ or $(\mathcal{D}_Z, J_t')$ admits also a CRF fibration

$$\pi : M = SU_\ell/U_{\ell-2} \rightarrow Gr_2(\mathbb{C}^\ell) = SU_\ell/S(U_2 \times U_{\ell-2})$$

with fiber $SO_3$ over the Wolf space $Gr_2(\mathbb{C}^\ell)$ equipped with its (unique up to a sign) complex structure; finally, for any non-standard CR structure, the anti-canonical map $\phi : M \rightarrow \phi(M)$ is a finite covering.

Remark 5.3. The complex structures $J_0$ and $J_0'$ on $F_Z$ coincide on the fibers of the twistor fibration $\pi : F_Z \rightarrow Gr_2(\mathbb{C}^\ell)$ but are projected into two opposite complex structures of $Gr_2(\mathbb{C}^\ell)$.

Proof. The proof of Theorem 5.1 reduces to classification of the decompositions (5.2), which correspond to an integrable CR structure, for each special contact manifold $(G/L, \mathcal{D}_Z)$. For any decomposition (5.2), the subspace $\mathfrak{a}^{10}$ can be expressed as $\mathfrak{a}^{10} = \mathbb{C}Z'$ for some suitable $Z' \in \mathfrak{a}^\mathbb{C}$. Therefore we have to cases:

1. $Z'$ is a regular element of $\mathfrak{a}^\mathbb{C}$;
2. $Z'$ is a non-regular (hence nilpotent) element of $\mathfrak{a}^\mathbb{C} \cong \mathfrak{sl}_2(\mathbb{C})$. 
Case (1):
First of all we show that this case may occur only if \( \mathfrak{g} = \mathfrak{su}_t \).
Consider first \( \mathfrak{a} = \mathfrak{g}(\mu) \), with \( \mu \) long root of the simple group \( G \). Since \( Z' \) is regular, we may assume that \( Z' = iH_\mu \) and we may consider the corresponding graded decomposition \( (5.3) \). Recall that \( \mathfrak{f}^C = C_\mathfrak{g}(\mathfrak{g}(\mu)) = \mathfrak{g}_0' \).
Hence the subalgebra \( \mathfrak{b} = \mathfrak{f}^C + \mathfrak{m}^{10} \) is contained in
\[
\mathfrak{f}^C + \mathfrak{m}^{10} = \mathfrak{g}_0' + \mathfrak{a}^{10} + \mathfrak{n}^{10} = \mathfrak{g}_0' + \mathbb{C}H_\mu + \mathfrak{n}^{10} = \mathfrak{g}_0 + \mathfrak{n}^{10} \subset \mathfrak{g}_0 + \mathfrak{g}_1 + \mathfrak{g}_{-1}
\]
since \( \mathfrak{n}^C \subset \mathfrak{g}_1 + \mathfrak{g}_{-1} \), being orthogonal to \( \mathfrak{a}^C = \mathbb{C}H_\mu + \mathfrak{g}_2 + \mathfrak{g}_{-2} \). In case \( \mathfrak{g}^C \neq A_t \), \( \mathfrak{g}_1 \) and \( \mathfrak{g}_{-1} \) are irreducible \( \mathfrak{g}_0 \)-modules and hence either \( \mathfrak{g}_1 \) or \( \mathfrak{g}_{-1} \) is included in \( \mathfrak{n}^{10} \). However \([\mathfrak{g}_1, \mathfrak{g}_1] = \mathfrak{g}_2 \) and \([\mathfrak{g}_{-1}, \mathfrak{g}_{-1}] = \mathfrak{g}_{-2} \), and hence there is no subalgebra \( \mathfrak{b} \) of \( \mathfrak{g}_0 + \mathfrak{g}_1 + \mathfrak{g}_{-1} \) which contains \( \mathfrak{g}_0 \) properly. Hence \( \mathfrak{g}^C = A_t \). In this case, each \( \mathfrak{g}_\pm \) decomposes into two not equivalent irreducible \( \mathfrak{g}_0 \)-moduli \( \mathfrak{g}_\pm^{(i)} \), \( i = 1, 2 \), of dimension equal to \( 1/4 \dim \mathbb{C} \mathfrak{n}^C \), which verify \( (5.5) \) and \( (5.6) \). Like before it is easy to check that the \( \mathfrak{g}_0 \)-moduli decomposition of \( \mathfrak{n}^{10} \) has the form \( \mathfrak{n}^{10} = \mathfrak{g}_1^{(i)} \oplus \mathfrak{g}_{-1}^{(j)} \) for some choice of \( i \) and \( j \). If \( i = j = 1 \), then \( \mathfrak{n}^{10} = \mathfrak{n}^{10} = \mathfrak{g}_1^{(1)} + \mathfrak{g}_{-1}^{(1)} = \mathfrak{n}^{10} \) and this contradicts the condition \( \mathfrak{n}^{10} \cap \mathfrak{n}^{10} = \{0\} \). A similar contradiction arises when \( i = j = 2 \).
In conclusion, if \( \alpha = \mu \) is a long root, then \( \mathfrak{g}^C = A_t \) and for any fixed \( \mathfrak{g}^{10} \) there exist at most two CR structures, i.e., those corresponding to the following two possibilities for \( \mathfrak{n}^{10} \):
\[
\mathfrak{n}^{10} = \mathfrak{g}_1^{(1)} + \mathfrak{g}_{-1}^{(2)} , \quad \mathfrak{n}^{10} = \mathfrak{g}_1^{(2)} + \mathfrak{g}_{-1}^{(1)} . \quad (5.14)
\]
It remains to consider the case in which \( G = G_2 \) and \( \mathfrak{a} = \mathfrak{g}(\nu) \), with \( \nu \) short root of \( \mathfrak{g}^C \). We assume that \( Z' = iH_\nu \) and we consider the corresponding graded decomposition \( (5.7) \).
Then \( \mathfrak{f}^C + \mathfrak{m}^{10} \) is contained in
\[
\mathfrak{f}^C + \mathfrak{m}^{10} = \mathfrak{f}^C + \mathfrak{a}^{10} + \mathfrak{n}^{10} = \mathfrak{g}_0' + \mathbb{C}H_\nu + \mathfrak{n}^{10} \subset \mathfrak{g}_0 + \mathfrak{g}_1 + \mathfrak{g}_{-1} + \mathfrak{g}_3 + \mathfrak{g}_{-3}
\]
because \( \mathfrak{n}^C \) is orthogonal to \( \mathfrak{a}^C = \mathbb{C}H_\nu + \mathfrak{g}_2 + \mathfrak{g}_{-2} \). Since \( \mathfrak{f}^C + \mathfrak{m}^{10} = \mathfrak{g}_0' + \mathfrak{n}^{10} \) is a subalgebra and \( \dim \mathbb{C} \mathfrak{g}_{\pm} = \dim \mathbb{C} \mathfrak{g}_{\pm} = \frac{1}{2} \dim \mathbb{C} \mathfrak{n}^{10} \), \( \mathfrak{n}^{10} \) contains two of the four irreducible \( \mathfrak{g}_0 \)-moduli \( \mathfrak{g}_{\pm} \) and \( \mathfrak{g}_{\pm} \). The only possibility for \( \mathfrak{n}^{10} \), so that \( \mathfrak{g}_0 + \mathfrak{n}^{10} \) is a subalgebra, is \( \mathfrak{n}^{10} = \mathfrak{g}_{-3} + \mathfrak{g}_3 \). This implies that \( \mathfrak{n}^{10} = \mathfrak{n}^{10} = \mathfrak{g}_{-3} + \mathfrak{g}_3 = \mathfrak{n}^{10} \) and it contradicts the condition \( \mathfrak{m}^{10} \cap \mathfrak{m}^{10} = \{0\} \).
Now it remains to classify the invariant CR structures on \( (SU_t/U_{t-2}, D_Z) \).
For the following part of the proof, it is more convenient to identify the contact element \( Z \) (and no longer \( Z' \)) with \( iH_\mu \). We also consider the decomposition \( (5.3) \) determined by \( Z = iH_\mu \).
Since \( Z' \) is a regular element which is orthogonal to \( Z = iH_\mu \), it is (up to a factor) of the form
\[
Z' = E_\mu + tE_{-\mu} , \quad |t| \neq 0 . \quad (5.15)
\]
Exchanging \( \mathfrak{a}^{10} \) with \( \overline{\mathfrak{a}}^{10} \), if necessary (which corresponds to changing sign to the complex structure), we may assume that \( 0 < |t| \leq 1 \).
Since \( a^{10} \cap a^{01} = \{0\} \) and hence \( E_\mu + tE_{-\mu} \) and \( \bar{t}E_\mu + E_{-\mu} \) are linearly independent, \( t \) verifies the condition
\[
\det \begin{bmatrix} 1 & t \\ t & 1 \end{bmatrix} = 1 - |t|^2 \neq 0 \tag{5.16}
\]
and therefore \( t \in D \setminus \{0\} = \{0 < |t| < 1\} \).

We claim that for any point \( t \in D \setminus \{0\} \) there exist exactly three invariant CR structures, whose associated subspace \( a^{10} \) is equal to \( \mathbb{C}(E_\mu + tE_{-\mu}) \). In fact, one can check that the only \( g'_0 \)-invariant subspaces \( m^{10} \) of \( \mathbb{C}(E_\mu + tE_{-\mu}) \) that properly contain \( g_1 + g_{-1} \), which verify (i) and (ii) of Definition 4.1, are either (5.11), (5.12) or a subspace of the form
\[
m^{10} = \mathbb{C}(E_\mu + tE_{-\mu}) + (g_1^{(1)} + sg_{-1}^{(2)}) + (g_1^{(2)} + sg_{-1}^{(1)}) \tag{5.17}
\]
for some coefficient \( s \). One can also check that the subspaces (5.11) and (5.12) verify also the integrability condition, while (5.17) satisfies the integrability condition if and only if \( t = s^2 \). This proves that (5.11), (5.12) and (5.13) are the only holomorphic subspaces of \( m^C \) containing \( \mathbb{C}(E_\mu + tE_{-\mu}) \). In particular, they define three distinct invariant CR structures, which we denote by \( (D_Z, J_t), (D_Z, J'_t) \) and \((D_Z, J_t^{(0)})\).

If \( \ell = 2 \) and hence \( M = SU_2 \), then \( n = \{0\} \) and the three CR structures \( (D_Z, J_t), (D_Z, J'_t) \) and \((D_Z, J_t^{(0)}) \) coincide for any \( t \).

Since for any \( t \neq 0 \) the holomorphic subspaces \( m^{10} \) and \( m^{01} \) are not \( ad_Z \)-invariant, any CR structure \( (D_Z, J_t), (D_Z, J'_t) \) or \((D_Z, J_t^{(0)}) \) \((t \neq 0) \) is non-standard by Lemma 4.5.

**Case (2):**

Since \( Z' \) is not regular, it is a nilpotent element of \( a^C = \mathfrak{sl}_2(\mathbb{C}) = \mathfrak{g}^C(\alpha) \). Then we may always choose a Cartan subalgebra \( CH_\alpha \) of \( a \) so that \( Z' \in CE_\alpha \). Furthermore, since the contact element \( Z \) is orthogonal to \( a^{10} + a^{01} = CE_\alpha + \overline{CE_\alpha} = CE_\alpha + CE_{-\alpha} \), we may assume (after rescaling) that \( Z = iH_\alpha \).

Consider first that \( \alpha = \mu \) is a long root of \( G \) and take the gradation (5.3) of \( \mathfrak{g}^C \) determined with \( H_\mu \). Then \( \mathfrak{g}_2 = \mathbb{C}Z' = a^{10} \) and hence
\[
\mathfrak{g}^C + m^{10} = g'_0 + g_2 + n^{10} \subset g'_0 + g_2 + g_1 + g_{-1}.
\]
Assume that \( \mathfrak{g}^C \neq A_\ell \). Then the \( g'_0 \)-moduli \( \mathfrak{g}_{\pm 1} \) are irreducible and \([g_{\pm 1}, g_{\pm 1}] = g_{\pm 2}\). Hence the only subalgebra of \( g'_0 + g_2 + g_1 + g_{-1} \), which properly contains \( g'_0 + g_2 \), is \( g'_0 + g_1 + g_2 \). Hence \( m^{10} = g_1 + g_2 \).

Vice versa, \( m^{10} = g_1 + g_2 \) is a holomorphic subspace of \( \mathfrak{g}^C = (\mathfrak{g}^C + CZ')^\perp = g_0^\perp \) and hence it corresponds to an invariant CR structure on \((G/L, D_Z)\). Since \( Z = iH_\mu \in N_0(g'_0 + g_{-1} + g_{-2}) = N_0((\mathfrak{g}^C + m^{01})^\perp) \), this CR structure is standard.

Assume now that \( \mathfrak{g}^C = A_\ell \) and again consider the decomposition (5.3) determined by \( Z = iH_\mu \). Since \( \dim_{\mathbb{C}} g_{\pm 1}^{(i)} = 1/4 \dim_{\mathbb{C}} n^C \), the \( g'_0 \)-module \( n^{10} \) can be written in one of the following five forms:

1) \( n^{10} = (g_{1}^{(1)})_\phi + (g_{-1}^{(1)})_\psi \),
2) \( n^{10} = g_{1}^{(1)} + g_{-1}^{(2)} \),
3) \( n^{10} = g_{1}^{(2)} + g_{-1}^{(1)} \),
4) \( n^{10} = g_1 \),
5) \( n^{10} = g_{-1} \).
where \( \varphi : \mathfrak{g}_1^{(1)} \to \mathfrak{g}_1^{(2)} \) and \( \psi : \mathfrak{g}_1^{(1)} \to \mathfrak{g}_1^{(2)} \) are two \( \mathfrak{g}_0 \)-equivariant homomorphisms and where \( (\mathfrak{g}_1^{(1)})_\varphi \) and \( (\mathfrak{g}_1^{(1)})_\psi \) denote the subspaces of the form

\[
(\mathfrak{g}_1^{(1)})_\varphi = \{ X + \varphi(X) : X \in \mathfrak{g}_1^{(1)} \}, \quad (\mathfrak{g}_1^{(1)})_\psi = \{ X + \psi(X) : X \in \mathfrak{g}_1^{(1)} \}.
\]

Case 5) cannot occur because in that case \([n^{10}, n^{10}] = \mathfrak{g}_-2\) and this contradicts the fact that \( \mathfrak{g}_0^0 + n^{10} + \mathfrak{g}_2 \) is a subalgebra.

Also case 1) may not occur. In fact, \( \varphi \) is either trivial or an isomorphism. In case \( \varphi \) is an isomorphism, for any \( 0 \neq X \in \mathfrak{g}_1^{(1)} \), it is possible to find an element \( Y \in \mathfrak{g}_-2 \) so that \([\varphi(X), Y] = 0\) is non-trivial and belongs to \( \mathfrak{g}_-2 \). Hence,

\[
[X + \varphi(X), Y + \psi(Y)] \equiv [\varphi(X), Y] \in \mathfrak{g}_-2.
\]

This gives a contradiction with the fact that \( \mathfrak{g}_0^0 + n^{10} + \mathfrak{g}_2 \) is a subalgebra and the claim is proved.

For the cases 2), 3) and 4), \( m^{10} \) equals one of the following three subspaces

\[
\mathfrak{g}_1^{(1)} + \mathfrak{g}_1^{(2)} + \mathfrak{g}_2, \quad \mathfrak{g}_1^{(2)} + \mathfrak{g}_-1 + \mathfrak{g}_2 + \mathfrak{g}_1 + \mathfrak{g}_3
\]

and one can check that any of them is a holomorphic subspace.

By Proposition 4.2, they determine three distinct CR structures denoted by \((\mathcal{D}, J)\), \((\mathcal{D}, J')\) and \((\mathcal{D}, J^{(0)})\), respectively. For any of the three subspaces \((5.18)\), the normalizer \( N_\mathfrak{g}(\mathcal{C} + m^{10}) \) contains \( \mathfrak{g}_0 \cap \mathfrak{g} = \mathfrak{t} + \mathbb{R} Z \) and hence the corresponding CR structures are standard.

Finally, observe that \((\mathcal{D}, J^{(0)})\) is induced by the invariant complex structure \( J_F \) on the flag manifold \( F_Z = SU_l/T^2 \cdot SU_{l-2} \) which is associated to the following black-white Dynkin graph

\[
\bullet \cdots \circ \circ \circ \bullet
\]

and which is the invariant complex structure of the twistor space of the Wolf space \( Gr_2(C^l) = SU_l/S(U_l \cdot U_{l-2}) \); moreover, the subspace of \( J^{(0)} \) coincides with the subspace given in \((5.13)\) for \( t = 0 \); on the other hand, the subspaces of \( J \) and \( J' \) are the subspaces given in \((5.11)\) and \((5.12)\) for \( t = 0 \). All corresponding CR structures coincide if \( M = SU_2 \).

It remains to consider the case in which \( G = G_2 \) and \( a = \mathfrak{g}(\nu) \), where \( \nu \) is a short root. Consider the decomposition \((5.7)\) determined by \( H_\nu \) so that \( \mathbb{C} Z' = \mathbb{C} E_\nu = \mathfrak{g}_2 \).

As before, we identify \( Z \) with \( iH_\nu \). We have

\[
\mathcal{C} + m^{10} = \mathfrak{g}_0' + a^{10} + n^{10} \subset \mathfrak{g}_0' + \mathfrak{g}_2 + \mathfrak{g}_-1 + \mathfrak{g}_1 + \mathfrak{g}_-3 + \mathfrak{g}_3
\]
because \( n^C \) is orthogonal to \( a^C = \mathbb{C}H_\nu + \mathfrak{g}_{-2} + \mathfrak{g}_2 \). We claim that \( \mathfrak{g}_3 \subset n^{10} \). In fact, for any element \( X \in n^{10} \) consider the decomposition

\[
X = X_{-3} + X_{-1} + X_1 + X_3, \quad X_i \in \mathfrak{g}_i.
\]

Then, one of the four vectors \( X, X' = [E_\nu, X], X'' = [E_\nu, [E_\nu, X]], X''' = [E_\nu, [E_\nu, [E_\nu, X]]] \) is a non-trivial element of \( \mathfrak{g}_3 \) and it belongs to \( n^{10} \). Since \( \mathfrak{g}_3 \) is \( g_0' \)-irreducible, the claim follows.

Similarly, we claim that \( \mathfrak{g}_1 \subset n^{10} \). To prove this, take any element \( X \in n^{10} \) which has a decomposition of the form

\[
X = X_{-3} + X_{-1} + X_1, \quad X_i \in \mathfrak{g}_i.
\]

Then, either \( X \) or \( X' = [E_\nu, X] \) or \( X'' = [E_\nu, [E_\nu, X]] \) is a non-trivial element of \( \mathfrak{g}_1 + \mathfrak{g}_3 \), with non-vanishing projection on \( \mathfrak{g}_1 \). This implies that \( \mathfrak{g}_1 \cap n^{10} \neq \{0\} \) and hence that \( \mathfrak{g}_1 \subset n^{10} \). Since \( \text{dim}_C(\mathfrak{g}_1 + \mathfrak{g}_3) = \text{dim}_C n^{10} \), we conclude that \( n^{10} = \mathfrak{g}_1 + \mathfrak{g}_3 \) and that \( n^{10} = \mathfrak{g}_1 + \mathfrak{g}_2 + \mathfrak{g}_3 \). Indeed, since \( \mathfrak{t}^C + \mathfrak{g}_1 + \mathfrak{g}_2 + \mathfrak{g}_3 \) is always a subalgebra, there exists an integrable CR structure whose associated holomorphic subspace is \( \mathfrak{m}^{10} = \mathfrak{g}_1 + \mathfrak{g}_2 + \mathfrak{g}_3 \). Furthermore, \( N_{\mathfrak{g}}(\mathfrak{t}^C + \mathfrak{m}^{10}) \) contains \( Z = iH_\nu \) and hence this CR structure is standard. \( \square \)

**Proof of Corollary 5.2.** (1) By Theorem 5.1, it remains only need to check that any non-standard CR structure on \( M = SU_2 \) is circular and that the associated anti-canonical map is a finite covering.

By (5.10), the CR structure \( (D_Z, J) \) is non-standard if and only if the corresponding holomorphic subspace is of the form \( \mathfrak{m}^{10} = \mathbb{C}(E_\alpha + tE_{-\alpha}) \) with \( 0 < |t| < 1 \). Since \( \mathfrak{t}^C = \mathfrak{t}^C_2(\mathbb{C}) \) and any parabolic subalgebra \( \mathfrak{p} \) which contains \( \mathfrak{m}^{10} \) verifies the conditions a), b) and c) of Lemma 4.8. This implies that \( M = SU_2 \) admits a CRF fibration over \( SU_2/T^1 \), where \( T^1 \) is the 1-dimensional subgroup generated by the subspace \( \mathfrak{t} = \mathfrak{p} \cap \mathfrak{su}_2 \).

On the other hand, when \( 0 < |t| < 1 \),

\[
N_{\mathfrak{g}}(\mathbb{C}(E_\alpha + tE_{-\alpha})) = \\
= \{ X = a(iH_\alpha) + b(E_\alpha + E_{-\alpha}) + ic(E_\alpha - E_{-\alpha}) \in \mathfrak{su}_2 : [X, E_\alpha + tE_{-\alpha}] \in \mathbb{C}(E_\alpha + tE_{-\alpha}) \} = \{0\}.
\]

Then, by the remarks before Theorem 4.9, the stabilizer \( Q \) of the image of the anti-canonical map \( \phi(SU_2) = SU_2/Q \) is 0-dimensional and the anti-canonical map is a covering map.

(2) We first observe that each non-standard CR structure \( (D_Z, J^{(0)}_t) \) is primitive. In fact, by Lemma 4.8, if one of such CR structures is non-primitive, then there exists a parabolic subalgebra \( \mathfrak{p} \subset \mathfrak{g}_1 \) which verifies a), b) and c) of Lemma 4.8. On the other hand, one can check that in this case, there is no proper subalgebra of \( \mathfrak{g}^C \) which properly contains \( \mathfrak{t}^C + \mathfrak{m}^{10} \), with \( \mathfrak{t}^C = \mathfrak{g}_0' \) and \( \mathfrak{m}^{10} \) as in (5.13).

Now, we want to prove that each non-standard CR structure \( (D_Z, J_t) \) or \( (D_Z, J'_t) \) admits a CRF fibration onto \( G\mathfrak{r}_2(\mathbb{C}^t) = SU_t/S(U_2 \cdot U_{t-2}) \).
Indeed, note that, if we consider the decomposition (5.3) determined by the regular contact element $Z = iH_\mu$, any CR structure $(\mathcal{D}_Z, J_t)$ or $(\mathcal{D}_Z, J'_t)$ corresponding to the holomorphic subspaces defined in (5.11) and (5.12) verifies

$$\mathfrak{l}^C + m^{01} \subset \mathfrak{p} = \mathfrak{g}_0 + \mathfrak{g}_{-1}^{(1)} + \mathfrak{g}_{-2}^{(2)} + \mathfrak{g}_2,$$

$$\mathfrak{l}^C + m'^{10} \subset \mathfrak{p}' = \mathfrak{g}_0 + \mathfrak{g}_{-1}^{(2)} + \mathfrak{g}_{-2}^{(1)} + \mathfrak{g}_2,$$

respectively. A reductive part for both subalgebras $\mathfrak{p}$ and $\mathfrak{p}'$ is $\tau = \tau' = (I + \alpha)^C$. Therefore, by Lemma 4.8, the CR structures $(\mathcal{D}, J_t)$ and $(\mathcal{D}, J'_t)$ are non-primitive and they admit a CR fibration over the Wolf space $SU_{\ell+1}/S(U_2 \cdot U_{\ell-1})$ with typical fiber $S(U_2 \cdot U_{\ell-1})/U_{\ell-1} = SO_3$.

We now want to prove that any non-standard CR structure $(\mathcal{D}_Z, J_t)$ or $(\mathcal{D}_Z, J'_t)$ admits also a CR fibration with standard fiber $S^1$. Let us use the same notation as before and observe that, for any complex holomorphic subspace $m^{10}$ or $m'^{10}$ defined in (5.11) or (5.12), the element $X = E_\mu + tE_{-\mu} \in m^{10} \cap m'^{10}$ is a regular element of $g^C(\mu) \subset g^C$. Hence, if we denote by $\hat{\mathfrak{p}}$ any parabolic subalgebra $\hat{\mathfrak{p}}(\mu) \subset g^C(\mu)$, which properly contains $E_\mu + tE_{-\mu}$ or $E_\mu + t^2E_{-\mu}$, we get that

$$\mathfrak{l}^C + m^{01} \subset \mathfrak{p}_\mu = \mathfrak{g}_0 + \mathfrak{g}_{-1}^{(1)} + \mathfrak{g}_{-2}^{(2)} + \hat{\mathfrak{p}}(\mu),$$

$$\mathfrak{l}^C + m'^{10} \subset \mathfrak{p}'_\mu = \mathfrak{g}_0 + \mathfrak{g}_{-1}^{(2)} + \mathfrak{g}_{-2}^{(1)} + \hat{\mathfrak{p}}(\mu).$$

Note that $\mathfrak{p}_\mu$ and $\mathfrak{p}'_\mu$ are two parabolic subalgebras of $g^C$ which verify a), b) and c) of Lemma 4.8 and hence that the CR structures $(\mathcal{D}, J_t)$ and $(\mathcal{D}, J'_t)$ admit CR fibrations with 1-dimensional fibers.

It remains to check that the anti-canonical map of any non-standard CR structure is a covering map. As in the proof of (1), this reduces to checking that for any holomorphic subspace defined in (5.11) and (5.12), $N_{\mathfrak{g}}(\mathfrak{l}^C + m^{10}) = N_{\mathfrak{g}}(\mathfrak{l}^C + m'^{10}) = \mathfrak{l}^C$ and hence that the image of the anti-canonical map has the same dimension as $G/L$. \Box

6. Classification of non-standard CR structures.

6.1 Notation.

In all this section,

- $(G/L, \mathcal{D}_Z)$ denotes a simply connected non-special homogeneous contact manifold of a compact Lie group $G$;
- $\mathfrak{g} = \mathfrak{g}(Z) = \mathfrak{l} + \mathfrak{R}Z$ is the orthogonal decomposition of the centralizer $\mathfrak{l}$ of $Z$ and $\mathfrak{m}$ is the orthogonal complement to $\mathfrak{l}$ in $\mathfrak{g}$;
- $\mathfrak{h} \subset \mathfrak{g}$ is the orthogonal subalgebra of $\mathfrak{l}$ and hence of $\mathfrak{g}$;
- $\theta = B \circ Z|_\mathfrak{h}$ is the 1-form on $\mathfrak{h}$ dual to $Z$ and $\theta = -i\theta = -iB \circ Z|_\mathfrak{h}$; we will refer to both of them as contact forms;
- $R$ (resp. $R_\alpha$) is the root system of $(\mathfrak{g}^C, \mathfrak{h}^C)$ (resp. of $(\mathfrak{l}^C, \mathfrak{h}^C)$) and $R_\alpha' = R \setminus R_\alpha$;
- $E_\alpha$ is the root vector with root $\alpha$ in the Chevalley normalization (see e.g. [7]);
- a subset $S \subset R$ is called closed subsystem if $(S + S) \cap R \subset S$;
- if $S$ is a closed subsystem of roots, then $\mathfrak{g}(S) \subset \mathfrak{g}^C$ is the subalgebra generated by the root vectors $E_\alpha, \alpha \in S$;
- recall that the root vectors $E_\alpha, \alpha \in R'$, span $\mathfrak{m}^C$;
- $\mathfrak{m}(\alpha)$ denotes the irreducible $\mathfrak{f}^C$-submodules of $\mathfrak{m}^C$, with highest weight $\alpha \in R'$;
- if $\mathfrak{m}(\alpha)$ and $\mathfrak{m}(\beta)$ are equivalent as $\mathfrak{f}^C$-modules, we denote by $\mathfrak{m}(\alpha) + t \mathfrak{m}(\beta)$ the irreducible $\mathfrak{f}^C$-module with the highest weight vector $E_\alpha + t E_\beta, \alpha, \beta \in R'$, $t \in \mathbb{C}$; note that together with $\mathfrak{m}(\beta)$, these moduli exhaust all the irreducible $\mathfrak{f}^C$-submodules of $\mathfrak{m}(\alpha) + \mathfrak{m}(\beta)$ (see Lemma 6.1);
- by Dynkin graph $\Gamma$ we will understand the Dynkin graph associated with a root system $R$ of a compact semisimple Lie algebra $\mathfrak{g}$; we associate with the nodes of $\Gamma$ the simple roots of $R$ as in [7] (see Table 4 in the Appendix).

6.2 Preliminaries.

By the results in §5, the classification of invariant CR structures reduces to the classification of non-standard CR structures on homogeneous contact manifolds of non-special type. This will be the contents of §6.3 and §6.4.

In this section we give two important lemmata that settle the main tools for the classification. The first Lemma is an immediate corollary of Proposition 3.9.

**Lemma 6.1.** Let $(M = G/L, \mathcal{D}_Z, J)$ be a homogeneous CR manifold associated with holomorphic subspace $\mathfrak{m}^{10} \subset \mathfrak{m}^C$ and $J$ the associated complex structure on $\mathfrak{m}$. Assume also that $G \neq G_2$ or that $G = G_2$ and that the contact form $\vartheta$ is not proportional to a short root of $R$.

Then a minimal $J$-invariant $\mathfrak{f}^C$-submodule $\mathfrak{n}$ of $\mathfrak{m}^C$ is either $\mathfrak{f}^C$-irreducible (and hence $\mathfrak{n} = \mathfrak{m}(\alpha)$ for some $\alpha \in R'$) or it is the sum $\mathfrak{m}(\alpha) + \mathfrak{m}(\beta)$ of two such $\mathfrak{f}^C$-modules, where the roots $\alpha$ and $\beta$ are $\vartheta$-congruent (i.e. $\beta = \alpha + \lambda \vartheta$, for some $\lambda \in \mathbb{R}$).

**Proof.** Consider the decomposition $\mathfrak{m}^C = \sum \mathfrak{m}(\gamma)$ into irreducible $\mathfrak{f}$-submodules as in §3.3. The claim follows immediately from the fact that any $\text{ad}_I$-invariant complex structure $J$ on $\mathfrak{m}$ preserves the $\mathfrak{f}^C$-isotypic components (i.e. the sum of all mutually equivalent irreducible $\mathfrak{f}^C$-modules) and that, under the hypotheses of Proposition 3.9, the multiplicity of any irreducible $I$-module $\mathfrak{m}(\gamma)$ is less or equal to 2. □

**Lemma 6.2.** Let $(G/L, \mathcal{D}_Z, J)$ be a homogeneous CR manifold with non-standard CR structure. Then $G$ is either simple or of the form $G = G_1 \times G_2$, where each $G_i$ is simple.

Moreover, if $G = G_1 \times G_2$ and $R = R_1 \cup R_2$ is the corresponding decomposition of the root system, then there exist two roots $\mu_1 \in R_1, \mu_2 \in R_2$, such that the pairs of roots $(\mu_1, -\mu_2)$ and $(-\mu_1, \mu_2)$ are the only ones which are $\vartheta$-congruent; in particular, $\vartheta = \mu_1 + \mu_2$ is proportional to no root.

**Proof.** Since the CR structure $(\mathcal{D}_Z, J)$ is non-standard, the associated complex structure $J$ on $\mathfrak{m}$ is not $\text{ad}_I$-invariant; in particular there exists some minimal $J$-invariant $\mathfrak{f}^C$-module in $\mathfrak{m}^C$, which is not $\mathfrak{f}^C$-irreducible. By Lemma 6.1, there exist at least two roots $\alpha, \beta$, which are $\vartheta$-congruent. Without loss of generality, we may assume that $\vartheta = \alpha - \beta$. 

- a subset $S \subset R$ is called closed subsystem if $(S + S) \cap R \subset S$;
- if $S$ is a closed subsystem of roots, then $\mathfrak{g}(S) \subset \mathfrak{g}^C$ is the subalgebra generated by the root vectors $E_\alpha, \alpha \in S$;
If \( \vartheta \) is proportional to some root \( \gamma \), then this root belongs to some summand \( g_i \) of \( g \), \( i = 1, \ldots, r \). Hence, \( \mathfrak{t} = C_{g}(Z) \) contains all other simple summands of \( g \) and the same holds for \( I \). By effectivity, this implies that \( g = g_1 \).

If \( \vartheta = \alpha - \beta \) is not proportional to any root and \( \alpha \) and \( \beta \) belong to the same summand \( g_1 \), then \( g = g_1 \) as before. Assume that they belong to two different summands \( g_1 \) and \( g_2 \). The same arguments of before show that \( g = g_1 \oplus g_2 \) and that \( \pm(\alpha, \beta) \) are the only pairs of roots which are \( \vartheta \)-congruent. □

We will perform the classification by considering separately two cases: when the contact form \( \vartheta \) is proportional to a root and when it is not proportional to any root. Note that by Lemma 6.2, the first case may occur only when \( G \) is simple.

6.3 Case when the contact form is proportional to a root.

Recall that the Weyl group of a simple Lie group acts transitively on the set of roots of the same length. In particular any long root can be considered as a maximal root. Since we assume that the contact manifold \( (M = G/L, D_Z) \) is non-special and \( G \) is simple, we may suppose that \( \vartheta \) is proportional to a short root (i.e. strictly shorter than a long root) and hence \( G \) equals either \( SO_{2n+1}, Sp_n \) or \( F_4 \). Note that if \( G = G_2 \) then any contact manifold \( (G_2/L, D_Z) \), with contact form \( \vartheta \) proportional to a short root, is special (see §3.2.2).

**Proposition 6.3.** Let \( (G/L, D_Z) \) be a homogeneous non-special contact manifold of a simple group \( G \), such that the contact form \( \vartheta \) is proportional to a root. Then:

1. \( G/L \) is \( SO_{2n+1}/SO_{2n-1}, Sp_n/Sp_1 \times Sp_{n-2} \) or \( F_4/Sp_7 \) and \( \vartheta \) is proportional to a short root of \( G \);
2. there exists a 1-1 correspondence between the invariant CR structures on \( (G/L, D_Z) \) (determined up to a sign) and the points of the unit disc \( D \subset \mathbb{C} \);
3. more precisely, any point \( t \in D \) corresponds to the CR structure \((D_Z, J_t)\) whose holomorphic subspace \( m^{10} \) is listed in the following table (see §6.1 for notation):

| \( G/L \) | \( \vartheta \) | \( m^{10} \) |
|----------|---------|---------|
| \( SO_{2n+1}/SO_{2n-1} \) | \( \mathbb{S}(S^{2n}) \) | \( \varepsilon_1 \) | \( m(\varepsilon_1 + \varepsilon_2) + tm(\varepsilon_1 + \varepsilon_2) \) |
| \( Sp_n/Sp_1 \times Sp_{n-2} \) | \( \mathbb{S}(\mathbb{H}P^{n-1}) \) | \( \varepsilon_1 + \varepsilon_2 \) | \( (m(2\varepsilon_1) + t^2 m(-2\varepsilon_2)) \oplus (m(\varepsilon_1 + \varepsilon_3) + tm(-\varepsilon_2 + \varepsilon_3)) \) |
| \( F_4/Sp_{7} \) | \( \mathbb{S}(\mathbb{O}P^2) \) | \( \varepsilon_1 \) | \( (m(\varepsilon_1 + \varepsilon_2) + t^2 m(-\varepsilon_1 + \varepsilon_2)) \oplus (m(1/2(\varepsilon_1 + \varepsilon_2 + \varepsilon_3 + \varepsilon_4)) + tm(1/2(\varepsilon_1 + \varepsilon_2 + \varepsilon_3 + \varepsilon_4))) \) |

4. a CR structure \((D_Z, J_t)\) is standard if and only if \( t = 0 \); in all other cases it is primitive.

**Proof.** For each group \( G \) equal to \( SO_{2\ell+1}, Sp_\ell \) or \( F_4 \) we may assume that \( \vartheta \) is the short root \( \vartheta = \varepsilon_1, \varepsilon_1 + \varepsilon_2 \) or \( \varepsilon_1 \), respectively. The associated decomposition \( g = I + \mathbb{R}Z + m \) is given in Table 2 of the Appendix. It is not difficult to determine the decomposition of \( m^C \) into irreducible submoduli. The result is given in Table 2. Then one has to find all decompositions \( m^C = m^{10} + m^{01} \) into two \( f^C \)-modules.
which satisfy the following conditions: a) \( m^{01} = \overline{m^{10}} \); b) \([m^{10}, m^{10}] \subset m^{10} + \mathfrak{C} \). The moduli \( m^{10} \) which satisfy condition a) are of the following form:

\[
G = SO_{2t+1} : \quad m^{10} = m^{10}_t = m(\varepsilon_1 + \varepsilon_2) + t m(-\varepsilon_1 + \varepsilon_2);
\]

\[
G = Sp_t : \quad m^{10} = m^{10}_{t,s} = (m(2\varepsilon_1) + sm(-2\varepsilon_2)) \oplus (m(\varepsilon_1 + \varepsilon_3) + t m(-\varepsilon_2 + \varepsilon_3));
\]

\[
G = F_4 : \quad m^{10} = m^{10}_{t,s}' = (m(\varepsilon_1 + \varepsilon_2) + sm(-\varepsilon_1 + \varepsilon_2)) \oplus (m(1/2(\varepsilon_1 + \varepsilon_2 + \varepsilon_3 + \varepsilon_4)) + t m(1/2(-\varepsilon_1 + \varepsilon_2 + \varepsilon_3 + \varepsilon_4))
\]

for some \( s, t \neq 0 \). One can easily check that \( m^{10}_{t,s} \) verifies condition b) for every \( t \). The module \( m^{10}_{t,s} \) verifies condition b) if and only if \( s = t^2 \). To prove it one should observe that the only brackets between \( \mathfrak{C} \)-weight vectors in \([m^{10}_{t,s}, m^{10}_{t,s}]\), which are non-trivial modulo \( \mathfrak{C} \), are

\[
[E_{\varepsilon_1+\varepsilon_2}, t E_{-\varepsilon_2+\varepsilon_1}, E_{\varepsilon_1-\varepsilon_2} + t E_{-\varepsilon_2-\varepsilon_1}] \equiv
\]

\[
N_{\varepsilon_1+\varepsilon_2, \varepsilon_1-\varepsilon_2} E_{\varepsilon_1} + t^2 N_{-\varepsilon_2+\varepsilon_1, \varepsilon_2+\varepsilon_1} E_{-\varepsilon_2-\varepsilon_1} \pmod{\mathfrak{C}}
\]

\[
N_{\varepsilon_1+\varepsilon_2, \varepsilon_1-\varepsilon_2} E_{\varepsilon_1} + t^2 N_{-\varepsilon_2+\varepsilon_1, \varepsilon_2+\varepsilon_1} E_{-\varepsilon_2-\varepsilon_1} \pmod{\mathfrak{C}}
\]

By a straightforward computation, it follows that these vectors are in \( m^{10}_{t,s} \) if and only if \( s = t^2 \).

A similar argument shows that also \( m^{10}_{t,s}' \) verifies condition b) if and only if \( s = t^2 \).

Observe that up to an exchange between \( m^{10} \) and \( m^{01} \) (which corresponds to changing the sign of complex structure \( J \)), we may always assume that \( |t| \leq 1 \). It remains to check the condition \( m^{01} \cap m^{10} = \{0\} \): in all cases, this implies \( \det \begin{pmatrix} 1 & t \\ t & 1 \end{pmatrix} \neq 0 \) and hence that \( |t| < 1 \).

To prove (4), note that, in all cases listed in the table above, \( N \cap (\mathfrak{C} + m^{01}) \) contains \( \mathbb{Z} \) only if \( t = 0 \) and hence, by Theorems 4.9 and 4.11, this is the only case when the CR structure is standard. Moreover, in all cases, if \( t \neq 0 \) there exists no proper parabolic subalgebra \( \mathfrak{p} \supset \mathfrak{C} \) which verifies the conditions of Lemma 4.8. \( \square \)

6.3 Case when the contact form is not proportional to any root.

In this case we obtain the following classification.

**Proposition 6.4.** Let \( (M = G/L, \mathcal{D}_Z) \) be a contact manifold with contact form \( \vartheta \) not proportional to any root. If it admits a primitive invariant CR structure \((\mathcal{D}_Z, J)\), then it is one of the following.

If \( G \) is simple then

a) \( G/L = SO_{2n}/SO_{2n-2}, n > 2 \), and \( \vartheta \) is either \( \varepsilon_1 \) or, when \( n = 4, \varepsilon_1 + \varepsilon_2 + \varepsilon_3 \pm \varepsilon_4 \); moreover the holomorphic subspace of the CR structure \((\mathcal{D}_Z, J)\) is given by

\[
m^{10} = m(\varepsilon_1 + \varepsilon_2) + t m(\beta)
\]

where \( \beta = -\varepsilon_1 + \varepsilon_2, -\varepsilon_3 - \varepsilon_4 \) or \(-\varepsilon_3 + \varepsilon_4 \) (the last two cases occur only for \( n = 4 \)) and \( t \) belongs to the punctured unit disc \( D \setminus \{0\} \subset \mathbb{C} \);
b) $G/L = Spin_7/SU_3 = S(S^7) = S^7 \times S^6$, $\vartheta = \varepsilon_1 + \varepsilon_2 + \varepsilon_3$ and the holomorphic subspace of $(D_Z, J)$ is given by

$$m^{10} = m(\varepsilon_1 + \varepsilon_2) + tm(-\varepsilon_3) + \overline{m(\varepsilon_1 + \varepsilon_2)} + \frac{1}{t} \overline{m(-\varepsilon_3)} \quad (6.2)$$

for some $t \in D \setminus \{0\}$.

If $G$ is not simple then

c) $G/L = SU_2 \times SU_2/T^1 = S(S^3) = S^3 \times S^2$, $\vartheta = (\varepsilon_1 - \varepsilon_2) - (\varepsilon'_1 - \varepsilon'_2)$ and the holomorphic subspace of $(D_Z, J)$ is

$$m^{10} = C(E_{\varepsilon_1 - \varepsilon_2} + tE_{\varepsilon'_1 - \varepsilon'_2}) + C(E_{-(\varepsilon_1 - \varepsilon_2)} + \frac{1}{t} E_{-(\varepsilon'_1 - \varepsilon'_2)}) \quad (6.3)$$

In all cases we considered $\vartheta$ up to a factor and up to a transformation from the Weyl group $W(R)$, and $J$ up to a sign.

**Proposition 6.5.** A homogeneous contact manifold $(G/L, D_Z)$ with contact form $\vartheta$ not proportional to any root, admits a non-standard non-primitive CR structure if and only if it is $G$-contact diffeomorphic to the contact manifold $(M(\Gamma) = G/L, D_{Z(\Gamma)})$ associated with a non-special CR-graph $(\Gamma, \vartheta(\Gamma))$ (see Definition 1.7).

For any invariant CR structure $(D_{Z(\Gamma)}, J)$ on $M(\Gamma) = G/L$ the natural projection $\pi : M(\Gamma) = G/L \to F_2(\Gamma) = G/Q$ is holomorphic w.r.t. the complex structure $J_2(\Gamma)$ or $-J_2(\Gamma)$.

The CR structures for which $\pi$ is holomorphic w.r.t. $J_2(\Gamma)$ are in 1-1 correspondence with the invariant CR structures on the fiber $C = Q/L$ subordinated to the induced contact structure $D_{Z(\Gamma)} \cap TC$.

More precisely, if

$$q^C = t^C + CZ + m^C_0 + m_0^{01}, \quad g^C = q^C + m_1^{10} + m_{12}^{01}$$

are the two decompositions of $q^C$ and $g^C$ associated with an invariant CR structure on the fiber $C = Q/L$ and with the complex structure $J_2(\Gamma)$ on $F_2(\Gamma)$, then

$$m^{10} = m_1^{10} + m_{12}^{10} \quad (6.4)$$

is the holomorphic subspace of the corresponding CR structure on $M(\Gamma)$. Moreover, this CR structure is non-standard if and only if the CR structure on $C$ is primitive.

The rest part of the paper is devoted to the proof of Propositions 6.4 and 6.5. We need some additional notations.

For a fixed CR structure $(D_Z, J)$, we set

$$R_j^{\pm} = \{ \alpha \in R' : J(E_\alpha) = \pm i E_\alpha \}, \quad R_j = R_j^+ \cup R_j^- \quad (6.5)$$

and we define the subspaces

$$m_j^+ = \sum_{\beta \in R_j^+} CE_\beta, \quad m_j = m_j^+ + m_j^-, \quad c = \sum_{\beta \in R_\omega} CE_\beta \subset m^C \quad (6.6)$$

Note that $J$ is standard if and only if $R_j = R'$. We define also the closed subsystem

$$R_\epsilon = [R_\epsilon] = R \cap \operatorname{span}_R(R_\epsilon), \quad \tilde{R}_\epsilon = R_\omega \cap \tilde{R}_\epsilon, \quad \tilde{R}_\epsilon = R_\omega \cap \tilde{R}_\epsilon,$$

and we set $R'_\omega = R_\omega \setminus \tilde{R}_\epsilon$.

The following Lemma collects some basic properties of these objects.
Lemma 6.6.

1. $R_J = -R_J$ and $R_e = -R_e$;
2. for any $\alpha \in R_e$ there exists exactly one root $\beta \in R_e$ which is $\vartheta$-congruent to $\alpha$;
3. for any pair $\alpha, \beta \in R_e$ of $\vartheta$-congruent roots, there exist two uniquely determined complex numbers $\lambda, \mu \neq 0$ such that
\[ e_{\alpha, \beta} = E_\alpha + \lambda E_\beta \in m^{10}, \quad f_{\alpha, \beta} = E_\alpha + \mu E_\beta \in m^{01}. \] (6.7)
4. $(R_J^\pm + R_o) \cap R \subset R_J^\pm$ and $(R_e + R_o) \cap R \subset R_e$;
5. $(R_J^\pm + R_e) \cap R \subset R_J^\pm \cup R_e \cup R_o$.

Proof. (1) is clear. To see (2), (3) and (4), observe that $\alpha \in R_J$ if and only if $E_\alpha$ belongs to an irreducible $\mathfrak{f}^\vartheta$-module which is also $J$-invariant; hence (2), (3) and (4) follow from Lemma 6.1 and Corollary 3.10.

The proof of (5) is the following. Let $\gamma \in R_J^\pm$ and $\alpha, \beta \in R_e$ a pair of two $\vartheta$-congruent roots. If $\gamma + \alpha \in R_J$, consider the element $f_{-\alpha, -\beta} \in m^{01}$ as defined in (6.7). Since $E_{\gamma + \alpha} \in m^{01}$, by the integrability condition
\[ [E_{\gamma + \alpha}, f_{-\alpha, -\beta}] = CE_\gamma + X \in m^{01} + \mathfrak{l}^C \]
for some $C \neq 0$ and $X \notin CE_\gamma$. This implies that $\gamma \in R_J^-$: contradiction. □

For any $\alpha \in R$, a root $\beta \in R$, which is $\vartheta$-congruent to $\alpha$, is said to be $\vartheta$-dual to $\alpha$ and we say that $(\alpha, \beta)$ is a $\vartheta$-dual pair. By Corollary 3.10 any root admits at most one $\vartheta$-dual root; by Lemma 6.6 (3), any root in $R_e$ has exactly one $\vartheta$-dual root.

Lemma 6.7. Let $(\alpha, \alpha')$ be a $\vartheta$-dual pair in $R_e$. Then the root subsystem $\tilde{R} = R \cap \text{span}_{\mathbb{Z}} \{\alpha, \alpha'\}$ is of type $A_1 + A_1$. In particular $\alpha \perp \alpha'$ and $\alpha \pm \alpha' \notin R$.

Proof. Assume that $\tilde{R} \neq A_1 + A_1$. Then $\tilde{R}$ is a root system of type $A_2, B_2$ or $G_2$. Since by assumptions $\vartheta = \alpha - \alpha'$ is proportional to no root, looking at the corresponding root systems, we find that up to a transformation from the Weyl group there are the following possibilities:
\begin{align*}
R &= A_2 : \quad \alpha = \xi_0 - \xi_2, \quad \alpha' = \xi_2 - \xi_1; \\
\tilde{R} &= B_2 : \quad \alpha = \xi_1, \quad \alpha' = -\xi_1 + \xi_2; \\
\tilde{R} &= G_2 : \quad \alpha = -\xi_2, \quad \alpha' = -\xi_1 + \xi_2. \\
\end{align*}

Note that in each of these three cases, $\alpha + \alpha' = \beta \in R$.

Case $\tilde{R} = A_2$.

In this case $\vartheta = (\xi_0 - \xi_2) - (\xi_2 - \xi_1) = \xi_0 + \xi_1 - 2\xi_2$ and $\beta = \alpha + \alpha'$ is orthogonal to $\vartheta$ and hence it belongs to $R_o$. Moreover $\mathfrak{l}^C = C_{\vartheta'}(Z)$ contains the subalgebra
\[ \mathfrak{l}' = CH_{\xi_0 - \xi_1} + CE_{\xi_0 - \xi_1} + CE_{\xi_1 - \xi_0}. \]

At the same time, by Lemma 6.6 (3), $m^{01}$ contains the element $f_{\xi_0 - \xi_2, \xi_2 - \xi_1} = E_{\xi_0 - \xi_2} + \mu E_{\xi_2 - \xi_1}$, with some fixed $\mu \neq 0$. Since $m^{01}$ is $\mathfrak{l}^C$-invariant, $m^{01}$ contains also the subspace
\[ [E_{\xi_1 - \xi_0}, f_{\xi_0 - \xi_2, \xi_2 - \xi_1}] = C(E_{\xi_1 - \xi_2} - \mu E_{\xi_2 - \xi_0}). \]
By integrability condition, this implies that
\[ [E_{ε_0−ε_2} + μE_{ε_2−ε_1}, E_{ε_1−ε_2} − μE_{ε_2−ε_0}] = μ(−H_{ε_0−ε_2} + H_{ε_2−ε_1}) \in m^{01} + l^C \]
and hence we conclude that \( −H_{ε_0−ε_2} + H_{ε_2−ε_1} \in l^C \). But this cannot be because \( −H_{ε_0−ε_2} + H_{ε_2−ε_1} \) is not orthogonal to \( Z = iB^{−1} ∩ \vartheta \).

Case \( \tilde{R} = B_2 \) or \( G_2 \).

Then \( β = α + α' \) is not orthogonal to \( ϑ = α − α' \) and, moreover,
\[(β + ℜϑ) \cap R = \emptyset.
\]
These two facts show that \( β \in R \setminus (R_ε ∪ R_o) = R_J \). Changing the sign of \( α \) and \( α' \), if necessary, we may assume that \( β \in R^+_J \).

Consider the vector \( f_{α, α'} = E_{α} + μE_{α'} \in m^{01} \) which is defined by (6.7). Then \( E_{α} + μE_{α'} = E_{−α} + \tilde{μ}E_{−α'} \in m^{10} \) and by integrability condition its commutator with \( E_β \) is also in \( m^{10} + l^C \). Therefore
\[ [E_{−α} + \tilde{μ}E_{−α'}, E_β] = N_{−α, β}E_{α'} + \tilde{μ}N_{−α', β}E_α \in m^{10}. \]

Hence the coefficient \( λ \) of the vector \( e_{α, α'} \) defined by (6.7) is
\[ λ = \frac{N_{−α, β}}{\tilde{μ}N_{−α', β}}. \quad (6.8) \]
Since we use the Chevalley normalization (see §6.1), \( N_{−α, β} = ±(p + 1) \) for any two roots \( α, β \), where \( p \geq 0 \) is the maximal integer such that \( β + pα \in \tilde{R} \) (see e.g. [7]). Using this formula, we obtain from (6.8) that if \( \tilde{R} = B_2 \), \( λ\tilde{μ} = ±2 \), while if \( \tilde{R} = G_2 \), \( λ\tilde{μ} = ±3 \).

On the other hand, by integrability condition
\[ [e_{α, α'}, f_{α, α'}] = [E_{α} + λE_{α'}, E_{−α} + \tilde{μ}E_{−α'}] = H_α + λ\tilde{μ}H_{α'} \in l^C. \]
This means that \( ϑ(H_α + λ\tilde{μ}H_{α'}) = 0 \), i.e. that
\[ < ϑ|α > + λ\tilde{μ} < ϑ|α' >= 0, \]
where \( < ϑ|α >= 2(ϑ, α)/(α, α) \). Hence for \( ϑ = α − α' \), we obtain
\[ 2 − < α'|α > + λ\tilde{μ}−2 + < α|α' > = 0. \]
In case \( \tilde{R} = B_2 \), \( < α'|α >= −2 \) and \( < α|α' >= −1 \) so that \( λ\tilde{μ} = 4/3 \); in case \( \tilde{R} = G_2 \), \( < α'|α >= −3 \) and \( < α|α' >= −1 \) so that \( λ\tilde{μ} = 5/3 \). In both cases we get a contradiction with the previously determined values for \( λ\tilde{μ} \). \( □ \)

Now we determine the possible types of the root subsystem \( \tilde{R}_ε = R ∩ span_R(R_ε) \).
Lemma 6.8. If $\tilde{R}_e$ is not of the form $A_1 \cup A_1$, then $\tilde{R}_e$ and $R$ are both indecomposable root systems.

Proof. By Lemma 6.7, we may assume that rank $\tilde{R}_e > 2$. Suppose that $\tilde{R}_e$ is decomposable into two mutually orthogonal subsystems $R_1$ and $R_2$. Let $\alpha \in R_1 \cap R_e$, $\alpha' \in R_2 \cap R_e$ and $\beta, \beta'$ the $\vartheta$-dual roots of $\alpha$ and $\alpha'$, respectively. Since $\vartheta$ cannot be in the span of $R_1$, it is clear that $\beta \in R_2$ and that $\beta' \in R_1$. Then the identity

$$\mathbb{R} \vartheta = \mathbb{R}(\alpha - \beta) = \mathbb{R}(\alpha' - \beta')$$

implies that $\alpha + \rho \beta' = \rho \alpha' + \beta = 0$ for some $\rho \neq 0$. From this follows that $\beta' = -\alpha$, $\beta = -\alpha'$ and that rank$\tilde{R}_e = 2$: contradiction.

A similar contradiction arises if we replace $\tilde{R}_e$ by $R$. □

Note that by Lemma 6.8, if $G = G_1 \times G_2$, then the only possibility for $\tilde{R}_e$ is $A_1 \cup A_1$.

The following Lemma gives a more detailed description of the root subsystem $\tilde{R}_e$.

Lemma 6.9. The root subsystem $\tilde{R}_e$ has type $D_\ell$, $\ell > 1$ or $B_3$ and, up to a factor and a transformation from the Weyl group $W = W(R)$, the contact form $\vartheta$ is one of the following:

1. if $\tilde{R}_e = D_2 = A_1 + A_1$ and $\alpha, \alpha'$ are roots of the summands $A_1$ and $A_1$, then $\vartheta = \alpha - \alpha'$;
2. if $\tilde{R}_e = D_3$ or $D_\ell$, with $\ell > 4$, then $\vartheta = 2 \varepsilon_1$;
3. if $\tilde{R}_e = D_4$ then $\vartheta = 2 \varepsilon_1$ or $\vartheta = \varepsilon_1 + \varepsilon_2 + \varepsilon_3 + \varepsilon_4$ or $\vartheta = \varepsilon_1 + \varepsilon_2 + \varepsilon_3 - \varepsilon_4$;
4. if $\tilde{R}_e = B_3$ then $\vartheta = \varepsilon_1 + \varepsilon_2 + \varepsilon_3$.

Note that in case $\tilde{R}_e = D_4$, all three contact forms $\vartheta$ in (3) are equivalent with respect to automorphisms of the root system.

Proof. From Lemma 6.8, it is sufficient to consider the case when rank $\tilde{R}_e > 2$ and $\tilde{R}_e$ is indecomposable. For each indecomposable root system $\tilde{R}_e$ we describe, up to a transformation from the Weyl group, all pairs of roots $(\alpha, \alpha')$, which are orthogonal and such that $\alpha \pm \alpha' \notin R$. By Lemma 6.7 such pairs are the only candidates for $\vartheta$-dual pairs in $R_e$. For each case, we consider the corresponding form $\vartheta = \alpha - \alpha'$, and describe all $\vartheta$-dual pairs in $\tilde{R}_e$. Then, assuming that $\alpha, \alpha' \in R_e$, we check if the case is possible looking if the $\vartheta$-dual pairs in $R_e$ may generate $\tilde{R}_e$.

Case (A): $\tilde{R}_e = A_\ell$.

Up to a transformation from the Weyl group, the pair $(\alpha, \alpha')$ is equal to $$(\varepsilon_1 - \varepsilon_2, \varepsilon_3 - \varepsilon_4).$$ Then $\vartheta = (\varepsilon_1 - \varepsilon_2) - (\varepsilon_3 - \varepsilon_4)$ and the $\vartheta$-dual pairs are (up to sign)

$$(\varepsilon_1 - \varepsilon_2, \varepsilon_3 - \varepsilon_4); \quad (\varepsilon_1 - \varepsilon_3, \varepsilon_2 - \varepsilon_4).$$

Since $\beta = \varepsilon_2 - \varepsilon_3 \in R_\alpha = (\vartheta)^1 \cap R$, then $\varepsilon_1 - \varepsilon_3 = \alpha + \beta \in R_e$ and hence also the second $\vartheta$-dual pair is in $R_e$. In particular rank$\tilde{R}_e = 3$ and $\tilde{R}_e = A_3 = D_3$.

Case (B): $\tilde{R}_e = B_\ell$.

We have three possibilities for $(\alpha, \alpha')$ according to their lengths:

1. $(\alpha, \alpha') = (\varepsilon_1 + \varepsilon_2, - (\varepsilon_3 + \varepsilon_4));$
2. $(\alpha, \alpha') = (\varepsilon_1 + \varepsilon_2, - \varepsilon_3);$
3. $(\alpha, \alpha') = (\varepsilon_1, \varepsilon_2).$
The last case is not possible, since we assume that \( \vartheta = \alpha - \alpha' \) is proportional to no root.

i) \( \vartheta = \varepsilon_1 + \varepsilon_2 + \varepsilon_3 + \varepsilon_4 \) and the \( \vartheta \)-dual pairs are (up to sign)

\[
(\varepsilon_1 + \varepsilon_2, -(\varepsilon_3 + \varepsilon_4)) ; \quad (\varepsilon_1 + \varepsilon_3, -(\varepsilon_2 + \varepsilon_4)) ; \quad (\varepsilon_1 + \varepsilon_4, -(\varepsilon_2 + \varepsilon_3)).
\] (6.9)

As in case (A), one can check that all these \( \vartheta \)-dual pairs are in \( R_\varepsilon \) and that they span a space of dimension 4. Since the \( \vartheta \)-dual pairs consist of long roots, they cannot generate the root system \( B_\varepsilon \) and hence this case is impossible.

ii) \( \vartheta = \varepsilon_1 + \varepsilon_2 + \varepsilon_3 \) and the \( \vartheta \)-dual pairs are (up to sign)

\[
(\alpha = \varepsilon_1 + \varepsilon_2, \alpha' = -\varepsilon_3) ; \quad (\beta = \varepsilon_2 + \varepsilon_3, \beta' = -\varepsilon_1) ; \quad (\gamma = \varepsilon_3 + \varepsilon_1, \gamma' = -\varepsilon_2).
\] (6.10)

Again all pairs in (6.10) consist of roots in \( R_\varepsilon \). This implies that rank \( \tilde{R}_\varepsilon = 3 \).

**Case (C):** \( \tilde{R}_\varepsilon = C_\varepsilon \).

As in case (B), we have three possibilities.

i) \( (\alpha, \alpha') = (\varepsilon_1 + \varepsilon_2, -(\varepsilon_3 + \varepsilon_4)) \);
ii) \( (\alpha, \alpha') = (\varepsilon_1 + \varepsilon_2, -2\varepsilon_3) \);
iii) \( (\alpha, \alpha') = (2\varepsilon_1, -2\varepsilon_2) \).

As in (B), the last case is not possible.

i) \( \vartheta = \varepsilon_1 + \varepsilon_2 + \varepsilon_3 + \varepsilon_4 \) and the \( \vartheta \)-dual pairs are (up to sign) in (6.9). This implies that \( \pm 2\varepsilon_i \in R_J \), \( i = 1, \ldots, 4 \), because it has no \( \vartheta \)-dual root and it is not orthogonal to \( \vartheta \). Note also that the roots \( \varepsilon_i - \varepsilon_j \), \( i, j = 1, \ldots, 4 \), belong to \( R_\varepsilon \), because they are orthogonal to \( \vartheta \). Therefore

\[
R_\varepsilon \subset \{ \pm(\varepsilon_i + \varepsilon_j), \quad 1 \leq i, j \leq 4 \} \subset (R_\alpha + \{ \pm 2\varepsilon_i \}) \cap R \subset R_J
\]

and this is a contradiction.

ii) \( \vartheta = \varepsilon_1 + \varepsilon_2 + 2\varepsilon_3 \).

In this case, up to sign, there is only one \( \vartheta \)-dual pair, that is \( (\varepsilon_1 + \varepsilon_2, -2\varepsilon_3) \). On the other hand, \( \varepsilon_1 - \varepsilon_2 \in R_\alpha \) and hence \( 2\varepsilon_1 = (\varepsilon_1 + \varepsilon_2) + (\varepsilon_1 - \varepsilon_2) \in R_\varepsilon \); contradiction.

**Case (D):** \( \tilde{R}_\varepsilon = D_\varepsilon \).

Since \( D_3 = A_3 \), we may assume that \( \ell \geq 4 \). Then we have three possibilities:

i) \( (\alpha, \alpha') = (\varepsilon_1 + \varepsilon_2, -(\varepsilon_3 + \varepsilon_4)) \);
ii) \( (\alpha, \alpha') = (\varepsilon_1 + \varepsilon_2, -(\varepsilon_3 - \varepsilon_4)) \);
iii) \( (\alpha, \alpha') = (\varepsilon_1 + \varepsilon_2, -(\varepsilon_1 - \varepsilon_2)) \).

i) \( \vartheta = \varepsilon_1 + \varepsilon_2 + \varepsilon_3 + \varepsilon_4 \) and the \( \vartheta \)-dual pairs are given (up to sign) in (6.9) and they all belong to \( R_\varepsilon \). Hence the rank of \( \tilde{R}_\varepsilon \) is 4.

A similar argument shows that rank \( \tilde{R}_\varepsilon = 4 \) in case ii), where \( \vartheta = \varepsilon_1 + \varepsilon_2 + \varepsilon_3 - \varepsilon_4 \).

iii) \( \vartheta = 2\varepsilon_1 \) and the \( \vartheta \)-dual pairs are \( (\varepsilon_1 + \varepsilon_i, \varepsilon_1 - \varepsilon_i) \), with \( i = 2, \ldots, \ell \), they are all in \( R_\varepsilon \) and they span the whole system \( D_\varepsilon \).

**Case (E):** \( \tilde{R}_\varepsilon = E_6, E_7 \) or \( E_8 \).
Let $\alpha, \alpha' \in R_\ell$ be a $\vartheta$-dual pair. Since $\alpha$ and $\alpha'$ are orthogonal, we may included them into a subsystem II of simple roots. According to the type of $\tilde{R}_\ell$, without loss of generality, we may assume that $\alpha'$ is one of the following:

\[ \tilde{R}_\ell = E_6 : \quad \alpha' = \varepsilon_4 + \varepsilon_5 + \varepsilon_6 + \varepsilon ; \]
\[ \tilde{R}_\ell = E_7 : \quad \alpha' = \varepsilon_5 + \varepsilon_6 + \varepsilon_7 + \varepsilon_8 ; \]
\[ \tilde{R}_\ell = E_8 : \quad \alpha' = \varepsilon_6 + \varepsilon_7 + \varepsilon_8 . \]

For each case, it follows that $\alpha = \varepsilon_i - \varepsilon_{i+1}$ for some $i \neq \ell - 3$ where $\ell = \text{rank} \tilde{R}_\ell$. It can be easily checked that, using permutations of the vectors $\varepsilon_i$ which belong to the Weyl group of $E_\ell$ and which preserve $\alpha'$, we may assume that either $\alpha = \varepsilon_1 - \varepsilon_2$ or $\alpha = \varepsilon_{\ell-1} - \varepsilon_\ell = -\sum_{i=1}^{\ell-2} \varepsilon_i - 2\varepsilon_\ell$. Therefore we have the following possibilities:

If $\tilde{R}_\ell = E_6$:

i) $\alpha = \varepsilon_1 - \varepsilon_2$ and $\vartheta = \alpha' - \alpha = -\varepsilon_1 + \varepsilon_2 + \varepsilon_4 + \varepsilon_5 + \varepsilon_6 + \varepsilon$;

ii) $\alpha = \varepsilon_5 - \varepsilon_6$ and $\vartheta = \varepsilon_4 + 2\varepsilon_6 + \varepsilon = \varepsilon_6 - \varepsilon_1 - \varepsilon_2 - \varepsilon_3 - \varepsilon_5 + \varepsilon$;

If $\tilde{R}_\ell = E_7$:

iii) $\alpha = \varepsilon_1 - \varepsilon_2$ and $\vartheta = -\varepsilon_1 + \varepsilon_2 + \varepsilon_5 + \varepsilon_6 + \varepsilon_7 + \varepsilon_8$;

iv) $\alpha = \varepsilon_6 - \varepsilon_7$ and $\vartheta = \varepsilon_5 + 2\varepsilon_7 + \varepsilon_8 = \varepsilon_7 - \varepsilon_1 - \varepsilon_2 - \varepsilon_3 - \varepsilon_4 - \varepsilon_6$;

If $\tilde{R}_\ell = E_8$:

v) $\alpha = \varepsilon_1 - \varepsilon_2$ and $\vartheta = -\varepsilon_1 + \varepsilon_2 + \varepsilon_6 + \varepsilon_7 + \varepsilon_8$;

vi) $\alpha = \varepsilon_7 - \varepsilon_8$ and $\vartheta = \varepsilon_6 + 2\varepsilon_8 = \varepsilon_8 - \varepsilon_1 - \varepsilon_2 - \varepsilon_3 - \varepsilon_4 - \varepsilon_5 - \varepsilon_7$.

We claim that all $\vartheta$-dual pairs belong to $R_\ell$ and that the space they generate has dimension 5 for the cases i), ii) and v); it has dimension 6 for the cases iii) and iv) and dimension 7 for the case vi). Since in all cases the dimension is strictly less then rank$\tilde{R}_\ell = \ell$, we conclude that the case $R_\ell = E_\ell$ is impossible.

We prove the claim in the cases v) and vi) which occur when $\tilde{R}_\ell = E_8$; in all other cases the proof is similar.

For case v), the $\vartheta$-dual pairs are (up to sign) $(-\varepsilon_1 + \varepsilon_i, \vartheta + \varepsilon_1 - \varepsilon_i)$, where $i = 2, 6, 7, 8$ and they all belong to $R_\ell$. These vectors generate a 5-dimensional vector space. In case vi) the $\vartheta$-dual pairs are $(-\varepsilon_8 + \varepsilon_i, \vartheta + \varepsilon_8 - \varepsilon_i)$, where $i = 1, \ldots, 5$ or 7, and again they are all in $R_\ell$. These vectors generate a 7-dimensional vector space.

**Case (F):** $\tilde{R}_\ell = F_4$.

We have the following possibilities:

i) $(\alpha, \alpha') = (\varepsilon_1 + \varepsilon_2, -(\varepsilon_3 + \varepsilon_4))$;

ii) $(\alpha, \alpha') = (\varepsilon_1 + \varepsilon_2, -\varepsilon_3)$;

iii) $(\alpha, \alpha') = (\varepsilon_1 + \varepsilon_2, -(1/2(\varepsilon_1 - \varepsilon_2 + \varepsilon_3 + \varepsilon_4))$;

iv) $(\alpha, \alpha') = (\varepsilon_1, -\varepsilon_2)$.

Cases i) and iv) are impossible because $\vartheta = \alpha - \alpha'$ should be proportional to no root. The admissible $\vartheta$-dual pairs for case ii) are given by (6.10) and they all belong to $R_\ell$. They generate a 3-dimensional subspace and this is impossible because rank$\tilde{R}_\ell =$ rank$F_4 = 4$. A similar argument is applied for case iii). □
Corollary 6.10. If \( G \) is simple, then the only possibilities for the pair \((R, \tilde{R}_\epsilon)\) are

\[
(A_n, A_3), \quad (A_n, B_3), \quad (B_n, A_3), \quad (B_n, B_3), \quad (B_n, D_4), \quad (D_n, D_4), \quad (D_n, D_n), \quad (E_6, D_5), \quad (E_7, D_6), \quad (E_8, D_5), \quad (E_8, D_7), \quad (F_4, A_3), \quad (F_4, B_3).
\]

Proof. If \( R \) is the root system of the simple Lie group \( G \) and \((\alpha, \alpha')\) is a \( \vartheta \)-dual pair in \( R_\epsilon \), then the arguments used in the proof of Lemma 6.9 give the result. \( \square \)

Lemma 6.11. Let \( \tilde{R}_o = R_o \cap \tilde{R}_\epsilon, R'_o = R_o \setminus \tilde{R}_o \) and \( \alpha, \alpha' \in R_\epsilon \) be a \( \vartheta \)-dual pair. Then

\[ S(\alpha, \alpha') = R_o \cup R_o(\alpha) \cup R_o(-\alpha') \cup R^+_J \]  

is a closed parabolic subsystem of \( R \).

Proof. a) When \( \text{rank} \tilde{R}_\epsilon = 2 \) the claim is trivial.

If \( \tilde{R}_\epsilon = B_3 \), we may assume that \( \alpha = \varepsilon_1 + \varepsilon_2, \alpha' = -\varepsilon_3 \) and \( \vartheta = \varepsilon_1 + \varepsilon_2 + \varepsilon_3 \). Hence

\[ \tilde{R}_o = \tilde{R}_\epsilon \cap \{ \vartheta \}^\perp = \{ \varepsilon_i - \varepsilon_j, \; i, j = 1, \ldots, 3 \} . \]

By Lemma 6.6 (4),

\[
\{ \pm \varepsilon_i, \pm \varepsilon_j \} + \tilde{R}_o \cap R = \{ \pm (\varepsilon_i + \varepsilon_j), \; i, j = 1, \ldots, 3 \} \subset R_\epsilon.
\]

Since \( \tilde{R}_\epsilon = \tilde{R}_o \cup \{ \pm (\varepsilon_i + \varepsilon_j), \; i, j = 1, \ldots, 3 \} \), the claim is proved for this case.

If \( \tilde{R}_\epsilon = D_\epsilon \), the argument is similar. In particular, if \( \vartheta = 2\varepsilon_1 \), one obtains that \( \tilde{R}_o = D_{\epsilon - 1} = \{ \pm \varepsilon_i \pm \varepsilon_j, \; i, j > 1 \} \) and \( R_\epsilon = \{ \pm \varepsilon_1 \pm \varepsilon_i \} \).

b) follows directly from a).

c) The closeness of \( R_Q \) and \( R_P \) follows from Lemma 6.6 (4) and (5) and from point b). The last statement is obvious.

d) The first claim follows from the facts that \( \tilde{R}_\epsilon = \text{span}_\mathbb{Z}(R_\epsilon) \cap R \) and \( (R_o + R_\epsilon) \cap R \subset R_\epsilon \). This implies that \( g(\tilde{R}_\epsilon) \) is an ideal of the semisimple Lie algebra \( g(R_Q) \) and from this also the second claim follows.

e) By point b), \( R_o(\alpha) \cup R_o(-\alpha') \subset R_\epsilon \) and hence \( R_o \cup R_o(\alpha) \cup R_o(-\alpha') \subset R_Q \) and \( S(\alpha, \alpha') \subset R_P = R_Q \cup R^+_J \). Since \( R_Q \) corresponds to a reductive part of the parabolic subalgebra \( g(R_P) \) and \( R^+_J \) corresponds to the nilradical, it follows that
the following $\alpha$

Proof. From $(S(\alpha, \alpha') + R_+^J) \cap R \subset R_+^J$. By d), it remains to check that $R_o(\alpha) \cup R_o(-\alpha)$ is a closed subsystem.

In case $\tilde{R}_e = 2A_1 = D_2$, we have that $R_o(\alpha) \cup R_o(-\alpha) = \{\alpha, -\alpha'\}$ and hence the claim is trivial.

In case $\tilde{R}_e = D_\ell, \ell > 2$, we may assume that $\vartheta = 2\varepsilon_1, \alpha = \varepsilon_1 + \varepsilon_2, \alpha' = -(\varepsilon_1 - \varepsilon_2)$. Then $\tilde{R}_o = \{\pm\varepsilon_i \pm \varepsilon_j, 1 < i, j\}$ and

$$R_o(\alpha) = \{\varepsilon_1 \pm \varepsilon_i, 1 < i\} = R_o(-\alpha')$$

(6.12)

and the conclusion follows. In case $\tilde{R}_e = B_3$, then $\vartheta = \varepsilon_1 + \varepsilon_2 + \varepsilon_3, \alpha = \varepsilon_1 + \varepsilon_2$ and $\alpha' = -\varepsilon_3$. Then $\tilde{R}_o = \{\pm(\varepsilon_i - \varepsilon_j)\}$ and

$$R_o(\alpha) = \{\varepsilon_i + \varepsilon_j\}, \quad R_o(-\alpha') = \{\varepsilon_i\}$$

(6.13)

and again the conclusion follows. $\square$

Since $g(R_+^J)$ is the nilradical of the parabolic subalgebra $g(R_+)$, we may choose an ordering of the roots such that the positive root system $R_+^\ell$ contains $R_+^J$. In the following $\alpha$ denotes the maximal root in $R_\ell$ w.r.t. this ordering and $\alpha'$ is its associated $\vartheta$-dual root.

**Proposition 6.12.** The orthogonal complement $m_C$ to $\mathfrak{k}_C$ in $g_C$ admits the following $\mathfrak{t}_C$-invariant decomposition:

1. if $\tilde{R}_e = B_3$ or $D_2 = A_1 + A_1$, then

$$m_C = e + m_+^J + m_-^J = (m(\alpha) + m(\alpha') + \bar{m}(\alpha) + \bar{m}(\alpha')) + m_+^J + m_-^J,$$

(6.14)

2. if $\tilde{R}_e = D_\ell$, then

$$m_C = e + m_+^J + m_-^J = (m(\alpha) + m(\alpha')) + m_+^J + m_-^J$$

(6.15)

where $m(\alpha)$ and $m(\alpha')$ are irreducible $\mathfrak{k}_C$-moduli with highest weights $\alpha, \alpha'$, which are equivalent and irreducible as $\mathfrak{t}_C$-moduli.

In terms of this decomposition, the holomorphic subspace $m^{10}$ of the CR structure $(D_2, J)$ (up to sign) is of the form

1. if $\tilde{R}_e = B_3$ or $D_2 = A_1 + A_1'$

$$m^{10} = (m(\alpha) + tm(\alpha')) + \bar{m}(\alpha) + \frac{1}{t}m(\alpha') + m_+^J,$$

(6.16)

(2) if $\tilde{R}_e = D_\ell$

$$m^{10} = (m(\alpha) + tm(\alpha')) + m_+^J$$

(6.17)

for some $t \in \{x \in \mathbb{C} : 0 < |x| < 1\} = D \setminus \{0\}$.

Proof. From $(R_o + \alpha) \cap R \subset R_\ell$ and the definition of $\alpha$, the root $\alpha$ is the maximal weight of the $\mathfrak{t}_C$-module in $m_C$ which contains $E_\alpha$. Moreover since $\alpha'$ is $\vartheta$-congruent to $\alpha$, then also $\alpha'$ is the maximal weight of an $\mathfrak{t}_C$- and hence $\mathfrak{t}_C$-module, and the
\( \mathfrak{f}^C \)-moduli \( m(\alpha) \) and \( m(\alpha') \) are equivalent. By Lemma 6.11 b), it follows that the subspace \( \mathfrak{e} \), spanned by the root vectors \( E_\gamma, \gamma \in R_\varepsilon \), is given by

\[
\mathfrak{e} = m(\alpha) + m(\alpha') + \overline{m(\alpha)} + \overline{m(\alpha')}.
\]

Moreover if \( \tilde{R}_\varepsilon = D_\varepsilon, \ell > 2, R_\varepsilon(\alpha) = R_\varepsilon(-\alpha') \) (see (6.12)) and hence \( m(\alpha) = \overline{m(\alpha')} \) (see also Table 3 in the Appendix).

From Lemma 6.1 and the remark in the second to the last point of §6.1, we obtain that the holomorphic subspace \( m^{10} \) is of the form

\[
m^{10} = (m(\alpha) + tm(\alpha')) + m^+_J
\]

when \( \tilde{R}_\varepsilon = D_\varepsilon, \ell > 2, \) and of the form

\[
m^{10} = (m(\alpha) + tm(\alpha')) + (\overline{m(\alpha)} + \overline{sm(\alpha')}) + m^+_J
\]

when \( \tilde{R}_\varepsilon = B_3 \) or \( D_2 = A_1 + A_1 \), for some \( t, s \neq 0 \). By exchanging \( m^{10} \) with \( m^{01} \) (which corresponds to changing the sign of \( J \)) we may assume that \( |t| \leq 1 \). Using the integrability condition and the assumption that \( \vartheta = \alpha - \alpha' \notin R \), we have

\[
[E_\alpha + tE_{\alpha'}, E_{-\alpha} + sE_{-\alpha'}] = H_\alpha + tsH_{\alpha'} \in m^{10} + \mathfrak{t}^C
\]

and therefore \( H_\alpha + tsH_{\alpha'} \in \mathfrak{t}^C \). Using (3.1) we get

\[
0 = \vartheta(H_\alpha + tsH_{\alpha'}) = \langle \vartheta|\alpha > + ts < \vartheta|\alpha' > .
\]

So

\[
s = \frac{1}{t} < \vartheta|\alpha > < \vartheta|\alpha' > .
\]

If \( \tilde{R}_\varepsilon = 2A_1 \), it is immediate to check that \( < \vartheta|\alpha > = 2 = < \vartheta|\alpha' > . \) In case \( \tilde{R}_\varepsilon = B_3 \), we may assume that \( \vartheta = \varepsilon_1 + \varepsilon_2 + \varepsilon_3, \alpha = \varepsilon_1 + \varepsilon_2 \) and \( \alpha' = -\varepsilon_3 \). Hence again \( < \vartheta|\alpha > = < \vartheta|\alpha' > \) and this shows that in both cases \( s = 1/t \).

Finally, the condition \( m^{10} \cap m^{01} = \{0\} \) implies that the vectors \( E_\alpha + tE_{\alpha'} \) and \( E_{-\alpha} + sE_{-\alpha'} = E_\alpha + \frac{1}{t}E_{\alpha'} \) are linearly independent, and hence \( |t| \neq 1 \). □

Lemma 6.13.

1. Let \( q^C = \mathfrak{t}^C + \mathfrak{e} \) and \( p = q^C + m^+_J \). Then \( p \) is a parabolic subalgebra of \( g^C \), with reductive part \( q^C \) and nilradical \( m^+_J \). Moreover, if \( Q \) is the connected subgroup of \( G \) with Lie algebra \( q = q^C \cap g \), then \( F_2 = G/Q \) is a flag manifold and \( m^+_J \) is the holomorphic subspace of an invariant complex structure \( J_2 \) on \( F_2 = G/Q \).

2. The subspace \( m^{10}_J = m(\alpha) + m(-\alpha') + m^+_J \) is the holomorphic subspace of an invariant complex structure \( J_1 \) of \( F_2 = G/K \).

3. The natural \( G \)-equivariant projections

\[
\pi : G/L \rightarrow G/Q, \quad \pi' : G/K \rightarrow G/Q
\]

are holomorphic fibrations w.r.t. the CR structure \( (D_\varepsilon, J) \) on \( G/L \), the complex structure \( J_1 \) on \( F_\varepsilon = G/K \) and the complex structure \( J_2 \) on \( F_\varepsilon = G/Q \), respectively. Moreover, the typical fiber \( C = Q/L \) of \( \pi \) is either \( \text{Spin}_7/\text{SU}_3 = S^7 \times S^6 \) or \( \text{SO}_{2\ell}/\text{SO}_{2\ell-2}, \ell > 1 \) and the induced invariant CR structure is primitive.

4. The typical fiber \( C = Q/L \) of \( \pi \) may be equal \( \text{SO}_4/\text{SO}_2 = S^3 \times S^2 \) only if \( G = G_1 \times G_2, \) with each \( G_i \) simple.
Proof. (1) The proof follows from Lemma 6.11 c) and the remark that \( p = g(R_P) + h^C \) and \( q^C = g(R_Q) + h^C \).

(2) We have to check the conditions a) and b) of (4.2). Condition a) is obvious. Condition b) means that \( t^C + m(\alpha) + m(-\alpha') = g(S(\alpha, \alpha')) + h^C \) is a subalgebra. This follows from Lemma 6.11 e).

(3) The first claim follows from Lemma 4.8.

For the second claim, we recall that we have the following decompositions of the Lie algebras \( q^C \) and \( t^C \):

\[
t^C = g(R'_o) \oplus \left(g(\tilde{R}_o) + Z(t^C)\right),
\]

\[
q^C = t^C + \epsilon = g(R'_o) \oplus \left(g(\tilde{R}_e) + Z(q^C)\right).
\]

Since the fiber \( Q/L \) has a non-standard CR structure, the group \( Q' = Q/N \), where \( N \) is its kernel of non-effectivity, is semisimple by Corollary 3.2 and Proposition 4.6. Therefore it has Lie algebra \( q'^C = g(\tilde{R}_e) = B_3 \) or \( D_\ell \). The corresponding stability subalgebra \( t^C = t^C/n^C \) has rank equal to rank \((q'^C) - 1 \) and its semisimple part is \( g(\tilde{R}_o) = A_2 \) or \( D_{\ell-1} \). Hence the fiber \( Q/L = Q'/L' \), considered as homogeneous manifold of the effective group \( Q' \), is either \( Spin_7/SU_3 \) or \( SO_{2\ell}/SO_{2\ell-2} \) (note that \( SO_7 \) does not contain \( SU_3 \)). The manifold \( Spin_7/SU_3 \) can be identified with the unit sphere bundle \( S(Spin_7/G_2) = S(S^7) = S^7 \times S^6 \).

The holomorphic subspace \( m^{10}(Q/L) \) of the CR structure of the fiber \( Q/L \) is of the form \( (m(\alpha) + tm(\alpha')) + (m(\alpha) + 1/tm(\alpha')) \) for some \( t \neq 0 \) and the minimal \( t^C \)-module generated by \( m^{10}(Q/L) \) is \( \epsilon \). By Lemma 4.8, this implies that the CR structure on \( Q/L \) is primitive.

(4) It is sufficient to observe that if \( G \) is simple, the case \( \tilde{R}_e = A_1 \cup A_1 \) cannot occur by Corollary 6.10. \( \square \)

Lemma 6.13 (3) and Proposition 6.12 directly imply Proposition 6.4.

Now it remains to prove Proposition 6.5. Let \( (M = G/L, D_Z, J) \) be a non-standard non-primitive CR manifold with contact form \( \vartheta \) not proportional to any root. We recall that in Lemma 6.13 (3) we defined a complex structure \( J_1 \) on the flag manifold \( F_Z = G/K \), associated with the decomposition \( g^C = t^C + m^{01} + m^{01}_j \).

We also defined another flag manifold \( F_2 = G/Q \), with \( q^C = t^C + \epsilon \), with invariant complex structure \( J_2 \) associated with the decomposition \( g^C = q^C + m^j + m^j_\perp \) and such that the projection \( \pi : (F_2 = G/K, J_1) \to (F_2 = G/Q, J_2) \) is holomorphic. Moreover the CR structure \((D_Z, J)\) on \( G/L \) has the holomorphic subspace defined in (6.16) and (6.17).

The subalgebra \( t^C \) corresponds to the root subsystem \( R_o \), which has the orthogonal decomposition \( R_o = R'_o \cup \tilde{R}_o \), and \( q^C \) corresponds to the root subsystem with the orthogonal decomposition \( R_Q = R'_o \cup \tilde{R}_e = R'_o \cup (\tilde{R}_o \cup \tilde{R}_e) \) (see Lemma 6.11). Moreover there are only three possibilities for the pair of subsystems \((\tilde{R}_e, \tilde{R}_o)\), namely \( (D_2 = 2A_1, \emptyset), (D_\ell), D_{\ell-1}, \ell > 2 \), or \((B_3, A_2)\). However, the following lemma shows that this last case cannot occur.
Lemma 6.14. If \( R_J \neq \emptyset \), then \( \tilde{R}_\ell \neq B_3 \).

In other words, the fiber \( C = Q/L \) of the CRF fibration \( \pi : G/L \to G/Q \) described in Lemma 6.13 (3) cannot be \( Spin_7/SU_3 \) if the base is not trivial.

Proof. Assume that \( \tilde{R}_\ell = B_3 \). Then \( G \) is simple and \( R \) is indecomposable by Lemma 6.8. So \( R \) has type either \( B_n \) or \( F_4 \), because these are the only connected Dynkin graphs which contain a subgraph of type \( B_3 \).

If \( R = F_4 \), using the notation of the Appendix, we may assume that \((\alpha = \varepsilon_2 + \varepsilon_3, \alpha' = -\varepsilon_4)\) is a \( \vartheta \)-dual pair in \( R_\ell \). Since \( \vartheta = \varepsilon_2 + \varepsilon_3 + \varepsilon_4 \), then \(-\varepsilon_4 + \varepsilon_1 \in R_J \), because it is not orthogonal to \( \vartheta \) or \( \varepsilon_1 \) in \( R_o \), moreover \(-\varepsilon_1 \in R_o = R \cap (\vartheta)^\perp \) and hence \(-\varepsilon_4 = (-\varepsilon_4 + \varepsilon_1) - \varepsilon_1 \in R_J \), by Lemma 6.6 (4): contradiction.

Assume now that \( R = B_n \), \( n > 3 \). Then we may assume that \((\alpha, \alpha') = (\varepsilon_1 + \varepsilon_2, -\varepsilon_3)\) is a \( \vartheta \)-dual pair in \( R_\ell \) and hence that \( \vartheta = \varepsilon_1 + \varepsilon_2 + \varepsilon_3 \). Then, as before, we get that \(-\varepsilon_3 + \varepsilon_4 \in R_J \), \(-\varepsilon_4 \in R_o \) and hence that \(-\varepsilon_3 = (-\varepsilon_3 + \varepsilon_4) + (-\varepsilon_4) \in R_J \); contradiction. \( \square \)

Now we construct some special basis \( \Pi \) for \( R \), which we will call good. For any basis \( \Pi \) let

\[
\Pi_o = \Pi \cap R_o , \quad \tilde{\Pi}_o = \Pi_o \cap \tilde{R}_\ell , \quad \tilde{\Pi}_\ell = \Pi \cap \tilde{R}_\ell , \quad \Pi_\ell = \Pi \cap R_\ell .
\]

Then

\[
\tilde{\Pi}_\ell = \Pi_\ell \cup \tilde{\Pi}_o .
\]

A basis \( \Pi \) is called good if

\[
\tilde{R}_o = [\tilde{\Pi}_o] , \quad \tilde{R}_\ell = [\tilde{\Pi}_\ell] , \quad R_o = [\Pi_o] ,
\]

where for any subset \( A \subset \Pi \) we denote \([A] = \text{span}(A) \cap R \).

A good basis exists because \( R_o \cup \tilde{R}_\ell = R_o' \cup \tilde{R}_\ell \) is a closed subset of roots, \( R_o' \) is orthogonal to \( \tilde{R}_\ell \) and \( R_o = R_o' \cup (R_o \cap \tilde{R}_\ell) = R_o' \cup \tilde{R}_o \). In fact, we may take a basis \( \tilde{\Pi}_o \) for \( \tilde{R}_o \), extend it to a basis \( \Pi_\ell \) for \( \tilde{R}_\ell \), add to it a basis for \( R_o' \) and finally extend everything to a basis \( \Pi \) for \( R \).

By the remarks before Lemma 6.14, the pair \((\Pi_\ell, \tilde{\Pi}_o)\) is of type \((D_\ell, D_{\ell-1})\), \( \ell > 2 \), or \((2A_1, \emptyset)\) and it can be represented by the following two graphs

\[
\begin{align*}
2 & \quad 2 & \cdots & \quad 2 & \quad 2 \quad 1 \\
\otimes & & & & & \otimes \\
1 & & -1 & & & 1
\end{align*}
\]

(6.18)

where the subdiagram of \( \tilde{\Pi}_o \) is obtained by deleting the grey nodes. Moreover, by Lemma 6.9, the contact form \( \vartheta \) is the linear combination of the simple roots associated with the nodes of (6.18) and (6.19) with the indicated coefficients. For example, if \((\Pi_\ell, \tilde{\Pi}_o) = (D_\ell, D_{\ell-1})\) and if we use the standard correspondence between nodes and roots, we get

\[
\vartheta = 2(\varepsilon_1 - \varepsilon_2) + \cdots + 2(\varepsilon_{\ell-2} - \varepsilon_{\ell-1}) + (\varepsilon_{\ell-1} - \varepsilon_\ell) + (\varepsilon_{\ell-1} + \varepsilon_\ell) = 2\varepsilon_1 .
\]
Note that if $\ell = 4$, using two permutations of the simple roots corresponding to the end nodes, one gets the other two possible contact forms, namely $\vartheta = \varepsilon_1 + \varepsilon_2 + \varepsilon_3 + \varepsilon_4$ and $\vartheta = \varepsilon_1 + \varepsilon_2 + \varepsilon_3 - \varepsilon_4$.

Remark that a good basis $\Pi$ together with the subsets $\Pi_o$ and $\Pi_e$ completely determines the homogeneous CR manifold $M = G/L$ and the flag manifolds $(F_Z = G/K, J_1)$ and $(F_Z = G/Q, J_2)$. In fact the root systems $R_o = R(K)$ of $K$ and $R(Q)$ of $Q$ are given by $R_o = [\Pi_o]$ and $R(Q) = [\tilde{\Pi}_e = \Pi_o \cup \Pi_e]$ and $I = \mathfrak{k} \cap (\text{ker} \vartheta)$, where $\vartheta$ is defined by (6.18)-(6.19).

Notice also that by definition of good basis

$$R \cap (\vartheta) \perp = R_o = [\Pi_o]$$

and hence that

$$\Pi_o = \Pi \cap (\vartheta) \perp .$$

Any good basis $\Pi$ together with the subsets $\Pi_o$ and $\Pi_e$ can be represented by a painted Dynkin graph $\Gamma = \Gamma(\Pi)$ if we paint the nodes corresponding to the roots of $\Pi_e$ in grey, the nodes of $\Pi_o$ in white and all others in black.

We call such graph $\Gamma$ a painted Dynkin graph associated with the CR manifold $(M = G/L, \mathcal{D}_Z, J)$.

Any associated painted Dynkin graph has the following two properties.

1. It contains a unique proper subgraph $\Gamma_e$ of type (6.18), if it is connected, or of type (6.19), if it is not connected; moreover in this second case, $\Gamma = \Gamma_1 \cup \Gamma_2$ has two connected components and each of them contains exactly one grey node.

2. The black nodes are exactly the nodes which are linked to $\Gamma_e$.

Indeed, (1) follows from definition of good basis, Lemma 6.8 and Lemma 6.2. (2) follows from (6.21).

A painted Dynkin graph which verifies (1) and (2) is called admissible graph.

Let $\Gamma$ be an admissible graph and $\vartheta(\Gamma)$ the corresponding subgraph of type (6.18) or (6.19). We denote by $\vartheta(\Gamma)$ the linear combination of roots associated with the nodes of $\Gamma_e$ as prescribed in (6.18)-(6.19).

An admissible graph $\Gamma$ is called good if

$$[\Pi_o] = R \cap (\vartheta) \perp ,$$

where $\Pi_o$ is the set of simple roots associated with the white nodes of $\Gamma$. Remark that by (6.20) any graph associated with $(M = G/L, \mathcal{D}_Z, J)$ is a good graph. The converse of this statement is also true.

**Lemma 6.15.** Any good graph is a painted Dynkin graph associated to a homogeneous CR manifolds $(G/L, \mathcal{D}_Z, J)$, which have a contact form $\vartheta$ parallel to no roots and where $(\mathcal{D}_Z, J)$ is non-standard and non-primitive.

**Proof.** Let $\Gamma$ be a good graph and $\vartheta(\Gamma)$ the corresponding contact form. As described in the Introduction, $\Gamma$ defines two flag manifolds $F_1(\Gamma) = G/K$ and $F_2(\Gamma) = G/Q$, with invariant complex structures $J_1(\Gamma)$ and $J_2(\Gamma)$, respectively. Denote by

$$g^c = \mathfrak{k}^c + m_{j_1}^{01} + m_{j_1}^{10}, \quad g^c = q^c + m_{j_2}^{01} + m_{j_2}^{10}$$

where $\mathfrak{k}^c$ and $\mathfrak{q}^c$ are the complexified Lie algebras of $K$ and $Q$ respectively.
the corresponding associated decompositions. Consider also the element \( Z = iB^{-1} \circ \vartheta(\Gamma) \). Since the 1-parametric subgroup generated by \( Z \) is closed, by Proposition 3.3 it defines a contact manifold \( (M = G/L, D_Z) \) with \( I = \mathfrak{z} \cap (Z) \). Moreover the fiber \( C = Q/L \) of the fibration \( \pi : G/L \to G/Q \), together with the contact structure induced on \( C \) by \( Z \), is one of the contact manifolds described in Proposition 6.4 admitting a primitive CR structure.

If \( m^{10} \) is the holomorphic subspace of such CR structure, then \( m^{10} = m^{10}_C + m^{10}_J \) is the holomorphic subspace of a non-standard CR structure \( (D_Z, J) \) on \( G/L \) and the associated painted Dynkin graph is exactly \( (\Gamma, \vartheta(\Gamma)) \). In fact, the conditions i) and ii) of Definition 4.1 are immediate. The integrability condition follows from the fact that \( m^{10}_C \) is a holomorphic subspace for a CR structure on \( C = Q/L \) (and hence that \( d^c + m^{10}_C \) is a subalgebra), that \( m^{10}_J \) is the nilradical of the parabolic subalgebra \( q^C + m^{10}_J \), and that \( m^{10}_C \subset q^C \). \( \square \)

Now the classification of homogeneous CR manifolds of the considered type reduces to the classification of good graphs \( \Gamma \).

**Case 1.** \( \Gamma \) is not connected.

In this case \( \Gamma \) is a connected component which corresponds to a root system \( R_i \), and \( R = R_1 \cup R_2 \). Moreover \( \vartheta = \alpha_i - \alpha_2 \), where \( \alpha_i \in R_i \).

We prove that if \( \Gamma \) is good then \( R = A_p \cup A_q \), with \( p + q > 1 \) and that \( \Gamma \) is a CR-graph of type II.

First of all, one can easily check that if one of the connected components \( \Gamma_i \) is not of type \( A_q \), then \( \Gamma \) is not good, that is that there exists a root \( \beta \in R \cap (\vartheta) \perp \) which is not in \( [\Pi_o] \). For example, if \( R_1 = D_q \), we may assume that \( \vartheta = \alpha_1 - \alpha_2 \), where \( \alpha_1 = \varepsilon_1 - \varepsilon_2 \). Then \( \beta = \varepsilon_1 + \varepsilon_2 \in R \cap (\vartheta) \perp \) but it is not in \( [\Pi_o] \).

Assume now that \( R = A_p \cup A_q \). Without loss of generality we may assume that \( \alpha_1 = \varepsilon_k - \varepsilon_{k+1} \), \( \alpha_2 = \varepsilon_{r} - \varepsilon_{r+1} \) are the roots associated with the grey nodes of \( \Gamma_1 \) and \( \Gamma_2 \), respectively. Then \( R \cap (\vartheta) \perp = A_{p-2} \cup A_{q-2} \) and it coincides with \( [\Pi_o] \) if and only if the nodes of the roots \( \alpha_i \) are end nodes. This proves that \( \Gamma \) is good if and only if it is a CR-graph of type II (see Definition 1.7).

**Case 2.** \( \Gamma \) is connected.

In this case, \( \Gamma \) is a good graph only if the type of the pair \( (\Gamma, \Gamma_\varepsilon) \) is one of the following

\[
(A_n, A_3), \quad (B_n, A_3), \quad (D_n, D_4), \quad (E_6, D_5),
\]
\[
(E_7, D_6), \quad (E_8, D_5), \quad (E_8, D_7).
\]

This follows from Corollary 6.10 and the fact that \( (A_n, A_3), (B_n, B_3), (B_n, D_4), (D_n, D_n), (F_4, A_3) \) and \( (F_4, B_3) \) do not correspond to any admissible graph.

We first prove that the cases \( (B_n, A_3), (E_7, D_6), (E_8, D_5) \) and \( (E_8, D_7) \) are not possible.

\( i \) \( (\Gamma, \Gamma_\varepsilon) = (B_n, A_3) \). In this case \( \Gamma \) is of the form

\[
\begin{array}{cccccccc}
\circ & \cdots & \circ & \circ & \circ & \circ & \cdots & \circ \\
\alpha_1 & \alpha_2 & \alpha_3 & & & & & \\
\end{array}
\]

where \( \alpha_1 = \varepsilon_k - \varepsilon_{k+1}, \alpha_2 = \varepsilon_{k+1} - \varepsilon_{k+2} \) and \( \alpha_3 = \varepsilon_{k+2} - \varepsilon_{k+3} \). Then \( \vartheta(\Gamma) = \alpha_1 + 2\alpha_2 + \alpha_3 = \varepsilon_k + \varepsilon_{k+1} - \varepsilon_{k+2} - \varepsilon_{k+3} \) and

\( \Pi_o = \{ \varepsilon_i - \varepsilon_{i+1}, i = 1, \ldots, k - 2; k; k + 2; k + 4, \ldots, n - 1; \varepsilon_n \} \).
However the root $\beta = \varepsilon_{k+1} + \varepsilon_{k+2} \in (\theta(\Gamma))^\perp \cap R$ but it does not belong to $[\Pi_0]$; contradiction.

ii) $(\Gamma, \Gamma_\varepsilon) = (E_7, D_6)$. In this case $\Gamma$ and $\theta(\Gamma)$ are

$$\alpha_1 \circ \alpha_2 \circ \alpha_3 \alpha_4 \alpha_5 \circ \alpha_6 \circ \alpha_7 \circ \cap \alpha_7 , \quad \theta(\Gamma) = 2\varepsilon_1 + \varepsilon_7 + \varepsilon_8 .$$

However, this situation corresponds to no good graph, because the root $\beta = \varepsilon_7 - \varepsilon_8$ is in $\theta(\Gamma)^\perp \cap R$, but it does not belong to $[\Pi_0] = \{(\varepsilon_a - \varepsilon_b, \pm(\varepsilon_a + \varepsilon_b + \varepsilon_7 + \varepsilon_8) , 1 \leq a, b \leq 6 \}$.

iii) $(\Gamma, \Gamma_\varepsilon) = (E_8, D_5)$. Then $\Gamma$ and $\theta(\Gamma)$ are

$$\circ \circ \circ \circ \circ \circ \circ , \quad \theta(\Gamma) = \varepsilon_4 + \varepsilon_5 + \varepsilon_6 + \varepsilon_7 - \varepsilon_8 .$$

One can easily check that the root $\beta = \varepsilon_1 + \varepsilon_2 + \varepsilon_4$ is orthogonal to $\theta(\Gamma)$, but it doesn’t belong to the subsystem

$$[\Pi_0] = \{(\alpha_1, \alpha_2, \alpha_4, \alpha_5, \alpha_6, \alpha_8)\}$$

generated by white roots: contradiction.

iv) $(\Gamma, \Gamma_\varepsilon) = (E_8, D_7)$. Then $\Gamma$ and $\theta(\Gamma)$ are

$$\circ \circ \circ \circ \circ \circ \circ \circ \circ \circ , \quad \theta(\Gamma) = 2\varepsilon_1 + \varepsilon_8 .$$

Also this case is not possible because $\varepsilon_7 - \varepsilon_9 \in R \cap (\theta(\Gamma))^\perp$ but it is not in $[\Pi_0] = \{(\alpha_2, \alpha_3, \alpha_4, \alpha_5, \alpha_6, \alpha_8)\}$.

It remains to describe the good graphs of the following types

1) $(A_n, A_3) , \quad 2) (D_n, D_4) , \quad 3) (E_6, D_5) .

(1) $(\Gamma, \Gamma_\varepsilon) = (A_n, A_3)$.

Assume that $\Gamma_\varepsilon$ is not at an end of $\Gamma$, that is

Then we may assume that $\alpha_i = \varepsilon_{p+i} - \varepsilon_{p+i+1}$. Then $\theta(\Gamma) = \alpha_1 + 2\alpha_2 + \alpha_3 = \varepsilon_{p+1} + \varepsilon_{p+2} - \varepsilon_{p+3} - \varepsilon_{p+4}$ and the root $\beta = \varepsilon_p - \varepsilon_{p+5} \in R \cap (\theta(\Gamma))^\perp$ but it is not in the span of $\Pi_0$; hence the graph is not good. On the other hand one can easily check that the graph

$$\circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ , \quad \theta(\Gamma) = 2\varepsilon_1 + \varepsilon_8 .$$

is good.

(2) $(\Gamma, \Gamma_\varepsilon) = (D_n, D_4)$.
In this case we have two admissible graphs:

\[
\begin{align*}
\alpha_n & \quad \alpha_n \otimes \alpha_{n-1} \quad \alpha_{n-3} \\
\vdots & \quad \vdots \\
\end{align*}
\] (6.23)

\[
\begin{align*}
\alpha_n & \quad \alpha_n \otimes \alpha_{n-1} \quad \alpha_{n-3} \\
\vdots & \quad \vdots \\
\end{align*}
\] (6.24)

Using the standard equipment, we have that if \( \Gamma \) is given by (6.23), then

\[
\vartheta(\Gamma) = \alpha_{n-3} + 2\alpha_{n-2} + \alpha_{n-1} + 2\alpha_n = \varepsilon_{n-3} + \varepsilon_{n-2} + \varepsilon_{n-1} + \varepsilon_n
\]

and \( R \cap (\vartheta(\Gamma))^\perp = D_{n-4} \cup A_3 \). If \( \Gamma \) is given by (6.24), then

\[
\vartheta(\Gamma) = 2\alpha_{n-3} + 2\alpha_{n-2} + \alpha_{n-1} + \alpha_n = 2\varepsilon_{n-3}
\]

and \( R \cap (\vartheta(\Gamma))^\perp = D_{n-1} \).

Since in both cases \([\Pi_o] = A_{n-5} \cup A_3\), the graph (6.24) is not good, while the graph (6.23) is good only when \( n = 5 \).

(3) \((\Gamma, \Gamma_\varepsilon) = (E_6, D_5)\).

Up to isomorphism, we have only one admissible graph

\[
\begin{align*}
\alpha_1 & \quad \alpha_2 \quad \alpha_3 \quad \alpha_4 \quad \alpha_5 \\
\otimes & \quad \otimes \\
\alpha_6 & \\
\end{align*}
\]

Using the standard equipment, we get

\[
\vartheta(\Gamma) = 2(\alpha_1 + \alpha_2 + \alpha_3) + \alpha_4 + \alpha_6 = 2\varepsilon_1 + \varepsilon_6 + \varepsilon .
\]

Then

\[
R \cap (\vartheta(\Gamma))^\perp = \{ \varepsilon_a - \varepsilon_b, \pm(\varepsilon_a + \varepsilon_b + \varepsilon_6 + \varepsilon) , a, b = 2, 3, 4, 5 \} = [\Pi_o] = D_4
\]

and hence the graph is good.

This concludes the classification of good graphs. We proved that the pairs \((\Gamma, \vartheta(\gamma))\) given by all good graphs are exactly the non-special CR-graphs of Definition 1.7. By the remarks before Lemma 6.15 and the Lemmata 6.13 and 6.15, Proposition 6.5 follows.
The notation used in the following Tables is the same of [7]. We recall that the weights of the groups $B_\ell, C_\ell, D_\ell$ and $F_4$ are expressed in terms of an orthonormal basis $(\varepsilon_1, \ldots, \varepsilon_\ell)$ of $\mathfrak{h}(\mathbb{Q})^*$. The weights of the groups $A_\ell, E_7, E_8$ and $G_2$ are expressed using vectors $\varepsilon_1, \ldots, \varepsilon_{\ell+1} \in \mathfrak{h}(\mathbb{Q})^*$ such that

$$\sum \varepsilon_i = 0, \quad (\varepsilon_i, \varepsilon_j) = \begin{cases} \frac{\ell}{\ell+1} & i = j \\ -\frac{1}{\ell+1} & i \neq j \end{cases} \quad (A.1)$$

It is useful to recall that if $\sum a_i = 0$, then $( \sum a_i \varepsilon_i, \sum b_j \varepsilon_j ) = \sum a_i b_i$. For $E_6$, the weights are expressed by vectors $\varepsilon_1, \ldots, \varepsilon_6$, which verify (A.1) with $\ell = 5$, and by an auxiliary vector $\varepsilon$ which is orthogonal to all $\varepsilon_i$ and verifies $(\varepsilon, \varepsilon) = 1/2$.

In Table 1, for any simple complex Lie group $\mathfrak{g}^\mathbb{C}$, we give the corresponding root system $R$, the longest root $\mu$ (unique up to inner automorphisms), the subalgebra $\mathfrak{g}'_0 = C_{\mathfrak{g}^\mathbb{C}}(\mathfrak{g}(\mu))$, the subsystem of roots $R_0$ corresponding to $\mathfrak{g}'_0$, the decomposition into irreducible submodules of the $\mathfrak{g}_0$-module $\mathfrak{g}_1$ which appear in the decomposition (3.2), and the set of roots $R_1 = R^+ \setminus (\mu \cup R_0)$.

For a set of simple roots of $\mathfrak{g}'_0$, we denote by $\{\pi_1, \ldots, \pi_\ell\}$ the corresponding system of fundamental weights and, for any weight $\lambda = \sum a_i \pi_i$, we denote by $V(\lambda)$ the irreducible $\mathfrak{g}'_0$-module with highest weight $\lambda$.

In Table 2, we give the information needed to determine the holomorphic subspaces $m^{10}$ when $\mathfrak{g}^\mathbb{C}$ is a simple Lie algebra and the contact form $\vartheta = -iB \circ Z|_h$ is parallel to a short root.

In Table 3 we give the same information for the cases $\mathfrak{g}^\mathbb{C} = B_3$ or $D_\ell$ and $\vartheta$ proportional to no root and associated with a primitive CR structure.

In both tables we give the root systems $R$, the contact form $\vartheta$, the subalgebra $\mathfrak{l}^\mathbb{C} = C_{\mathfrak{g}^\mathbb{C}}(Z) \cap (Z)^\perp$, the root subsystem $R_0$ of $\mathfrak{l}^\mathbb{C}$ and the list of the highest weights for the irreducible $\mathfrak{l}^\mathbb{C}$-moduli in $m^\mathbb{C}$ ($\mathfrak{l}^\mathbb{C} = C_{\mathfrak{g}^\mathbb{C}}(Z)$). We group the highest weights corresponding to equivalent $\mathfrak{l}^\mathbb{C}$-moduli with curly brackets.

In Table 4 we recall the Dynkin graphs associated with indecomposable root systems and the correspondence used in [7] between nodes and simple roots.
Table 1

| $g$ | $R$ | $\mu$ | $g'_0$ | $R_o$ | $g_1$ | $R_1$ |
|-----|-----|-------|--------|-------|-------|-------|
| $A_\ell$ | $\varepsilon_1 - \varepsilon_j$ | $A_{\ell-2} + \mathbb{R}$ | $\varepsilon_a - \varepsilon_b$ | $V(\pi_1) + V(\pi_{\ell-2})$ | $\varepsilon_{1} - \varepsilon_a, \varepsilon_{\ell-1} + \varepsilon_{1}$ | $2 \leq a < \ell$ |
| $B_\ell$ | $\pm \varepsilon_1, \pm \varepsilon_j, \pm \varepsilon_i$ | $A_1 + B_{\ell-2}$ | $\pm \varepsilon_1 + \varepsilon_2 \pm \varepsilon_a$ | $V(\pi_1) \otimes V(\pi_1')$ | $\varepsilon_1, \varepsilon_2$ | $3 \leq a < \ell$ |
| $C_\ell$ | $\pm \varepsilon_1, \pm \varepsilon_j, \pm \varepsilon_i$ | $2 \varepsilon_1$ | $-\varepsilon_a - \varepsilon_b, \pm \varepsilon_a$ | $V(\pi_1)$ | $\varepsilon_1, \varepsilon_2$ | $2 \leq a \leq \ell$ |
| $D_\ell$ | $\pm \varepsilon_1, \pm \varepsilon_j, \pm \varepsilon_i$ | $A_1 + D_{\ell-2}$ | $\pm \varepsilon_1 + \varepsilon_2 \pm \varepsilon_a$ | $V(\pi_1) \otimes V(\pi_1')$ | $\varepsilon_1, \varepsilon_2$ | $3 \leq a \leq \ell$ |
| $E_6$ | $\varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4, \varepsilon_5, \varepsilon_6$ | $1 \leq i, j, k \leq 6$ | $2 \varepsilon_i$ | $A_5$ | $\varepsilon_1 - \varepsilon_j$ | $V(\pi_1)$ |
| $E_7$ | $\varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4, \varepsilon_5, \varepsilon_6, \varepsilon_7$ | $1 \leq i, j, k, l \leq 8$ | $-\varepsilon_7 + \varepsilon_8$ | $D_6$ | $\varepsilon_a - \varepsilon_b$ | $V(\pi_1)$ |
| $E_8$ | $\varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4, \varepsilon_5, \varepsilon_6, \varepsilon_7, \varepsilon_8$ | $1 \leq i, j, k, l \leq 9$ | $\varepsilon_a - \varepsilon_b$ | $E_7$ | $\pm \varepsilon_1 + \varepsilon_2 \pm \varepsilon_a$ | $V(\pi_1)$ |
| $F_4$ | $\pm \varepsilon_1, \pm \varepsilon_2, \pm \varepsilon_3, \pm \varepsilon_4$ | $1 \leq i, j \leq 4$ | $e_1 + e_2$ | $C_3$ | $\pm \varepsilon_3$ | $V(\pi_1)$ |
| $G_2$ | $\varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4$ | $1 \leq i, j \leq 3$ | $e_1 + e_2$ | $A_1$ | $\pm \varepsilon_3$ | $V(\pi_1)$ |

Table 2

| $g$ | $R$ | $g' = \mathbb{R}[x] \cap \mathbb{C}[x]$ | $R_o$ | highest weights for $m$-grouped into sets of equivalent $\ell$-moduli |
|-----|-----|----------------------|-------|-------------------|
| $B_\ell$ | $\pm \varepsilon_1, \pm \varepsilon_2, \pm \varepsilon_3, \pm \varepsilon_4, \pm \varepsilon_5, \pm \varepsilon_6$ | $1 \leq i, j \leq \ell$ | $e_1$ | $B_{\ell-1}$ | $\pm \varepsilon_a + \varepsilon_b, \pm \varepsilon_a$ | $2 \leq a, b \leq \ell$ |
| $C_\ell$ | $\pm \varepsilon_1, \pm \varepsilon_2, \pm \varepsilon_3, \pm \varepsilon_4, \pm \varepsilon_5, \pm \varepsilon_6$ | $1 \leq i, j \leq \ell$ | $e_1 + e_2$ | $A_1 + C_{\ell-2}$ | $\pm \varepsilon_1 + \varepsilon_2 \pm \varepsilon_a$ | $2 \leq a, b \leq \ell$ |
| $F_4$ | $\pm \varepsilon_1, \pm \varepsilon_2, \pm \varepsilon_3, \pm \varepsilon_4, \pm \varepsilon_5, \pm \varepsilon_6$ | $1 \leq i, j \leq 4$ | $e_1$ | $B_3$ | $\pm \varepsilon_a + \varepsilon_b, \pm \varepsilon_a$ | $2 \leq a, b \leq 4$ |
