Abstract. Previously, we found that anti-DDDED antibodies strongly inhibited in vivo nuclear transport of nuclear proteins and that these antibodies recognized a protein of 69 kD (p69) from rat liver nuclear envelopes that showed specific binding activities to the nuclear location sequences (NLSs) of nucleoplasmin and SV-40 large T-antigen. Here we identified this protein as the 70-kD heat shock cognate protein (hsc70) based on its mass, isoelectric point, cellular localization, and partial amino acid sequences. Competition studies indicated that the recombinant hsc70 expressed in Escherichia coli binds to transport competent SV-40 T-antigen NLS more strongly than to the point mutated transport incompetent mutant NLS. To investigate the possible involvement of hsc70 in nuclear transport, we examined the effect of anti-hsc70 rabbit antibodies on the nuclear accumulation of karyophilic proteins. When injected into the cytoplasm of tissue culture cells, anti-hsc70 strongly inhibited the nuclear import of nucleoplasmin, SV-40 T-antigen NLS bearing BSA and histone H1. In contrast, anti-hsc70 IgG did not prevent the diffusion of lysozyme or 17.4-kD FITC-dextran into the nuclei. After injection of these antibodies, cells continued RNA synthesis and were viable. These results indicate that hsc70 interacts with NLS-containing proteins in the cytoplasm before their nuclear import.

The nuclear import of karyophilic proteins is a selective, mediated process. Proteins enter the nucleus through the nuclear pore complex, a large proteinaceous structure present in the nuclear envelope (Feldherr et al., 1984). The pore complex contains an aqueous channel of approximately 100-Å diam that allows the non-selective passive diffusion of microinjected molecules smaller than ∼40 kD (for reviews see Dingwall and Laskey, 1986; Newport and Forbes, 1987; Gerace and Burke, 1988). But much larger karyophilic proteins, such as RNP (500 kD) and signal-containing immunoglobulin M (900 kD) can also be efficiently transported into the nucleus through nuclear pores (Michaud and Goldfarb, 1992; Yoneda et al., 1992), apparently because the pore channel expands to allow translocation of karyophilic proteins (Akey and Goldfarb, 1989).

Nuclear transport involves at least two steps, binding to the cytoplasmic face of nuclear pores, and subsequent translocation through the nuclear pore complex. The latter step requires ATP (Richardson et al., 1988; Newmeyer and Forbes, 1988), and is inhibited by wheat germ agglutinin (WGA) or antibodies that recognize nucleoporins, a family of nuclear pore proteins that contain unique O-linked N-acetylglucosamine (GlcNAc) residues (Finlay et al., 1987; Yoneda et al., 1987; Featherstone et al., 1988). In vitro studies have indicated that nuclear transport requires multiple cytoplasmic factors (Newmeyer and Forbes, 1990; Adam and Gerace, 1991; Sterne-Marr et al., 1992; Moore and Blobel, 1992) as well as pore complex proteins (Finlay and Forbes, 1990). Recently, Moore and Blobel (1992) demonstrated that the binding and translocation steps are mediated by distinct cytoplasmic fractions.

The selective nuclear import of proteins is directed by short amino acid sequences termed nuclear location signal sequences (NLSs) (for recent reviews see Silver, 1991; Garcia-Bustos et al., 1991). Characteristically, NLSs contain a high proportion of basic amino acids, which are essential for their function. However, there seems to be no strong consensus sequence among the various NLSs identified, although the amino acid sequence of each NLS is specific and critical for its function. For example, point mutations of key basic residues such as ^Lys of SV-40 T-NLS dramatically reduce its nuclear targeting activity (Lanford et al., 1984; Kalderon et al., 1984; Lanford et al., 1988). Saturation kinetics provided an early indication that nuclear import is a receptor-mediated process (Goldfarb et al., 1986). Many attempts have been made to identify NLS receptors. Candidate NLS-binding proteins have been identified by cross-linking (Adam et al., 1989; Yamasaki et
bodies raised against synthetic DDDED peptide. Our strategy
The Journal of Cell Biology, Volume 119, 1992 1048
jected into the cytoplasm of cultured mammalian cells. This
proteins, we focused on a 69-kD nuclear envelope protein
hibited the in vivo nuclear transport of various nuclear pro-
cytoplasmic injection of anti-DDDED antibodies strongly in-
ited several proteins in nuclear fractions. Among these
were found on a 69-kD nuclear envelope protein
(p69) that bound tightly to nucleoplasmin-Sepharose, and
specifically eluted by peptides based on the NLSs of
nucleoplasm and SV-40 T-antigen (Imamoto-Sonobe et al.,
In this study, we purified p69 and found that this protein
is the 70-kD heat shock cognate protein (hsc70). Further-
more, we found that antibodies against hsc70 strongly in-
hibited the nuclear imports of karyophilic proteins when in-
jected into the cytoplasm of cultured mammalian cells. This
inhibition was specific to the mediated import of karyophiles
because these antibodies did not inhibit the diffusion of small
non-karyophilic proteins into the nucleus. After injection of
these antibodies, cells were viable and continued RNA syn-
thesis, indicating that the inhibition was not the result of
pleiotropic physiological effects.

Hsc70 is known as the uncoating ATPase for clathrin-
coated vesicles (Chappell et al., 1986). The heat shock fam-
ily of proteins (hsps) behave as "chaperones," and have been
implicated in promoting protein folding, transport, and as-
sembly in both eucaryotic and prokaryotic systems (for reviews see Lindquist and Craig, 1988; Ellis and van der
Vies, 1991; Gething and Sambrook, 1992). Translocation of
nascent proteins into the ER and mitochondria requires con-
translocation by binding hydrophobic polypeptide domains
following the leader sequences of unfolded nascent polypep-
tides until they can be unloaded at a specific site for transport
or assembly. The characteristics of nuclear transport are due
to a unique transport process through the large aqueous
channels of nuclear pores. The findings that SV-40 T-antigen
NLS can target even 260 Å colloidal gold particles (Feldherr
et al., 1984; Dworetzky et al., 1988), and that mAbs against
nuclear proteins can accumulate in the nucleus by binding
to their antigens in vivo (Tsuneoka et al., 1986; Borner et al.,
Suggest that karyophilic proteins are not unfolded ap-
preciably during their translocation across the nuclear

Materials and Methods

Cell Culture and Cell Labeling

HEL-R66, an established cell line of human embryonic lung cells was cul-
tured, plated for microinjection experiments, and labeled with 3H[uridine as described previously (Imamoto-Sonobe et al., 1990). Histone H1 was purified from calf thymus as described previously (Sanders, 1977). Nucleoplasmin was pu-
ified from Xenopus laevis oocytes as described previously (Imamoto-
Sonobe et al., 1990). BSA was chemically conjugated to synthetic T-peptide
(CPKKKRKVEDP) by use of succinimidyl 4-(p-maleimidophenyl) buty-
rate (SMBP) as described previously (Yoneda et al., 1988). Nucleoplasmin
and hsc70 were conjugated to CNBr-activated Sepharose 4B (Pharma-
cia LKB Biotechnology Inc., Uppsala, Sweden) at a protein concentration of
1 ng/ml.

Partial Purification of p69 from Bovine Liver
Nuclear Envelopes

p69 was partially purified from high-salt detergent extracts of bovine liver
nuclear envelopes, the equivalent fraction of rat liver nuclei in which we
originally detected p69, and the presence of p69 was determined by NLS-
binding assay on nucleoplasmin-Sepharose as previously described (Ima-
mo-Sonobe et al., 1990). Nuclei were isolated from freshly excised bo-
vine liver as described by Imamoto-Sonobe et al. (1988), and crude nuclear
envelopes were isolated using DNase I by the method described by Dwyer
and Blobel (1976). One unit of nuclear envelope was defined as that derived
from one OD₅₆₀ of nuclei. Based on the method described by Snow et al.
(1987), crude nuclear envelopes were treated sequentially with high-salt
buffer (0.5 M NaCl, 0.1 mM MgCl₂, 10% sucrose, 10 mM triethanol-
amine, pH 7.5, 1 mM DTT, 0.2 mM PMSF, 10 μg/ml leupeptin) and low-salt
detergent buffer (2% NP-40, 5 mM MgCl₂, 10% sucrose, 10 mM trietha-
olamine, pH 7.5, 1 mM DTT, 0.2 mM PMSF, 10 μg/ml leupeptin), at an
envelope concentration of 250 U/ml. The final precipitate was extracted
starting material for purification of p69. It was incubated at 37°C for 3 min
and then centrifuged to obtain a Triton X-114 non-partitioned supernatant

Preparation of Peptides, Nuclear Targeting Proteins,
and Affinity Gel

Peptides were synthesized with a model 430A synthesizer (Applied Bio-
systems, Inc., Foster City, CA), and purified by HPLC as described previ-
sely (Imamoto-Sonobe et al., 1990). BSA was chemically conjugated to
synthetic T-peptide (CPKKKRKVEDP) by use of succinimidyl 4-(p-maleimido-
dophenyl) butyrate (SMBP) as described previously (Yoneda et al., 1988).
Nucleoplasmin and hsc70 were conjugated to CNBr-activated Sepharose 4B (Pharma-
cia LKB Biotechnology Inc., Uppsala, Sweden) at a protein concentration of
1 mg/ml.

cia LKB Biotechnology Inc., Uppsala, Sweden) at a protein concentration of
1 mg/ml.
Purification of p69 (Hsc70) from the Cytoplasm of Ehrlich Ascites Tumor Cells

Freshly harvested Ehrlich ascites tumor cells from the abdominal cavity of mice were washed with PBS and lysed in hypotonic buffer A (20 mM Hepes, pH 7.2, 20 mM KCl, 0.1 mM MgCl₂, 0.2 mM PMSF, 10 μg/ml leupeptin, and 0.5 mM NaCl) before incubation with nucleoplasmin-Sepharose. After incubation (1 h at 4°C) the Sepharose was washed with incubation buffer K containing 1 mM T-peptide (CPKTKRKVEDP) and buffer K containing 1 mM mutant T-peptide (CPKKKRKVEDP) and buffer K containing 1 mM mutant T-peptide (CPKTKRKVEDP) and buffer K containing 1 mM mutant T-peptide (CPKKKRKVEDP) and buffer K containing 1 mM mutant T-peptide (CPKTKRKVEDP) and buffer K containing 1 mM mutant T-peptide (CPKKKRKVEDP). For microinjection experiments, affinity-purified antibodies were concentrated in a Centricon 30 (Amicon Corp., Danvers, MA). mAb Q1 was prepared using a synthetic peptide CGGDDD-EDGG (DDDEDeptide) chemically conjugated to keyhole limpet hemocyanin (KLH) by use of SMBP for immunizations, as previously described (Yoneda et al., 1988). Spleen cells from an immunized BALB/c mouse (mAb Q1) were fused with myeloma cells (SP2/0) using polyethylene glycol-4000. Culture supernatants were screened by antibody capture assay in polyvinylchloride plates coated with DDDEDepeptide-conjugated ovalbumin and 125I-anti-mouse IgG (heavy and light chain specific) was used for detections. Hybridomas that reacted with KLH cross-linked only with SMBP were neglected. Of the mAbs against DDDEDeptide, the antibody named Q1 reacted with hsc70 as shown by the radioimmunoblot described above in a hsc70-coated plate. Q1 antibody (Imamoto-Sonobe et al., 1990). For analysis of the NLS-binding activity of the high-salt detergent extracts of nuclear envelopes (see Figs. 1, c, and d, the sample was diluted to 200 U/ml with the incubation buffer K (50 mM Hepes, pH 7.3, 50 mM KCl, 5 mM MgCl₂, 15 mM octylglucoside, 0.5 mM DTT, 10 μg/ml leupeptin, 5 μg/ml pepstatin) before incubation with nucleoplasmin-Sepharose. After incubation (1 h at 4°C), the Sepharose was washed with incubation buffer K, and eluted sequentially with incubation buffer K containing 1 mM mutant T-peptide (CPKTKRKVEDP) and buffer K containing 1 mM T-peptide (CPKTKRKVEDP) and buffer K containing 1 mM T-peptide (CPKTKRKVEDP) and buffer K containing 1 mM T-peptide (CPKTKRKVEDP). Samples were analyzed by SDS-PAGE followed by immunoblotting.
For results in Fig. 6, chromatographically purified recombinant hsc70 was labeled with 125I (3 × 10^6 cpm/µg sp act protein) with enzyme beads (Bio-Rad), and then incubated with nucleoplasmin-Sepharose in incubation buffer K containing 1 mg/ml BSA and 0.25 mM ATP (6 h at 4°C), in the presence of various amounts of wild type T240-peptide (6 h at 4°C), containing a flanking sequence (CYDDEATAQHAAPPKKRRKVED) or its point mutated T240 peptide (CYDDEATAQHAAPPKKKRRKVED). The gel was washed with incubation buffer K containing 0.5 mg/ml ovalbumin and 0.25 mM ATP, and then incubated in the same incubation buffer containing 2 mM nucleoplasmin-peptide (YVKRPAAATKKQAQKKKKLDC; nucleoplasmin NLS) at 4°C for 12 h. Proteins eluted from the gel were analyzed by SDS-PAGE followed by autoradiography.

Sequence Analysis

p69 purified from the cytoplasm of Ehrlich ascites tumor cells (≈2 nmole) was digested with *Achromobacter protease* I (lysylendopeptidase; Wako Pure Chemicals Industries, Ltd., Chiu oku, Osaka) at an enzyme to substrate ratio of 1:100 (mole/mole) in 1 ml of 10 mM Tris-HCl, pH 9.5, at 37°C for 6 h (Tsunasawa et al., 1989). The resulting peptides were separated by HPLC on a μBondasphere column (3.9 × 15 cm, C4, 300 Å; Millipore Corporation, Waters Chromatography, Milford, Massachusetts) with a linear gradient of 0-60% 2-propanol/acetonitrile (7/3, vol/vol) in 0.1% trifluoroacetic acid at a flow rate of 1 ml/min for 60 min. The sequences of five isolated peptides were determined in a gas-phase sequenator (model 477A; Applied Biosystems).

Immunoblotting

Proteins were separated by 10% SDS-PAGE or two-dimensional gel electrophoresis and transferred electrophoretically to nitrocellulose sheets. Western blots were probed with anti-p69 mouse serum (1/300 dilution) or affinity-purified anti-hsc70 rabbit antibodies (5 µg/ml; the specificities of antibodies were confirmed by raising the IgG concentration to 200 µg/ml and showing that no additional protein bands or spots were detected) in buffer containing 20 mM Tris-HCl, pH 7.5, 1% skim milk, and 0.3 M NaCl for 4 h at room temperature after blocking with PBS containing 3% skim milk for 2 h. Mouse and rabbit antibodies were detected with alkaline phosphatase-conjugated goat antibodies to mouse or rabbit IgG (Bio-Rad) by the standard method.

Immunoprecipitations

HeLa cell nuclear envelope proteins (see above) or 125I-hsc70 (described above) was incubated with 25 µg of mouse mAb in 300 µl of a solution of 50 mM Tris-HCl, pH 7.5, 2% NP-40, 0.5 M NaCl, 5 mM MgCl2, 5 mM BSA, 0.2 mM PMSF, and 10 µg/ml leupeptin at 4°C for 1 h. Proteins bound to Q1 were precipitated with rabbit anti-mouse IgM and protein A-Sepharose by incubation for another 1 h after addition of these proteins to the extracts.

Two-dimensional Gel Electrophoresis

This procedure was carried out as described previously (Yoneda et al., 1985).

Results

Identification of Nuclear Envelope 69kD Protein Showing NLS-binding Activity with Hsc70

A rat liver nuclear envelope protein of 69 kD (p69) recognized by anti-DDDED antibodies bound tightly to nucleoplasmin-Sepharose, and was specifically eluted by peptides based on the NLSs of both SV-40 large T-antigen and nucleoplasmin (Imamota-Sonobe et al., 1990). The 69-kD protein in the high-salt detergent extract from bovine liver nuclear envelopes, the equivalent fraction of rat liver nuclei in which we detected p69 (Imamota-Sonobe et al., 1990), showed the same NLS-binding activity. We partially purified p69 from bovine liver nuclear envelopes (Fig. 1 a), and raised mouse antibodies against this protein (Fig. 1 b). As shown in Fig. 1 c, the 69-kD protein detected by the mouse serum in the nuclear envelope extracts was eluted specifically from nucleoplasmin-Sepharose with 1.0 mM T-peptide (transport competent) but only slightly with 1.0 mM mutant T-peptide (transport incompetent). The specific NLS-binding activity of the partially purified 69-kD protein shows that this protein is the bovine homologue of rat p69 (Imamota-Sonobe et al., 1990).

On immunoblotting, this mouse antiserum recognized a protein of 69 kD not only in nuclear envelope fractions but also in cytoplasmic fractions of bovine, mouse, and human cells (data not shown). The protein band of ≈45 kD recognized by the mouse antiserum (see Fig. 1, b and c) was often not detected in cultured cell extracts and its intensity varied in different experiments.

We found that the 69-kD protein was more abundant in rapidly growing cells than in non-dividing cells such as those of liver tissue. Cell fractionation studies showed that most of the 69-kD protein was extracted in the cytoplasmic fraction with hypotonic buffer (Fig. 2). Therefore, using anti-p69 mouse serum as probe, we purified the 69-kD protein from the cytoplasmic fraction of Ehrlich ascites tumor cells extracted with hypotonic buffer (Fig. 3 a). The final preparation migrated as a single component of pI 5.8 on two-dimensional gel electrophoresis (Fig. 3 b). As shown in Fig. 4, the amino acid sequences of five peptides derived from this protein were found to be identical to those of rat 70-kD heat shock cognate protein (hsc70) reported previously (O'Malley et al., 1985). From its mass, isoelectric point, cellular localization, and partial amino acid sequences, we concluded that the 69-kD protein recognized by anti-p69 mouse serum is hsc70.

In further studies, rabbits were immunized with purified hsc70, and antibodies specific to hsc70 were affinity purified with purified hsc70-conjugated Sepharose. Affinity-purified anti-hsc70 antibodies recognized a single protein band of 69 kD in both the cytoplasmic and nuclear envelope fractions on Western blots (Fig. 5 a). The cytoplasmic and nuclear envelope 69-kD proteins recognized by these antibodies migrated as a single component of pI 5.8 on two-dimensional gel electrophoresis (Fig. 5 b).

To confirm that the nuclear envelope-associated 69-kD protein (p69) that showed NLS-binding activity was hsc70, we examined whether highly specific anti-hsc70 antibodies could actually recognize p69. As shown in Fig. 5 c, these antibodies recognized the nuclear envelope 69-kD protein that bound tightly to nucleoplasmin-Sepharose and was specifically eluted with 1.0 mM T-peptide (but only slightly with the same concentration of mutant T-peptide). The protein eluted with peptide detected by these antibodies migrated as a single component of pI 5.8 on two-dimensional gel electrophoresis (Fig. 5 d). Therefore, we concluded that p69, the nuclear envelope 69-kD protein that showed specific NLS-binding activity, is hsc70.

Interaction of Recombinant Hsc70 Expressed in *E. coli* with NLS

We examined the interactions of purified hsc70 with NLS. For this, recombinant hsc70 expressed in *E. coli* was purified by chromatography, iodinated, and incubated with nucleoplasmin-Sepharose in the presence of various amounts of transport competent synthetic SV-40 T-NLS or transport in-

Imamoto et al. Nuclear Protein Transport and Heat Shock Protein 1051
protein concentration of 20 mg/ml completely inhibited the nuclear transports of both nucleoplasmin and T-BSA (Fig. 8, d and h). The concentration of anti-hsc70 antibodies required for complete inhibition varied with the lot of affinity purified antibodies (from 10 to 30 mg/ml). As shown in Fig. 8j, after injection of these antibodies at lower protein concentration, small amounts of nucleoplasmin (and also T-BSA) migrated into the nucleus, indicating that small proportions of the nuclear proteins escaped from inhibition and entered the nucleus. The transport inhibitory activity of these antibodies was blocked by chromatographically purified bacterially expressed recombinant hsc70, confirming that the inhibitory

effect was not caused by contaminating antibodies or proteins (Fig. 9).

Breeuwer and Goldfarb (1990) reported that small non-karyophilic proteins, such as lysozyme, rapidly diffuse into the nucleus, whereas karyophilic proteins that are small enough to diffuse through the nuclear pore, such as histone H1, are complexed in the cytoplasm probably by NLS receptor(s), and that they do not diffuse into the nucleus. So small karyophilic proteins such as histone H1 (21 kD) must accumulate in the nucleus by a receptor mediated import pathway. To determine whether the inhibitory effects of anti-hsc70 antibodies were specific to the mediated nuclear accumulation of karyophilic proteins, we examined the effects of these antibodies on the nuclear imports of small molecules, such as histone H1 (21-kD basic karyophilic protein), lysozyme (14.4-kD basic non-karyophilic protein), and

**Figure 5.** Identification of p69 as Hsc70 with anti-hsc70 rabbit antibodies. Rabbits were immunized with purified hsc70 described in Fig. 3, and antibodies specific to hsc70 were affinity purified with purified hsc70-conjugated Sepharose. (a) Proteins from the supernatant (100,000 g, 60 min) (lane 1) and precipitate (lane 2) of the cytoplasm; DNase I extracts (lane 3); nuclear envelope precipitate (lane 4) from Ehrlich ascites tumor cells were immunoblotted with anti-hsc70 rabbit antibodies and preimmune serum. Samples of 30 μg of proteins were loaded in each lane. (b) Western blots of proteins from total cell extracts (top), cytoplasm (middle) (lane 1 in a), and nuclear envelopes (bottom) (lane 4 in a) of Ehrlich ascites tumor cells separated by two-dimensional gel electrophoresis probed with anti-hsc70 antibodies. (c) NLS-binding assay of hsc70 in the nuclear envelope fraction. Nuclear envelope proteins extracted with high-salt detergent buffer (20 mM MES, pH 6.0, 2% Triton X-100, 0.3 M NaCl, 1 mM EDTA, 10 μg/ml leupeptin, 0.2 mM PMSF) from Ehrlich ascites tumor cell nuclear envelopes were mixed with nucleoplasmin-Sepharose as in Fig. 1 c. Incubation and elution of protein from nucleoplasmin-Sepharose with synthetic peptides were carried out as described under Materials and Methods. Total proteins mixed with nucleoplasmin-Sepharose (lane 1), proteins not bound to nucleoplasmin-Sepharose (lane 2), proteins eluted with 1 mM T-peptide (lane 3), and proteins eluted with 1 mM mutant T-peptide (lane 4) were analyzed by SDS-PAGE followed by immunoblotting probed with anti-hsc70 rabbit antibodies. (d) Materials specifically eluted with 1.0 mM T-peptide from nucleoplasmin-Sepharose (proteins corresponding to Fig. 5 c, lane 4) alone (top), or the same materials mixed with purified hsc70 (bottom) were separated by two-dimensional gel electrophoresis, and immunoblotted with anti-hsc70 antibodies. The material examined migrated as a single protein spot of 69 kD, pl 5.8, and co-migrated with purified hsc70. The molecular weight markers were as for Fig. 2. Arrowheads indicated the position of hsc70.
FITC-dextran (17.4-kD non-karyophilic molecule). Rhodamine (RITC)-labeled histone H1, RITC-lysozyme, or FITC-dextran was injected into the cytoplasm of HEL cells with affinity-purified anti-hsc70 or control IgG. After incubation for 30 min at 37°C, the cells were fixed and the localizations of the labeled molecules were determined by fluorescence microscopy. When co-injected with anti-hsc70, non-karyophilic molecules such as lysozyme and dextran rapidly migrated into the nucleus within 30 min, whereas karyophilic histone H1 was retained in the cytoplasm (Fig. 10). Co-injection of control IgG did not affect the nuclear migrations of these molecules. (Accumulation of nonkaryophilic small molecules in the nucleus, as observed here, is generally observed phenomena) (Breeuwer and Goldfarb, 1990; Yoneda et al., 1987.) These results show that the inhibitory effect of antibodies was reversible and that injected cells were viable, at least with the amounts of the antibodies that could inhibit the nuclear protein import.

Next, we examined the effect of injection of anti-hsc70 on RNA synthesis in the cells. As shown in Fig. 11, the level of [3H]uridine uptake after the injection was almost the same as that by untreated cells (and also of that of cells after injection of normal rabbit IgG). This shows that ATP was not depleted in cells after injection of a concentration of antibodies that inhibited nuclear import. Taken together, these results strongly suggest that a member of 70-kD heat-shock protein plays an important role in mediated nuclear protein import in living cells.

**Discussion**

We have purified a nuclear envelope-associated 69-kD protein (p69) that was originally identified by anti-DDDED antibodies as an NLS-binding protein (Imamoto-Sonobe et al., 1990). The mass, pl, cellular localization, and amino acid
sequences of the purified protein showed that it is hsc70. Hsc70 was recognized by antibody raised against DDDDED-peptide (Fig. 7). Because the primary sequence of hsc70 does not contain the sequence DDDED, this antibody may recognize nonlinear epitopes of the folded hsc70 molecule. Nuclear envelope-associated hsc70, and the purified bacterially expressed recombinant hsc70 indeed showed specific NLS-binding activities (Fig. 5, c and d and Fig. 6). In the previous study, we found that p69 is membrane associated, but is not an integral membrane protein (Imamoto-Sonobe et al. 1988).

Figure 8. Effects of anti-hsc70 antibodies on nuclear transport of nucleoplasmin and SV-40 T NLS-BSA. Affinity-purified rabbit anti-hsc70 antibodies (20 mg/ml in c, d, g, and h, and 15 mg/ml in i and j) or control antibodies (20 mg/ml in a, b, e, and f) were injected with T-BSA (1.5 mg/ml in a, b, c, and d) or nucleoplasmin (0.7 mg/ml in e, f, g, h, i, and j) into the cytoplasm of HEL cells. The cells were then incubated at 37°C for 30 min before fixation. The subcellular locations of injected nuclear proteins were detected by indirect immunofluorescence staining with mouse mAbs to nucleoplasmin or sheep antibodies to BSA, and then with FITC-conjugated antibodies to mouse or sheep IgG. Procedures were as described by Yoneda et al. (1988).
may be present not only in the nuclear envelope but also diffusely throughout the nucleus (Imamoto-Sonobe et al., 1989). The present results indicated that p69 identified previously is hsc70, a protein that is localized diffusely throughout the cytoplasm and the nucleus. Then, why did the original antibodies show predominant nuclear-rim staining instead of diffusive staining throughout the cytoplasm and the nucleus? Two possible explanations can be considered: (a) The original anti-DDDED antibodies may have recognized a specific site (or conformation) of the hsc70 molecule that is "masked" or "unexposed" in the cytoplasm or DNase I supernatant, and thus they may have predominantly recognized a subpopulation of hsc70 that is associated with nuclear envelopes; and (b) the original anti-DDDED antibodies may have recognized several proteins from nuclear envelopes, one of which was p69. If this was the case, nuclear-rim staining would be stronger than diffuse cytoplasmic and nuclear stainings.

The heterogeneity or specificities of hsp70s with their targets are not well understood. Members of 70-kD heat-shock proteins are commonly thought to interact with hydrophobic domains exposed on unfolded or damaged proteins (Pelham, 1986; Beckmann et al., 1990; Flynn et al., 1991). However, the targets of cytosolic hsp70s are not limited to nascent polypeptides or damaged proteins. Hsc70 is reported to interact with a distinct sequence of clathrin light chain LCa (residues 47-71) (DeLuca-Flaherty et al., 1990). Moreover, prp73 (hsc70) is reported to bind to specific peptide sequences (KFERS and related sequences) that target intracellular proteins for lysosomal degradation (Chiang et al., 1989). Our current results indicated that hsc70 interacts with highly positively charged NLSs, and its interaction is apparently more efficient with transport competent NLS than point mutated transport incompetent NLS.

Anti-hsc70 antibodies strongly inhibited the nuclear accumulation of various karyophilic proteins such as nucleoplasm, SV-40 T-antigen NLS bearing BSA, and histone H1. The inhibitory activity of the antibodies was absorbed by chromatographically purified recombinant hsc70 expressed in E. coli. This confirms that transport inhibition was caused by anti-hsc70 antibodies, not by contaminating antibodies against polypeptides not related to hsc70. Most importantly, the inhibition was specific to signal mediated import. These antibodies did not inhibit the diffusive import of nonkaryophilic small molecules, such as small basic protein lysozyme. These results also showed that nuclear pores were not physically obstructed by, for example, antibody-hsc70 complexes. The injection of anti-hsc70, at protein concentrations that completely inhibited nuclear import, did not kill the injected cells because these cells were viable and the effects were reversible. Moreover, the injection of antibodies did not cause depletion of cellular ATP, because RNA synthesis continued normally in the cells after injection of these antibodies. Thus although hsc70 is considered to participate in various cellular functions, we conclude from our results that the inhibition of nuclear transport by anti-hsc70 antibodies is not the result of pleiotropic physiological effects.

A number of NLS-binding proteins have been identified (Adam et al., 1989; Yamasaki et al., 1989; Li and Thomas, 1989; Meier and Blobel, 1990; Lee and Melese, 1989; Silver et al., 1989). The relationships of all these NLS-binding proteins are not yet known, but none of these reported proteins are members of the 70-kD heat-shock protein family. In spite of the use of the same NLS (for example SV-40 T-antigen NLS) as probe, different strategies (cross-linking, ligand blotting, and in our case anti-peptide antibodies) and different experimental conditions have led to the identifica-
Affinity-purified rabbit anti-hsc70 antibodies (20 mg/ml in a, c, and d) or control antibodies (20 mg/ml in b, e, and f) were injected with RITC-labeled histone H1 (a and b). RITC-lysozyme (c and e) or FITC-dextran (d and f). The cells were then incubated at 37°C for 30 min before fixation and the subcellular locations of injected molecules were examined by immunofluorescence microscopy.

Figure 10. Effects of anti-hsc70 on nuclear import of small karyophilic and non-karyophilic molecules. Affinity-purified rabbit anti-hsc70 antibodies (20 mg/ml in a, c, and d) or control antibodies (20 mg/ml in b, e, and f) were injected with RITC-labeled histone H1 (a and b). RITC-lysozyme (c and e) or FITC-dextran (d and f). The cells were then incubated at 37°C for 30 min before fixation and the subcellular locations of injected molecules were examined by immunofluorescence microscopy.

Functional analyses are necessary to define the actual involvements of these proteins in nuclear transport. Adam and Gerace (1991) purified bovine 54–56-kD cytoplasmic NLS-binding proteins that support nuclear import in semi-permeabilized cells. Stochaj and Silver (1992) showed that antibodies against 70-kD cytoplasmic NLS-binding protein inhibit nuclear transport in semi-permeabilized cells. We
have identified hsc70 as an NLS-binding protein. Antibodies against hsc70 inhibited nuclear transport in living cells.

The presence of a number of NLS-binding proteins raises the possibility of the existence of multiple NLS receptors for SV-40 T antigen-like NLS, or since nuclear transport is a multi-step process, the possibility that karyophilic proteins may need to interact with two or more NLS-binding proteins before they are transported into the nucleus. As the present results show that hsc70 has affinity to NLSs, it is interesting to consider the following possibilities for how this protein participates in nuclear transport through interaction with NLSs. First, hsc70 could be one of the multiple NLS-receptors that carries karyophilic proteins from the cytoplasm into the nucleus. Second, hsc70 could promote correct assembly (or disassembly) between NLS and NLS receptors by interacting with NLSs. Third, hsc70 could be the ATPase involved in NLS-dependent dilation of the pore channel. Further studies on factors that co-operate with hsc70 in nuclear transport are required to determine its actual role.

We thank Dr. M. Nakanishi for discussions and reading through this manuscript. We also thank Dr. David S. Goldfarb for discussions and suggestions.

This work was supported by grants from the Ministry of Education, Science and Culture (grant 04259101), and the Science and Technology Agency of Japan.

Received for publication 6 January 1992 and in revised form 4 August 1992.

Note Added in Proof. During submission of this paper, a study by Shi, Y., and J. O. Thomas (1992. Mol. Cell. Biol. 12:2186) was published, which demonstrated that hsp70 and hsc70 support the nuclear import of nucleoplasm in semi-permeabilized cells.
