† These authors have contributed equally to this work.

The biotype El Tor of serogroup O1 and most of the non-O1/non-O139 strains of Vibrio cholerae can produce an extracellular pore-forming toxin known as cholera hemolysin (HlyA). Expression of HlyA has been previously reported to be regulated by the quorum sensing (QS) and the regulatory proteins HlyU and Fur, but lacks the direct evidence for their binding to the promoter of hlyA. In the present work, we showed that the QS regulator HapR, along with Fur and HlyU, regulates the transcription of hlyA in V. cholerae El Tor biotype. At the late mid-logarithmic growth phase, HapR binds to the three promoters of fur, hlyU, and hlyA to repress their transcription. At the early mid-logarithmic growth phase, Fur binds to the promoters of hlyU and hlyA to repress their transcription; meanwhile, HlyU binds to the promoter of hlyA to activate its transcription, but it manifests direct inhibition of its own gene. The highest transcriptional level of hlyA occurs at an OD600 value of around 0.6–0.7, which may be due to the subtle regulation of HapR, Fur, and HlyU. The complex regulation of HapR, Fur, and HlyU on hlyA would be beneficial to the invasion and pathogenesis of V. cholerae during the different infection stages.

Keywords: Vibrio cholerae, regulation, HlyA, quorum sensing, HapR, Fur, HlyU

INTRODUCTION

Vibrio cholerae, a Gram-negative and curved bacterium, is the causative agent of the diarrheal disease cholera (Clemens et al., 2017). This pathogen expresses various key virulence factors, including major ones, such as cholera toxin (CT), toxin co-regulated pilus (TCP), flagellum, and cholera hemolysin (HlyA; Almagro-Moreno et al., 2015; Benitez and Silva, 2016; Clemens et al., 2017). HlyA, an extracellular pore-forming toxin, is expressed in the El Tor biotype and most of the non-O1/non-O139 isolates (Yamamoto et al., 1990a; Singh et al., 2001; Diep et al., 2017). HlyA, an extracellular pore-forming toxin, is expressed in the El Tor biotype and most of the non-O1/non-O139 isolates (Yamamoto et al., 1990a; Singh et al., 2001; Diep et al., 2017). HlyA has been recognized as a virulence determinant in the infant mouse cholera model (Fallarino et al., 2002). Purified HlyA can induce fluid accumulation and a histological change in the mucosa when injected into rabbit ileal loops (Ichinose et al., 1987; Debellis et al., 2009). In vitro studies showed that HlyA...
induces cell vacuolation and apoptosis in cultured mammalian cells (Coelho et al., 2000; Mitra et al., 2000; Figueroa-Arredondo et al., 2001; Chakraborty et al., 2011). HlyA was also strongly suggested to be responsible for lethality, developmental delay, and intestinal vacuoles formation in Caenorhabditis elegans during V. cholerae infection (Cinar et al., 2010; Sahu et al., 2012).

Expression of HlyA was highly induced when V. cholerae was cultured in rabbit ileal loops (Xu et al., 2003). It has also been found to be positively regulated by HlyU, a member of SmtB/ArsR family of transcriptional repressors (Saha and Chakrabarti, 2006). Deletion of hlyU decreased HlyA production but increased LD_{50} in the infant mouse cholera model (Williams et al., 1993). HlyU acts as a dimer that binds to the promoter of hlyA to activate its transcription (Mukherjee et al., 2015). In addition, the quorum sensing (QS) master regulator HapR was shown to be involved in repressing HlyA expression at both the transcriptional and posttranscriptional levels (Tsou and Zhu, 2010). Repression of hlyA by HapR at the transcriptional level was achieved through direct binding of HapR to the hlyA promoter, while that at posttranscriptional level was mediated via the metalloprotease HapA (Tsou and Zhu, 2010). However, as a virulence factor, expression of hlyA should be under the tight control of multiple regulators.

The ferric uptake regulator Fur is a metal-dependent DNA-binding protein that regulates multiple genes related to metabolism and virulence in V. cholerae (Occhino et al., 1998; Davis et al., 2005; Mey et al., 2005; Wyckoff et al., 2007; Davies et al., 2011). A 19 bp palindromic sequence was previously described as the DNA binding box of Fur in V. cholerae (Goldberg et al., 1990). However, the palindromic sequence cannot explain all of the DNA-binding characteristics of Fur. Thus, an enhanced V. cholerae Fur box with a 21 bp palindromic sequence was

Gao et al. Three Regulators Control hlyA Transcription

Frontiers in Microbiology | www.frontiersin.org 2 June 2018 | Volume 9 | Article 1310
constructed based on the ChIP-seq-identified binding sites, but it shares an identical span of bases with the previously predicted (Davies et al., 2011). One Fur box-like sequence, TGAATATCAGTAATTGTTATT, was found within the upstream DNA region of hlyA, suggesting that its transcription might be under the direct control of Fur. In the present study, we showed that the highest transcription of hlyA occurs at early mid-logarithmic growth phase due to the collective and elaborate regulation of HapR, Fur, and HlyU, suggesting that HlyA would only function during the early mid-logarithmic growth phase in V. cholerae. The complex regulatory actions of HapR, Fur, and HlyU on hlyA transcription would be beneficial to the invasion and pathogenesis of V. cholerae.

**MATERIALS AND METHODS**

**Construction of the Mutants and Complementary Mutants**

*Vibrio cholerae* O1 El Tor strain C7258 (Peru, 1991) was used as the wild type (WT) in this study. The deletion mutants of hapR, fur, and hlyU (designated as ΔhapR, Δfur, and ΔhlyU, respectively) were constructed from WT using the suicide plasmid pWM91 by allelic exchange, which was similarly performed as previously described (Wu et al., 2015). To construct the complementary mutants, the entire coding region of each deleted gene was cloned into the pBAD24 vector harboring an arabinose PBAD promoter and an ampicillin resistance gene (Guzman et al., 1995; Sun et al., 2014). After being verified by DNA sequencing, the complementary plasmid for each deleted gene was transferred into the corresponding mutant, yielding the complementary mutant strain ΔhapR/pBAD24-hapR, Δfur/pBAD24-fur, or ΔhlyU/pBAD24-hlyU. In order to counteract the effects of arabinose and ampicillin on bacterial growth, the empty vector pBAD24 was introduced into WT or each mutant to generate WT/pBAD24, ΔhapR/pBAD24, Δfur/pBAD24, or ΔhlyU/pBAD24, respectively (Sun et al., 2014). All the primers used are listed in Table 1.

**Growth Conditions**

The LB broth (1% tryptone, 0.5% yeast extract, and 1% NaCl) was used for *V. cholerae* cultivation. Overnight bacterial cultures were diluted 1:50 into 15 ml of fresh LB broth, and grown under 37°C with shaking at 200 rpm to reach an OD<sub>600</sub> value of 1.0, and then diluted 1:100 into 15 ml of fresh LB broth for the third-round growth, and were harvested at required cell densities. When necessary, the LB broth was supplemented with 100 µg/ml ampicillin, 5 µg/ml chloramphenicol, 100 µg/ml kanamycin, or 0.1% arabinose.

**Hemolytic Activity Assay**

The hemolytic activity of *V. cholerae* strains were tested using the method previously described with slight modifications (Zhang et al., 2017b); 5 µl of the third-round bacterial cultures were transferred onto LB agar containing 5% sheep blood erythrocytes, 100 µg/ml ampicillin, and 0.1% arabinose. The LB blood plates were incubated at 37°C for 20 h.

**Luminescence Assay**

For the lux activity assay (Xu et al., 2010), the promoter DNA region of each target gene was PCR amplified and cloned into the corresponding restriction endonuclease sites of pBBrlux vector harboring a promoterless luxCDABE reporter gene and a chloramphenicol resistance gene. The resulting plasmid was then transferred into WT and mutant strains, respectively. The *V. cholerae* strains transformed with recombinant plasmids were cultivated completely in LB broth at 37°C, and harvested at the

![FIGURE 2](image-url)  
**FIGURE 2** | Cell density-dependent expression of target genes. The promoter DNA region of each target gene was cloned into the pBBrLux vector and then transferred into WT to determine the luminescence activity under various OD<sub>600</sub> values. The bacteria were cultivated completely in LB broth containing the appropriate antibiotics and grown with shaking at 37°C.

![FIGURE 1](image-url)  
**FIGURE 1** | Hemolytic activity of different Vibrio cholerae strains on LB-5% sheep blood agar. After being incubated at 37°C for 48 h, the LB blood plates were photographed. I, II, III, IV, V, VI, and VII represent WT/pBAD24, ΔhlyU/pBAD24, ΔhlyU/pBAD24-hlyU, ΔhapR/pBAD24, ΔhapR/pBAD24-hapR, Δfur/pBAD24, and Δfur/pBAD24-fur, respectively.
required cell densities. The luminescence was measured using an Infinite® 200 Pro NanoQuant (Tecan, Switzerland). The lux activity was calculated as light units/OD_{600}.

**RNA Isolation and Quantitative Real-Time PCR (qRT-PCR)**

Total RNAs were extracted using the TRIzol Reagent (Invitrogen, United States). The cDNAs were generated by using 12 μg of total RNAs and 3 μg of random hexamer primers. The quantitative real-time PCR (qRT-PCR) assay was performed and analyzed as previously described (Gao et al., 2011). The relative mRNA levels were determined based on the standard curve of recA (reference gene) expression for each RNA preparation.

**Preparation of 6x His-Tagged Proteins**

The entire coding region of *hapR*, *fur*, and *hlyU* was amplified and cloned into the plasmid pET28a (Novagen, United States), respectively. The resulting plasmids encoding His-tagged proteins were transferred into *Escherichia coli* BL21 λDE3 cells for protein expression (Kleber-Janke and Becker, 2000). The methods for purification of His-tagged proteins were done as previously described (Gao et al., 2008; Zhang et al., 2012). The eluted His-tagged proteins were dialyzed and then concentrated to a final concentration of 0.3–0.6 mg/ml. The purity of purified proteins was analyzed by SDS-PAGE.

**DNase I Footprinting**

The procedures for DNase I footprinting assay and DNA sequencing were carried out as previously described (Gao et al., 2017; Osei-Adjei et al., 2017; Zhang et al., 2017b). Briefly, upon being incubated with the increasing amounts of His-tagged protein, the FAM (or HEX)-labeled DNA probes were digested by the optimized RQ1 RNase-Free DNase I (Promega). The digested DNA fragments were then analyzed using an ABI 3500XL DNA Genetic analyzer with GeneMarker software 2.2, while the DNA sequencing products were surveyed with Sequence Scanner software v1.0.

**Primer Extension Assay**

The primer extension assay was performed as previously described with slight modifications (Gao et al., 2011). Briefly, 12 μg of total RNA was annealed with 1 pmol of 5’-HEX-labeled

---

**FIGURE 3 | Regulation of *hlyU* and *hlyA* by HlyU.** The luminescence assay (A) was done as Figure 2. (B) qRT-PCR. The relative mRNA level of fur was compared between ΔhlyU and WT. (C) DNase I footprinting. The promoter fragment of each target gene was labeled with FAM or HEX, incubated with increasing amounts of purified His-HlyU (Lanes-I, II, and III contain 0, 4.06, and 12.12 pmol, respectively), and then subjected to DNase I footprinting assay. The results were analyzed using an ABI 3500XL DNA analyzer. The protected regions are boxed and marked with positions. The negative and positive numbers indicate the nucleotide positions relative to the translation start site (+1) of each target genes, respectively.
reverse oligonucleotide primer to generate cDNAs using the Primer Extension System (Promega) according to the manufacturer's instructions. The primer extension products and sequencing materials were analyzed using the same methods as that of the DNase I footprinting assay.

**Experimental Replicates and Statistical Methods**

The presented data of hemolytic activity assay, DNase I footprinting, and primer extension were done at least two independent times. The luminescence assay and qRT-PCR were performed with at least three independent bacterial cultures, and the values were expressed as the mean ± SD. Paired Student's t-test was used to calculate statistically significant differences, and \( p < 0.01 \) was considered to indicate statistical significance.

**RESULTS**

**HapR and Fur Represses the Hemolytic Activity of *Vibrio cholerae***

The hemolytic activities against sheep blood erythrocytes were compared between WT/pBAD24, mutant (ΔhapR/pBAD24, Δfur/pBAD24, or ΔhlyU/pBAD24), and the complementary mutant (ΔhapR/pBAD24-hapR, Δfur/pBAD24-fur, or ΔhlyU/pBAD24-hlyU) strains (Figure 1). The results showed that the WT/pBAD24 and all of the complementary mutants exhibit α-type hemolysis, but ΔhapR/pBAD24 and Δfur/pBAD24 manifest β-type hemolysis. Thus, both HapR and Fur strongly inhibited the hemolytic activity of *V. cholerae*. Although the ΔhlyU/pBAD24 strain also exhibited α-type hemolysis, its colony was much dull than that of WT/pBAD24 or ΔhlyU/pBAD24-hlyU, which is consistent with HlyU activation of hlyA transcription. Taken together, these results indicated that the transcription of hlyA would be under the negative control of HapR and Fur, but under the positive regulation of HlyU.

**Transcription of hapR, fur, hlyU, and hlyA Were All Cell Density-Dependent**

The luminescence reporter assay was employed to measure the transcription changes of hapR, fur, hlyU, and hlyA during the growth periods of the strains (Figure 2). The transcription levels of all of the four genes were increased but then reduced with the increase of cell density. In addition, the transcriptional activity of each of the four genes could be detected at all cell densities. However, the highest transcription of hapR occurred at an OD\(_{600}\) value of around 1.0, while that of fur, hlyU, and hlyA appeared
at an OD\textsubscript{600} value of around 0.6–0.7. Thus, the \textit{V. cholerae} cells were harvested at the OD\textsubscript{600} value of about 1.0 and 0.6 for characterizing HapR- and Fur/HlyU-mediated gene regulation, respectively. Moreover, the cell density-dependent transcription of \textit{fur} and \textit{hlyU} suggests that their expression would be under the control of QS.

**FIGURE 5** | Negatively regulation of \textit{hlyU} and \textit{hlyA} by Fur. The luminescence assay (A) was done as Figure 2. The qRT-PCR (B) and DNase I footprinting assay (C) were done as Figure 3. Lanes-I, II, and III contain 0, 2.95, and 8.85 pmol His-Fur, respectively.

**FIGURE 6** | Transcription start sites of \textit{hlyA} and \textit{hlyU}. A 5'-HEX-labeled oligonucleotide primer was designed to be complementary to the RNA transcript of each target gene. The primer extension products were analyzed with an ABI 3500XL DNA Genetic analyzer. The transcription start sites are marked with asterisks and positions.
HlyU Activates hlyA Transcription but Represses Its Own Gene

As determined by the luminescence assay (Figure 3A), the promoter activity of hlyA in ΔhlyU was much lower relative to that in WT, whereas that of luminescence under the control of hlyU promoter in ΔhlyU was much higher than that in WT, suggesting the positive and negative regulation of hlyA and hlyU by HlyU, respectively. The qRT-PCR assay further confirmed the positive correlation between HlyU and hlyA transcription in V. cholerae (Figure 3B). The DNase I footprinting assay showed that His-HlyU protected a single region, i.e., −563···−627 or −99···−155, for hlyA or hlyU promoter, respectively, against DNase I digestion in a dose-dependent manner (Figure 3C). Taken together, these results suggested that HlyU acts as a transcriptional activator of hlyA but serves as a repressor of its own gene in V. cholerae.

Negative Regulatory Actions of HapR and Fur on hlyU and hlyA

The results of luminescence assay showed that the promoter activities of hlyU and hlyA in both ΔhapR and Δfur were much higher relative to that in WT (Figures 4A, 5A).
qRT-PCR assay indicated that the transcriptional levels of hlyU and hlyA significantly increased in ΔhapR and Δfur relative to WT (Figures 4B, 5B). The DNase I footprinting assay disclosed that His-HapR protected two different DNA regions for each promoter against DNase I digestion (Figure 4C), while His-Fur only protected a single region for each promoter (Figure 5C). Taken together, both HapR and Fur repressed the transcription of hlyU and hlyA in a direct manner.

Identification of the Transcription Start Sites for hlyA and hlyU

Two transcriptions start sites of fur have been previously reported in V. cholerae (also seen in Figure 8; Litwin et al., 1992; Lam et al., 1994). In the present work, the primer extension assay was employed to map the transcription start sites of hlyA and hlyU. The assay detected only one transcription start site for each gene located at 287 bp upstream of hlyA and 432 bp upstream of hlyU, respectively (Figure 6).

HapR Represses fur Transcription

The recombinant pBBRlux plasmid that contains the promoter-proximal region of fur and a promoterless luxCDABE reporter gene was transferred into ΔhapR and WT, respectively, to test the action of HapR on the promoter activity of fur. As shown in Figure 7A, the promoter activity of fur in ΔhapR was much higher relative to that in WT, indicating the negative correlation of HapR and fur transcription in V. cholerae. As further determined by the qRT-PCR assay (Figure 7B), the mRNA level of fur was significantly enhanced in ΔhapR relative to WT. The results of in vitro DNase I footprinting (Figure 7C) demonstrated that His-HapR protected a single region from 238 to 558 bp upstream of fur against DNase I digestion in a dose-dependent manner. Taken together, HapR directly and negatively regulates the transcription of fur in V. cholerae.

DISCUSSION

Although iron-, Fur-, HapR-, and HlyU-dependent expression of hlyA has been previously reported in V. cholerae (Stoeber and Payne, 1988; Williams et al., 1993; Tsou and Zhu, 2010; Mukherjee et al., 2015), the detailed regulatory mechanisms need to be further illustrated. In this study, we showed that the transcription of hlyA was regulated coordinately by HlyU, HapR, and Fur in V. cholerae El Tor biotype (Figure 8). At the late mid-logarithmic growth phase (OD₆₀₀ ≈ 1.0), the highly expressed HapR bound to the promoters of fur, hlyU, and hlyA to repress their transcription. At the early mid-logarithmic growth phase (OD₆₀₀ ≈ 0.6), the highly expressed Fur bounds to the promoters of hlyU and hlyA to repress their transcription; meanwhile, HlyU bounds to the promoters of hlyA and hlyU to activate and inhibit their transcription, respectively. The highest transcriptional level of hlyA occurred at an OD₆₀₀ value of about 0.7 due to the tight regulation of HapR, Fur, and HlyU, suggesting that HlyA would function at the early mid-logarithmic growth phase in V. cholerae.

Vibrio vulnificus secretes a potent hemolysin (VvhA) sharing homologous regions with HlyA (Yamamoto et al., 1990b). VvhA exhibits strongly cytolytic and hemolytic activities and may contribute to the bacterial invasion and causes vasodilatation (Kim et al., 1993; Kook et al., 1996; Elgaml and Miyoshi, 2017). Vibrio vulnificus SmcR, a HapR homolog, directly represses the expression of hlyU and vvhA, while HlyU directly activates vvhA transcription (Shao et al., 2011; Wen et al., 2012). Deletion of hlyU resulted in the loss of cytotoxicity and reduced VvhA production in the smcR mutant (Shao et al., 2011). The double mutant of smcR and hlyU regained cytotoxicity and hemolytic activity when hns was further deleted (Shao et al., 2011). HlyU seems act as an anti-repressor of H-NS in the regulation of the virulence genes in V. vulnificus (Liu et al., 2009). In addition, it has been shown that iron represses vvhA transcription via Fur, which represses vvhA transcription in the presence of iron through the protein–promoter DNA association (Kim et al., 2009). The binding site of Fur overlaps with that of SmcR but with a higher affinity than SmcR (Wen et al., 2012). Moreover, Fur has been shown to be involved in the regulation of smcR transcription in V. vulnificus (Kim et al., 2013; Wen et al., 2016). However, V. cholerae Fur seems to have no regulatory activity on hapR transcription (data not shown), suggesting that the regulation of the QS regulator gene by Fur may depend on the bacterial growth conditions. Nevertheless, the conservative regulatory mechanisms might be employed to tightly control the HlyA production in V. vulnificus and V. cholerae.

The transcription of hlyA, fur, and hlyU was stimulated at the early mid-logarithmic growth phase but repressed at both low cell density (LCD) and high cell density (HCD; Figure 2), suggesting that some unknown regulators can repress their transcription at LCD. AphA has been considered as the bottom master regulator of V. vulnificus.
of QS operating at LCD (Ng and Bassler, 2009; Ball et al., 2017). The DNA binding box of AphA has been identified as an inverted repeat of ATATGC with a 6-nt centered spacer, i.e., ATATGCA-N6-TGCAT (Sun et al., 2012). An AphA box-like sequence (ATACCTCCTCTTTAATCTCAT) was detected within the promoter of hlyU but was not found in the other two promoters (Figure 9). Thus, the transcription of hlyU would be under the direct control of AphA. The asymmetric production of AphA and HapR orthologs coupled with their combined inhibition of downstream targets has been observed in other vibrios (Van Kessel et al., 2013; Zhang et al., 2017a). For example, in Vibrio harveyi, both AphA and LuxR bound to the promoters of the type III secretion system (T3SS) genes to repress their transcription, resulting in the highest expression levels of T3SS occurring at LCD-to-HCD transition (Van Kessel et al., 2013); in Vibrio para-haemolyticus, ToxR coordinates with AphA and OpaR to repress T6SS1, leading to the highest expression of T6SS1 occurring at the mid-logarithmic growth phase (Zhang et al., 2017a). However, the detailed regulatory mechanisms of AphA or other additional factors on hlyA transcription in V. cholerae need to be further investigated.

The organization of fur, hlyU, and hlyA promoters was reconstructed herein, by collecting the data of translation/transcription start sites, promoter −10 and −35 elements, HapR/Fur/HlyU binding sites, AphA box-like sequence, and Shine-Dalgarno (SD) sequences (ribosomal binding sites; Figure 9). One HapR binding site was detected in the upstream of fur and hlyA, respectively, and each overlaps the core −10 element; two HapR binding sites for hlyU were detected and both of them were located downstream of the transcription start site. Thus, the binding of HapR would block the entry or elongation of the RNA polymerase to repress the transcription of the target genes. Both the Fur and HlyU sites for hlyU are located downstream of the transcription start site, indicating that the repression mechanisms of hlyU by Fur and HlyU would be similar to that by HapR. Notably, the Fur site for hlyU overlaps the HapR site 1, while HlyU site overlaps the HapR site 2. Thus, there may be a competitive binding activity between HapR and Fur or HlyA in the binding of the hlyU promoter. Although the binding site of Fur to hlyA is located upstream of the transcription start site, it overlaps with that of HlyU. Thus, the binding of HapR would block the binding of HlyU, which acts as a transcriptional activator of hlyA in V. cholerae.

**CONCLUSION**

This work reports that QS coordinates with HlyU and Fur to regulate hlyA transcription in V. cholerae, leading
to the highest transcription of hlyA occurring at the early mid-logarithmic growth phase when bacteria cells are grown in LB broth. Therefore, we propose that at the early or middle stage of infection, *V. cholerae* produces high amount of HlyA in the small intestine, which promotes the bacterial invasion and pathogenesis, and contributes to the watery diarrhea; at the end of the infectious cycle, since HapR is highly expressed, it activates the protease production and inhibits the biofilm formation, to detach the mutual aggregation of *V. cholerae* cells in the initial infection sites in the intestine. Meanwhile, the expression of CT decreases, and therefore the shift to lower expression of HlyA may have a similar response of CT.

HG, JX, YZ, and BK conceived the study and designed experimental procedures. XL, JLi, JLo, HZ, BD, and QS performed the experiments and carried out data analysis. HG, YZ, and BK wrote the paper.
