Gaussian heat kernel upper bounds via the Phragmén–Lindelöf theorem

Thierry Coulhon and Adam Sikora

Abstract
We prove that in the presence of $L^2$ Gaussian estimates, the so-called Davies–Gaffney estimates, on-diagonal upper bounds imply precise off-diagonal Gaussian upper bounds for the kernels of analytic families of operators on metric measure spaces.

1. Introduction

The study of properties of second-order self-adjoint differential operators often depends on Gaussian upper bounds for the corresponding heat kernel, that is, the kernel of the semigroup generated by these operators. Gaussian heat kernel upper bounds play a crucial role in the proofs of many results concerning boundedness of the Riesz transform, convergence of Bochner–Riesz means or boundedness of spectral multipliers, as well as problems related to maximal regularity properties (see, for example, the articles [1,2,4,15,16,20–23,31,38,47] and the monograph [50]). If $p_t(x,y)$ denotes the heat kernel corresponding to a second-order differential elliptic or sub-elliptic operator, then the typical Gaussian heat kernel upper bound is of the form

$$0 \leq p_t(x,y) \leq C V(x,\sqrt{t}) \exp\left(-\frac{d^2(x,y)}{Ct}\right)$$

(1.1)

for all $t > 0$, $x, y$ ranging in the space where the operator acts, for an appropriate function $V$. For instance, if $p_t$ is the kernel corresponding to the Laplace–Beltrami operator on a Riemannian manifold then, at least in some favorable cases, one expects $V(x, r)$ to be equal to the volume of the geodesic ball of radius $r$ and centered at $x$, and $d$ denotes the Riemannian distance. In the standard approach, proofs of Gaussian estimates are divided into two steps. First, one obtains on-diagonal estimates

$$p_t(x,x) \leq \frac{C}{V(x,\sqrt{t})}$$

(1.2)

for all $t, x$. Then, the theory says that one can automatically improve on-diagonal bounds by adding the Gaussian factor $\exp\left(-\frac{d^2(x,y)}{Ct}\right)$ and obtain this way Gaussian bounds (1.1). There are basically three known methods to derive Gaussian bounds from on-diagonal bounds (1.2): Davies’s perturbation method (see [18, 25, 28]), the integrated maximum principle (see [34–36]) and finite propagation speed for the wave equation (see [53, 55]).

The main aim of the present paper is to introduce a new method for deducing Gaussian bounds from diagonal bounds (1.2), which relies mainly on the Phragmén–Lindelöf theorem. Our approach is closely related to the main idea behind complex interpolation, and it shows that

surprisingly the Gaussian bounds and the complex interpolation results are of similar nature. This allows us to look at the off-diagonal Gaussian bounds from a new perspective. The use of Phragmén–Lindelöf theorems for heat kernel estimates was introduced to our knowledge in [27], see in particular Lemma 9; see also [25, Theorem 3.4.8, p. 103]. In [27], Davies used Gaussian bounds for real time and the Phragmén–Lindelöf technique to obtain complex time estimates for the heat kernel, that is, estimates for $p_z(x, y)$ for all $z \in \mathbb{C}_+$, where $\mathbb{C}_+$ is the complex half-plane $\text{Re } z > 0$. Roughly speaking, in our approach, we reverse the order of Davies’s idea and we use the Phragmén–Lindelöf technique to obtain both real and complex time Gaussian bounds. Our method yields more precise complex time Gaussian bounds than in [25, Theorem 3.4.8, p. 103; 27].

We express the assumptions of our results in terms of the so-called Davies–Gaffney estimates. To our knowledge, these estimates were formulated for the first time in [26], but according to Davies himself the idea stems from [32]. Davies–Gaffney estimates hold for essentially all self-adjoint, elliptic or subelliptic second-order differential operators including Laplace–Beltrami operators on complete Riemannian manifolds, Schrödinger operators with real-valued potentials and electromagnetic fields, and Hodge Laplace operators acting on differential forms (see Theorem 3.3 and Section 4.3 below). A discrete time version of the Davies–Gaffney estimate was discussed in [24]; however, it is not clear how to extend the methods of the present work to the discrete time case, in order to replace the use of the rather technical discrete integrated maximum principle as in [24]. Davies–Gaffney estimates are also easy to obtain. For non-negative self-adjoint operators, they are equivalent with the finite-speed propagation property for the corresponding wave equation (see [55] and Section 3.2 below). We discuss this equivalence here as a simple but illuminating application of the Phragmén–Lindelöf technique.

Our approach allows us to obtain far-reaching generalizations of the results obtained in [18,25,28,34–36,53,55]. In the present paper, we do not have to assume anything about the nature of the infinitesimal generator of the semigroup under consideration; in particular, the generating operator does not have to be a second-order differential operator, and the semigroup does not have to be Markov. Our method works also for operators acting on differential forms and more generally on vector bundles (it is worth to recall at this point that there is a connection between estimates of the heat kernel on 1-forms and the $L^p$ boundedness of the Riesz transform for $p > 2$; see, for example, [22, 23, 55]). Actually, instead of considering the analytic semigroup $\{\exp(-zL) : z \in \mathbb{C}_+\}$ generated by some non-negative self-adjoint operator $L$, we study any uniformly bounded analytic family of operators $\{\Psi(z) : z \in \mathbb{C}_+\}$. We do not have to assume that $\Psi$ has the semigroup property nor that $\Psi(z)$ is a linear operator, as long as $\{\Psi(z) : z \in \mathbb{C}_+\}$ satisfies the Davies–Gaffney estimate (see (3.2) below). For example, we can study the estimates for the gradient of the heat kernel in the same way as the estimates for the heat kernel itself. We are also able to consider the family given by the formula $\Psi(z) = \exp(-zL) - \exp(-zL^0)$, where $L$, $L^0$ are different generators of analytic semigroups. For example, one can consider the situation where $L$ is an operator with periodic coefficients in divergence form and $L^0$ is its homogenization, to obtain Gaussian estimates for the difference of the corresponding heat kernels $|p_t(x, y) - p^0_t(x, y)|$.

Next, our methods have various applications in the theory of $L^p$ to $L^q$ Gaussian estimates, developed by Blunck and Kunstmann in [9–13]; see also [5, 46]. Blunck and Kunstmann call such estimates generalized Gaussian estimates. They use generalized Gaussian estimates to study $L^p$ spectral multipliers for operators without heat kernels. Our approach provides a strong tool to verify the generalized Gaussian estimates for a large class of operators. It is natural here to consider not only $L^p$ spaces but also other functional spaces. This leads to another generalization of Gaussian estimates (see Section 4.7 below).

Before we introduce all technical details needed to state our main results, we would like to discuss Theorems 1.1 and 1.2 below, which are only specific consequences of these results but provide a good non-technical illustration of our approach. In [25, Theorem 3.4.8, p. 103]
Davies showed that the Gaussian estimate for the heat kernel extends to complex values of time. The surprisingly simple proof of Theorem 1.1 yields a more precise version of [25, Theorem 3.4.8, p. 103], and at the same time it provides an alternative proof of real time off-diagonal Gaussian bounds obtained in [18, 25, 28]. Recall that the heat semigroup $\exp(-t\Delta)$ generated by the (non-negative) Laplace–Beltrami operator $\Delta$ on a complete Riemannian manifold $M$ is self-adjoint on $L^2(M)$ with a smooth positive kernel $p_t(x, y), t > 0, x, y \in M$, called the heat kernel on $M$; it extends to a complex time semigroup $\exp(-z\Delta), z \in \mathbb{C}^+, x, y \in M$. Denote by $d$ the geodesic distance on $M$.

**Theorem 1.1.** Let $p_z, z \in \mathbb{C}^+, be the heat kernel on a complete Riemannian manifold $M$. Suppose that

$$p_t(x, x) \leq K t^{-D/2}, \quad \forall t > 0, x \in M, \quad (1.3)$$

for some $K$ and $D > 0$. Then

$$|p_z(x, y)| \leq eK(\text{Re } z)^{-D/2} \left(1 + \text{Re } \frac{d^2(x, y)}{4z}\right)^{D/2} \exp\left(-\text{Re } \frac{d^2(x, y)}{4z}\right) \quad (1.4)$$

for all $z \in \mathbb{C}^+, x, y \in M$.

For $z = t \in \mathbb{R}^+$, estimates (1.4) can still be improved. It is possible to prove that

$$0 \leq p_t(x, y) \leq Ct^{-D/2} \left(1 + \frac{d^2(x, y)}{4t}\right)^{(D-1)/2} \exp\left(-\frac{d^2(x, y)}{4t}\right) \quad (1.5)$$

(see [53]). Moreover, it is known that the additional term $\left(1 + \frac{d^2(x, y)}{4t}\right)^{(D-1)/2}$ cannot be removed in general from (1.5). See [49] for a counterexample. However, using the Phragmén–Lindelöf technique we obtain the following variation of Theorem 1.1.

**Theorem 1.2.** Let $p_z, z \in \mathbb{C}^+, be the heat kernel on a complete Riemannian manifold $M$. Suppose that

$$|p_z(x, y)| \leq K|z|^{-D/2}, \quad \forall z \in \mathbb{C}^+, x, y \in M, \quad (1.6)$$

for some $K$ and $D > 0$. Then

$$|p_z(x, y)| \leq eK|z|^{-D/2} \exp\left(-\text{Re } \frac{d^2(x, y)}{4z}\right)$$

for all $z \in \mathbb{C}^+, x, y \in M$.

Theorems 1.1 and 1.2 are straightforward consequences of Theorems 4.2 and 4.3 below, and of the well-known fact that the Laplace–Beltrami operator on complete Riemannian manifolds satisfies Davies–Gaffney estimate; see the remark after Theorem 3.3 below or [26, 36].

Theorem 1.2 shows that one can remove the additional factor $\left(1 + \frac{d^2(x, y)}{4t}\right)^{(D-1)/2}$ in (1.5) if estimates (1.3) can be replaced by the stronger ones (1.6). This is an example of a result which we can obtain using the Phragmén–Lindelöf technique and which does not seem to follow from the techniques developed in [18, 25, 28, 34–36, 53, 55].

A reader who wants to have a quick overview of the method of proof of, say, Theorem 1.1 should look directly at Proposition 2.2, Theorem 3.3 and the beginning of Section 4.
2. Theorems of Phragmén–Lindelöf type

Let us start with stating the Phragmén–Lindelöf theorem for sectors.

**Theorem 2.1.** Let $S$ be the open region in $\mathbb{C}$ bounded by two rays meeting at an angle $\pi/\alpha$, for some $\alpha > 1/2$. Suppose that $F$ is analytic on $S$, continuous on $\overline{S}$ and satisfies $|F(z)| \leq C \exp(c|z|^\beta)$ for some $\beta \in [0, \alpha)$ and for all $z \in S$. Then the condition $|F(z)| \leq B$ on the two bounding rays implies that $|F(z)| \leq B$ for all $z \in S$.

For the proof see [48, Theorem 7.5, p. 214, vol. II] or [56, Lemma 4.2, p. 108]. Propositions 2.2–2.4 are simple consequences of Theorem 2.1.

**Proposition 2.2.** Suppose that $F$ is an analytic function on $\mathbb{C}_+$. Assume that, for given numbers $A, B, \gamma > 0$, we have

$$|F(z)| \leq B \quad \forall z \in \mathbb{C}_+, \tag{2.1}$$

and

$$|F(t)| \leq Ae^{at}e^{-\gamma/t}, \quad \forall t \in \mathbb{R}_+. \tag{2.2}$$

Then

$$|F(z)| \leq B \exp\left(-\Re \frac{\gamma}{z}\right), \quad \forall z \in \mathbb{C}_+. \tag{2.3}$$

**Proof.** Consider the function

$$u(\zeta) = F\left(\frac{\gamma}{\zeta}\right), \tag{2.4}$$

which is also defined on $\mathbb{C}_+$. By (2.1),

$$|u(\zeta)e^{\zeta}| \leq B \exp|\zeta| \quad \forall \zeta \in \mathbb{C}_+.$$ 

Again by (2.1) we have, for any $\varepsilon > 0$,

$$\sup_{\Re \zeta = \varepsilon} |u(\zeta)e^{\zeta}| \leq Be^\varepsilon. \tag{2.5}$$

By (2.2),

$$\sup_{\zeta \in [\varepsilon, \infty)} |u(\zeta)e^{\zeta}| \leq Ae^{a\gamma/\varepsilon}. \tag{2.6}$$

Hence, by the Phragmén–Lindelöf theorem with angle $\pi/2$ and $\beta = 1$, applied to

$$S^+ = \{z \in \mathbb{C} : \Re z > \varepsilon \text{ and } \Im z > 0\}$$

and

$$S^- = \{z \in \mathbb{C} : \Re z > \varepsilon \text{ and } \Im z < 0\},$$

one obtains

$$\sup_{\Re \zeta \geq \varepsilon} |u(\zeta)e^{\zeta}| \leq \max\{Ae^{a\gamma/\varepsilon}, Be^\varepsilon\} \quad \forall \varepsilon > 0.$$ 

Now by the Phragmén–Lindelöf theorem with angle $\pi$ and $\beta = 0$,

$$\sup_{\Re \zeta \geq \varepsilon} |u(\zeta)e^{\zeta}| \leq Be^\varepsilon \quad \forall \varepsilon > 0. \tag{2.7}$$
Letting $\varepsilon \to 0$ we obtain
\[ \sup_{\text{Re} \zeta > 0} |u(\zeta) e^\zeta| \leq B. \]
This proves (2.3) by substituting $\zeta = \gamma/z$.

Note that the estimate (2.3) does not depend on constants $A, a$ in (2.2). This simple observation is the heart of the matter in the present paper.

The above proposition will be used to prove the equivalence between the finite speed propagation property for the solution of the wave equation and Davies–Gaffney estimate (see §3.2 below). However, in order to study the Gaussian bounds for heat kernels, we need a more sophisticated version of Proposition 2.2.

Given $\gamma > 0$, denote by $C_\gamma$ the closed disk in $\mathbb{C}_+$ centered on the real axis, tangent to the imaginary axis, with radius $\gamma/2$, that is, the region
\[ C_\gamma = \{ z \in \mathbb{C} \setminus \{0\} : \text{Re} \frac{\gamma}{z} \geq 1 \} = \{ z \in \mathbb{C} : |z - \frac{\gamma}{2}| \leq \frac{\gamma}{2} \} \setminus \{0\}. \]

**Proposition 2.3.** Let $F$ be an analytic function on $\mathbb{C}_+$. Assume that, for given numbers $A, B, \gamma, \nu > 0$,
\[ |F(z)| \leq A \] (2.8)
for all $z \in \mathbb{C}_+$;
\[ |F(t)| \leq A e^{-\gamma/t} \] (2.9)
for all $t \in \mathbb{R}_+$ such that $t \leq \gamma$;
\[ |F(z)| \leq B \left( \frac{\text{Re} z}{4\gamma} \right)^{-\nu/2} \] (2.10)
for all $z \in C_\gamma$. Then
\[ |F(z)| \leq eB \left( \frac{2\gamma}{|z|} \right)^\nu \exp \left( -\text{Re} \frac{\gamma}{z} \right) \] (2.11)
for all $z \in C_\gamma$.

**Proof.** Consider again the function $u$ defined by (2.4). It satisfies conditions (2.5) and (2.6) with $B = A$, $a = 0$ and $\varepsilon = 1$. Hence by (2.7)
\[ \sup_{\text{Re} \zeta \geq 1} |u(\zeta) e^\zeta| \leq eA. \] (2.12)
Consider now the function $v$ defined on $\mathbb{C}_+$ by the formula
\[ v(\zeta) = (2\zeta)^{-\nu} u(\zeta) e^\zeta. \]
Note that $|v(\zeta)| \leq 2^{-\nu} |u(\zeta) e^\zeta|$ for $\text{Re} \zeta \geq 1$, and so by (2.12) $v$ is bounded on the set $\text{Re} \zeta \geq 1$.

Now, by the Phragmén–Lindelöf theorem with angle $\pi$ and $\beta = 0$,
\[ \sup_{\text{Re} \zeta \geq 1} |v(\zeta)| = \sup_{\text{Re} \zeta = 1} |v(\zeta)|. \]
Let $\zeta = 1 + is$. By (2.10),
\[
\sup_{\text{Re } \zeta = 1} |v(\zeta)| = \sup_{\text{Re } \zeta = 1} \left| (2\zeta)^{-\nu} F \left( \frac{\gamma}{\zeta} \right) e^\xi \right|
\leq \sup_{\text{Re } \zeta = 1} eB |2\zeta|^{-\nu} \left( \text{Re} \frac{1}{4\zeta} \right)^{-\nu/2}
\leq eB \sup_{s \in \mathbb{R}} (1 + s^2)^{-\nu/2} \left( \frac{1}{1 + s^2} \right)^{-\nu/2} = eB.
\]
Hence
\[
\sup_{\text{Re } \zeta \geq 1} |v(\zeta)| \leq eB.
\tag{2.13}
\]
Now we put $\zeta = \gamma/z$ in (2.13) and we obtain
\[
\left| \frac{2\gamma}{z} \right|^{-\nu} \left| F(z) \right| \exp \left( \frac{\gamma}{z} \right) \leq eB.
\]
This proves (2.11) for all $z \in \mathcal{C}_\gamma$. □

Finally let us discuss one more version of Proposition 2.3. We need this modified version to prove Theorem 1.2. The main difference between Propositions 2.3 and 2.4 is that we multiply the function $F$ by an analytic function $e^g$ satisfying a growth condition.

**Proposition 2.4.** Let $g$ and $F$ be analytic functions on $\mathbb{C}_+$. Assume that, for given numbers $C, c, \gamma > 0$ and $0 \leq \beta < 1$,
\[
|\exp g(z)| \leq C e^{c|z|^{-\beta}}
\tag{2.14}
\]
for all $z \in \mathcal{C}_\gamma$.

Next assume that $F$ satisfies conditions (2.8) and (2.9) and that
\[
|F(z)| \leq B \left( \frac{\text{Re } z}{4\gamma} \right)^{-\nu/2} \exp(-\text{Re } g(z))
\tag{2.15}
\]
for some $\nu > 0$ and all $z \in \mathcal{C}_\gamma$. Then
\[
|F(z)| \leq eB \left( \frac{2\gamma}{|z|} \right)^\nu \exp \left( -\text{Re } g(z) - \frac{\gamma}{z} \right)
\]
for all $z \in \mathcal{C}_\gamma$.

**Proof.** Define functions $u_1$ and $v_1$ on $\mathbb{C}_+$ by the formulae
\[
v_1(\zeta) = (2\zeta)^{-\nu} u_1(\zeta) e^\xi = (2\zeta)^{-\nu} u(\zeta) \exp \left( g \left( \frac{\gamma}{\zeta} \right) \right) e^\xi = (2\zeta)^{-\nu} F \left( \frac{\gamma}{\zeta} \right) \exp \left( g \left( \frac{\gamma}{\zeta} \right) \right) e^\xi.
\]
By (2.12) and (2.14),
\[
|v_1(\zeta)| \leq 2^{-\nu} |u_1(\zeta)e^\xi| = 2^{-\nu} |u(\zeta)e^\xi| \left| \exp \left( g \left( \frac{\gamma}{\zeta} \right) \right) \right| \leq 2^{-\nu} eAC e^{c\gamma - \beta |z|^{\beta}}
\]
if $\text{Re } \zeta \geq 1$. Now by the Phragmén–Lindelöf theorem with angle $\pi$,
\[
\sup_{\text{Re } \zeta \geq 1} |v_1(\zeta)| = \sup_{\text{Re } \zeta = 1} |v_1(\zeta)|.
\]
By \((2.15)\),

\[
\sup_{\Re\zeta=1} |v_1(\zeta)| \leq \sup_{\Re\zeta=1} eB|2\zeta|^{-\nu} \left( \Re \frac{1}{4\zeta} \right)^{-\nu/2},
\]

and the rest of the proof is as in Proposition 2.3.

3. Davies–Gaffney estimates

Let \((M, d, \mu)\) be a metric measure space; that is, \(\mu\) is a Borel measure with respect to the topology defined by the metric \(d\). Next let \(B(x, r) = \{ y \in M, d(x, y) < r \}\) be the open ball with center \(x \in M\) and radius \(r > 0\). For \(1 \leq p \leq +\infty\), we denote the norm of a function \(f \in L^p(M, d\mu)\) by \(\|f\|_p\), by \(\langle \cdot, \cdot \rangle\) the scalar product in \(L^2(M, d\mu)\), and if \(T\) is a bounded linear operator from \(L^p(M, d\mu)\) to \(L^q(M, d\mu)\), where \(1 \leq p, q \leq +\infty\), then we write \(\|T\|_{p \to q}\) for the operator norm of \(T\).

Suppose that, for every \(z \in \mathbb{C}_+\), \(\Psi(z)\) is a bounded linear operator acting on \(L^2(M, d\mu)\) and that \(\Psi(z), z \in \mathbb{C}_+\), is an analytic family of operators, in the sense that \(z \to \langle \Psi(z)g, f \rangle\) is analytic on \(\mathbb{C}_+\) for any \(f, g \in L^2(M, d\mu)\).

Assume in addition that

\[
\|\Psi(z)\|_{2 \to 2} \leq 1 \quad \forall z \in \mathbb{C}_+. \tag{3.1}
\]

For \(U_1, U_2 \subset M\) open subsets of \(M\), let \(d(U_1, U_2) = \inf_{x \in U_1, y \in U_2} d(x, y)\). We say that the family \(\{\Psi(z) : z \in \mathbb{C}_+\}\) satisfies the Davies–Gaffney estimate if

\[
|\langle \Psi(t)f_1, f_2 \rangle| \leq \exp\left( -\frac{r^2}{4t} \right) \|f_1\|_2 \|f_2\|_2 \tag{3.2}
\]

for all \(t > 0, U_i \subset M, f_i \in L^2(U_i, d\mu), i = 1, 2\) and \(r = d(U_1, U_2)\). We only assume that \(3.2\) holds for positive real \(t\).

A slightly different form of the Davies–Gaffney estimate is mostly considered in the literature (see, for instance, [26] or [36]): in our notation, it reads

\[
|\langle \Psi(t)\chi_{U_1}, \chi_{U_2} \rangle| \leq \exp\left( -\frac{r^2}{4t} \right) \sqrt{\mu(U_1)\mu(U_2)}, \tag{3.3}
\]

where \(\chi_U\) denotes the characteristic function of the set \(U\). Of course, \(3.3\) follows from \(3.2\) by taking \(f_1 = \chi_{U_1}\) and \(f_2 = \chi_{U_2}\). Conversely, assume \(3.3\) and let \(f_i = \sum_j c^i_j \chi_{A^i_j}\), where \(A^i_j \subset U_i\). Then

\[
\langle \Psi(t)f_1, f_2 \rangle \leq \sum_j \sum_{\ell} |c^1_j c^2_\ell|^2 (\mu(A^1_j)\mu(A^2_\ell))^{1/2} \exp\left( -\frac{d^2(A^1_j, A^2_\ell)}{4t} \right) \\
\leq \sum_j \sum_{\ell} |c^1_j c^2_\ell|^2 (\mu(A^1_j)\mu(A^2_\ell))^{1/2} \exp\left( -\frac{d^2(U_1, U_2)}{4t} \right). \tag{3.4}
\]

By \(3.1\), \(\langle \Psi(z)f_1, f_2 \rangle \leq \|f_1\|_2\|f_2\|_2\). Proposition 2.2 then yields \(3.2\) for such \(f_1, f_2\), and one concludes by density.

One may wonder what is the justification of the constant 4 in \(3.2\); we shall see in Theorem 3.4 below that in the case where \(\Psi(z)\) is a semigroup \(e^{-zL}\), 4 is the good normalisation between the operator \(L\) and the distance \(d\), namely it translates the fact that the associated wave equation has propagation speed 1.
The other constants in (3.1) and (3.2) have been normalized to 1 for simplicity; anyway then can be absorbed by multiplying accordingly the family $\Psi(z)$.

Examples. Semigroups of operators generated by non-negative self-adjoint operators always satisfy (3.1), and among them many examples of interest satisfy (3.2). Recall that, if $L$ is a non-negative self-adjoint operator on $L^2(M,d\mu)$, then one can construct the spectral decomposition $E_L(\lambda)$ of the operator $L$. For any bounded Borel function $m : [0,\infty) \to \mathbb{C}$, one then defines the operator $m(L) : L^2(M,d\mu) \to L^2(M,d\mu)$ by the formula

$$m(L) = \int_0^\infty m(\lambda) \, dE_L(\lambda).$$

Now, for $z \in \mathbb{C}_+$ and $m_z(\lambda) = \exp(-z\lambda)$, one sets $m_z(L) = \exp(-zL)$, $z \in \mathbb{C}_+$. By spectral theory the family $\Psi(z) = \{\exp(-zL) : z \in \mathbb{C}_+\}$, also called semigroup of operators generated by $L$, satisfies condition (3.1).

As we already said, condition (3.2) holds for all kinds of self-adjoint, elliptic, second-order-like operators. Condition (3.2) is well-known to hold for Laplace–Beltrami operators on all complete Riemannian manifolds. More precisely, condition (3.3) is proved for such operators in [26, 36]. See also the remark after Theorem 3.3. In the more general setting of Laplace type operators acting on vector bundles, condition (3.2) is proved in [55]. Another important class of semigroups satisfying condition (3.2) are semigroups generated by Schrödinger operators with real potential and magnetic field (see, for example, [54], as well as Theorem 3.3 and Section 4.3 below).

Note that self-adjointness and non-negativity of $L$ are a way to ensure that $\exp(-zL)$ is defined for $z \in \mathbb{C}_+$, and (3.1), but these conditions may hold for non-self-adjoint $L$, and they are sufficient by themselves to run the rest of our theory.

Condition (3.2) also hold in the setting of local Dirichlet forms (see, for example, [39, 58, Theorem 2.8; 57]). In this case the metric measure spaces under consideration are possibly not equipped with any differential structure. However, the semigroups associated with these Dirichlet forms do satisfy in general Davies–Gaffney estimates with respect to an intrinsic distance.

In the sequel, if $(M,d,\mu)$ is a metric measure space and $L$ a non-negative self-adjoint operator on $L^2(M,d\mu)$, then we shall say abusively that $(M,d,\mu,L)$ satisfies the Davies–Gaffney estimate if (3.2) holds with $\Psi(t) = e^{-tL}$.

3.1. Self-improving properties of Davies–Gaffney estimates

It is convenient to establish two simple lemmas concerning Davies–Gaffney estimates before discussing our main results. First we observe that given (3.1) it is enough to test (3.2) on balls only. Then we observe that any additional multiplicative constant or even additional exponential factor in (3.2) can be replaced by the constant in (3.1).

**Lemma 3.1.** Suppose that $(M,d,\mu)$ is a separable metric space and that the analytic family $\{\Psi(z) : z \in \mathbb{C}_+\}$ of bounded operators on $L^2(M,d\mu)$ satisfies condition (3.1), and condition (3.2) restricted to all balls $U_i = B(x_i,r_i), i = 1,2$, for all $x_1, x_2 \in M, r_1, r_2 > 0$. Then it satisfies the condition (3.2) for all open subsets $U_1, U_2$.

**Proof.** Let $U_1$ and $U_2$ be arbitrary open subsets of $M$; set $r = d(U_1,U_2)$. Let $f = \sum_{i=1}^k f_i$, where for all $1 \leq i \leq k$, $f_i \in L^2(B(x_i,r_i),d\mu)$, $B(x_i,r_i) \subset U_1$, and $f_{i_1}(x) f_{i_2}(x) = 0$ for all $x \in M, 1 \leq i_1 < i_2 \leq k$. Similarly let $g = \sum_{j=1}^\ell g_j$, where $g_j \in L^2(B(y_j,s_j),d\mu)$, $B(y_j,s_j) \subset U_2$ for all $1 \leq j \leq \ell$, and $g_{j_1}(x) g_{j_2}(x) = 0$ for all $x \in M, 1 \leq j_1 < j_2 \leq \ell$. Note that
After, if condition (3.2) holds for balls then

\[
|\langle \Psi(t)f, g \rangle| = \left| \langle \Psi(t) \sum_{i=1}^{k} f_i, \sum_{j=1}^{\ell} g_j \rangle \right|
\]

\[
= \sum_{i=1}^{k} \sum_{j=1}^{\ell} |\langle \Psi(t)f_i, g_j \rangle| 
\leq \sum_{i=1}^{k} \sum_{j=1}^{\ell} e^{-r^2/(4t)} \|f_i\|_2 \|g_j\|_2 
\leq e^{-r^2/(4t)} \left( \sum_{i=1}^{k} \|f_i\|_2 \right) \left( \sum_{j=1}^{\ell} \|g_j\|_2 \right) 
\leq e^{-r^2/(4t)} \sqrt{k\ell} \left( \sum_{i=1}^{k} \|f_i\|_2^2 \right)^{1/2} \left( \sum_{j=1}^{\ell} \|g_j\|_2^2 \right)^{1/2} 
= e^{-r^2/(4t)} \sqrt{k\ell} \|f\|_2 \|g\|_2.
\]

Now we assume that (3.1) holds; so if we put \( F(z) = \langle \Psi(z)f, g \rangle \) then Proposition 2.2 shows that the term \( C_{kl} \) in the above inequality can be replaced by 1. This means that (3.2) holds for \( f \) and \( g \). Now to finish the proof of the lemma, it is enough to note that, since \( M \) is separable, the space of all possible finite linear combinations of functions \( f \) such that \( \text{supp } f \subset B(x, r) \subset U \) is dense in \( L^2(U, d\mu) \). Moreover, if \( f = \sum_{i=1}^{k} f_i \) and \( f_i \in L^2(B(x_i, r_i), d\mu) \) for all \( 1 \leq i \leq k \), then there exist functions \( \hat{f}_i \in L^2(B(x_i, r_i), d\mu) \) such that \( f = \sum_{i=1}^{k} \hat{f}_i \) and, in addition, for all \( 1 \leq i_1 < i_2 \leq k, \hat{f}_{i_1}(x) \hat{f}_{i_2}(x) = 0 \) for all \( x \in M \).

**Lemma 3.2.** Suppose that the family \( \{ \Psi(z) : z \in \mathbb{C}_+ \} \) satisfies condition (3.1). Assume in addition that, for some \( C \geq 1 \) and some \( a > 0 \),

\[
|\langle \Psi(t)f_1, f_2 \rangle| \leq Ce^{at} e^{-r^2/(4t)} \|f_1\|_2 \|f_2\|_2 \quad \forall t > 0,
\]

(3.4)

whenever \( f_i \in L^2(M, d\mu), \text{supp } f_i \subseteq B(x_i, r_i), i = 1, 2, \) and \( r = d(B(x_1, r_1), B(x_2, r_2)) \). Then the family \( \{ \Psi(z) : z \in \mathbb{C}_+ \} \) satisfies condition (3.2).

**Proof.** Lemma 3.2 is a straightforward consequence of Proposition 2.2 and Lemma 3.1.

Let us give an application of Lemma 3.2 by giving yet another example where Davies–Gaffney estimates hold, namely Schrödinger semigroups with real potential. Suppose that \( \Delta \) is the non-negative Laplace–Beltrami operator on a Riemannian manifold \( M \) with Riemannian measure \( \mu \) and geodesic distance \( d \), and consider the operator \( \Delta + \mathcal{V} \) acting on \( C_\infty^c(M) \), where \( \mathcal{V} \in L^1_{\text{loc}}(M, d\mu) \). If we assume that \( \Delta + \mathcal{V} \geq 0 \) then we can define the Friedrichs extension of \( \Delta + \mathcal{V} \), which with some abuse of notation we also denote by \( \Delta + \mathcal{V} \) (see, for example, \[25\], Theorem 1.2.8).

**Theorem 3.3.** Suppose that \( \Delta \) is the Laplace–Beltrami operator on a Riemannian manifold \( M \), that \( \mathcal{V} \in L^1_{\text{loc}}(M, d\mu) \) and that \( \Delta + \mathcal{V} \geq 0 \) as a quadratic form. Then the semigroup \( \{ \Psi(z) = \exp(-z(\Delta + \mathcal{V})) : z \in \mathbb{C}_+ \} \) satisfies condition (3.2).
Proof. We start our proof with the additional assumption $\mathcal{V} \geq 0$. For $f \in L^2(M, d\mu)$, $t > 0$, $x \in M$, we put $f_t(x) = f(t, x) = \exp(-t(\Delta + \mathcal{V})) f(x)$. Let $\kappa > 0$, and a function $\xi \in C^\infty(M)$, both to be chosen later, such that $|\nabla \xi| \leq \kappa$, where $\nabla$ is the Riemannian gradient on $M$. Next, as in [27, 36, 55], we consider the integral

$$E(t) = \int_M |f(t, x)|^2 e^{\xi(x)} d\mu(x).$$

Then

$$\frac{E'(t)}{2} = \Re \int_M \partial_t f(t, x) \overline{f(t, x)} e^{\xi(x)} d\mu(x) = \Re \int_M ((\Delta + \mathcal{V}) f_t) \overline{f_t} e^{\xi} d\mu$$

$$= -\Re \int_M (\nabla f_t \cdot \nabla (f_t e^{\xi}) + |f_t|^2 \mathcal{V} e^{\xi}) d\mu$$

$$= -\Re \int_M (|\nabla f_t|^2 + \nabla f_t \cdot f_t \nabla \xi + |f_t|^2 \mathcal{V}) e^{\xi} d\mu$$

$$\leq \int_M (-|\nabla f_t|^2 + |\nabla f_t||\nabla \xi||f_t|) e^{\xi} d\mu$$

$$\leq \frac{1}{4} \int_M |f_t|^2 |\nabla \xi|^2 e^{\xi} d\mu \leq \kappa^2 E(t)$$

(note that the non-negativity of $\mathcal{V}$ is used in the first inequality). Hence $E(t) \leq \exp(\kappa^2 t/2) E(0).

Consider now two disjoint open sets $U_1$ and $U_2$ in $M$. Choose $\xi = \kappa d(\cdot, U_1)$. One has $|\nabla \xi| \leq \kappa$, $\xi \equiv 0$ on $U_1$, and, for any $g \in L^2_{\text{loc}}(M, d\mu)$,

$$\int_{U_2} |g|^2 e^{\xi} d\mu \geq e^{\kappa r} \int_{U_2} |g|^2 d\mu,$$

where $r = d(U_1, U_2)$. Hence if $\text{supp } f \subseteq U_1$ then, taking $g = f_t$,

$$\int_{U_2} |f_t|^2 d\mu \leq e^{-\kappa r} E(t) \leq \exp \left( \frac{\kappa^2 t}{2} \right) E(0) = \exp \left( \frac{\kappa^2 t}{2} - \kappa r \right) \int_{U_1} |f|^2 d\mu.$$

Choosing finally $\kappa = r/t$ we obtain

$$\int_{U_2} |\Psi(t)f|^2 d\mu \leq \exp \left( -\frac{r^2}{2t} \right) \int_{U_1} |f|^2 d\mu,$$

that is, for all $f \in L^2(U_1, d\mu)$,

$$\sup_{g \in L^2(U_2, d\mu), \|g\|_2 = 1} |\langle \Psi(t)f, g \rangle|^2 = \int_{U_2} |\Psi(t)f|^2 d\mu \leq \exp \left( -\frac{r^2}{2t} \right) \|f\|_2^2,$$

which yields (3.2). Next, we consider a potential $\mathcal{V} \in L^1_{\text{loc}}(M)$ such that $\Delta + \mathcal{V} \geq 0$. We put $\mathcal{V}_a(x) = \max \{\mathcal{V}(x), -a\}$ and $L_a = \Delta + \mathcal{V}_a$. When $a$ goes to $\infty$, we find that $L_a$ converges to $L = \Delta + \mathcal{V}$ in the strong resolvent sense (see [41, Theorem VIII.3.3, p. 454] or [52, Theorem S.16, p. 373]). Hence by [52, Theorem VIII.20, p. 286] or by [41, Theorem VIII.3.11, p. 459 and Theorem IX.2.16, p. 504], we see that $\exp(-tL_a)f$ converges to $\exp(-tL)f = \exp(-t(\Delta + \mathcal{V}))f$ for any $f \in L^2(M)$. Therefore it is enough to prove (3.2) for $\exp(-tL_a)f$, with $a$ given in $\mathbb{R}$. Finally we note that $\mathcal{V}_a + a \geq 0$; thus it follows from the first part of the proof that

$$\exp(-t(\Delta + \mathcal{V}_a + a)) = e^{-at} \exp(-tL_a)$$

satisfies condition (3.2). However, this implies that the semigroup $\exp(-tL_a)$ satisfies condition (3.4), and Theorem 3.3 follows from Lemma 3.2. \qed

Remark. Note that the case $\mathcal{V} = 0$ is allowed in Theorem 3.3; in other words, it yields a proof of (3.2) for the Laplace–Beltrami operator on complete Riemannian manifolds.
3.2. Finite speed propagation for the wave equation and Davies–Gaffney estimate

As a next application of the Phragmén–Lindelöf technique developed in Section 2, we show that, for self-adjoint operators, Davies–Gaffney estimate are equivalent to finite speed propagation property for the corresponding wave equation. This equivalence was proved, along the same lines, in [55]. The underlying idea is so basic to the development of the technique in the present paper that we shall repeat this proof. One can use this equivalence to obtain a very simple proof of the finite speed propagation property for a broad class of self-adjoint operators (see [55]). We start with recalling the notion of finite speed propagation property for the wave equation.

In this section, \((M,d,\mu)\) is again a metric measure space. We say that a non-negative self-adjoint operator \(L\) satisfies the finite speed propagation property for solutions of the corresponding wave equation if

\[
\langle \cos(t\sqrt{L})f_1, f_2 \rangle = 0
\]

for all \(0 < t < r\), open sets \(U_i \subset M\), \(f_i \in L^2(U_i, d\mu)\), \(i = 1, 2\), where \(r = d(U_1, U_2)\).

If \(\cos(t\sqrt{L})\) is an integral operator with kernel \(K_t\), then (3.5) simply means that \(\text{supp} K_t \subseteq D_t\); that is, \(K_t(x_1, x_2) = 0\) for all \((x_1, x_2) \notin D_t\), where

\[
D_t = \{(x_1, x_2) \in M \times M : d(x_1, x_2) \leq t\}.
\]

**Theorem 3.4.** Let \(L\) be a self-adjoint non-negative operator acting on \(L^2(M, d\mu)\). Then the finite speed propagation property (3.5) and Davies–Gaffney estimate (3.2) are equivalent.

**Proof.** Assume the Davies–Gaffney estimate. Fix two open sets \(U_1, U_2 \subset M\). Let \(f_i \in L^2(U_i, d\mu)\) for \(i = 1, 2\). Define a function \(F : \mathbb{C}_+ \rightarrow \mathbb{C}\) by

\[
F(z) = \langle \exp(-zL)f_1, f_2 \rangle.
\]

Since \(\exp(-zL)\) is contractive on \(L^2(M, d\mu)\), it follows that \(F\) is a bounded analytic function on \(\mathbb{C}_+\) and it satisfies (2.1) with

\[
B = \|f_1\|_2\|f_2\|_2.
\]

By virtue of (3.2), the function \(F\) satisfies (2.2) with

\[
a = 0, \quad A = \|f_1\|_2\|f_2\|_2, \quad \gamma = \frac{r^2}{4} \quad \text{and} \quad r = d(U_1, U_2);
\]

thus, by Proposition 2.2,

\[
|F(z)| \leq \|f_1\|_2\|f_2\|_2 \exp \left(-t^2 \Re \frac{1}{4z} \right).
\]

Then write, for \(s > 0\), the well-known Hadamard transmutation formula

\[
\langle \exp(-sL)f_1, f_2 \rangle = \int_0^\infty \langle \cos(t\sqrt{L})f_1, f_2 \rangle \frac{e^{-t^2/(4s)}}{\sqrt{\pi s}} dt.
\]

By the change of variable \(t \to \sqrt{t}\) in integral (3.8) and changing \(s\) to \(1/(4s)\), we obtain

\[
s^{-1/2} \left\langle \exp \left(-\frac{L}{4s}\right)f_1, f_2 \right\rangle = \int_0^\infty (\pi t)^{-1/2} \left\langle \cos(\sqrt{t}\sqrt{L})f_1, f_2 \right\rangle e^{-st} dt,
\]

and by analytic continuation

\[
\zeta^{-1/2} \left\langle \exp \left(-\frac{L}{4\zeta}\right)f_1, f_2 \right\rangle = \int_0^\infty (\pi t)^{-1/2} \left\langle \cos(\sqrt{t}\sqrt{L})f_1, f_2 \right\rangle e^{-\zeta t} dt
\]
for \( \zeta \in \mathbb{C}_+ \). Consider the function \( u(\zeta) = \zeta^{-1/2} F(1/4\zeta) \). On the one hand, by (3.7),
\[
|u(\zeta)| \leq \|f_1\|_2 \|f_2\|_2 |\zeta|^{-1/2} \exp(-r^2 \text{Re} \zeta).
\]
On the other hand, by (3.9), \( u \) is the Fourier-Laplace transform of the function
\[
v(t) = (\pi t)^{-1/2} \left( \cos(\sqrt{t} L) f_1, f_2 \right).
\]

Thus, \( \langle \cos(\sqrt{t} L) f_1, f_2 \rangle = 0 \) for all \( 0 \leq t \leq r^2 \), and (3.5) is proved.
Conversely, if (3.5) holds, then by (3.8)
\[
|\langle \exp(-sL) f_1, f_2 \rangle| \leq \int_0^\infty \left| \langle \cos(t\sqrt{L}) f_1, f_2 \rangle \right| e^{-t^2/(4s)} dt
= \int_0^\infty \left| \langle \cos(t\sqrt{L}) f_1, f_2 \rangle \right| e^{-t^2/(4s)} dt
\leq \|f_1\|_2 \|f_2\|_2 \int_0^\infty e^{-t^2/(4s)} dt
\leq e^{-r^2/(4s)} \|f_1\|_2 \|f_2\|_2.
\]

**4. From on-diagonal bounds to Gaussian bounds**

In this section, \((M, d, \mu)\) is again a metric measure space. Let \( L \) be a non-negative self-adjoint operator acting on \( L^2(M, d\mu) \); recall that the semigroup of operators \( \Psi(z) = \exp(-zL), z \in \mathbb{C}_+ \), is contractive on \( L^2(M, d\mu) \), in other words it satisfies condition (3.1).

Our basic observation is the following: if \( p_\ast \) is the kernel associated with \( \exp(-zL) \), then the estimate
\[
p_t(x, x) \leq K t^{-D/2} \quad \forall t > 0
\]
can be reformulated as
\[
\|\exp(-tL)\|_{1 \to \infty} \leq K t^{-D/2} \quad \forall t > 0,
\]
which yields
\[
\|\exp(-zL)\|_{1 \to \infty} \leq K (\text{Re} z)^{-D/2} \quad \forall z \in \mathbb{C}_+;
\]
that is, in terms of a bilinear estimate,
\[
|\langle \exp(-zL) f_1, f_2 \rangle| \leq K (\text{Re} z)^{-D/2} \|f_1\|_1 \|f_2\|_1 \quad \forall z \in \mathbb{C}_+, \ f_1, f_2 \in L^1(M, d\mu).
\]

On the other hand, Davies–Gaffney estimate says that
\[
|\langle \exp(-tL) f_1, f_2 \rangle| \leq \exp \left( -\frac{t^2}{4t} \right) \|f_1\|_2 \|f_2\|_2
\]
for all \( t > 0 \), \( f_1, f_2 \in L^2(M, d\mu) \), supported respectively in \( U_1, U_2 \), with \( r = d(U_1, U_2) \). With these ingredients and the global \( L^2 \) bound on the complex half-plane
\[
|\langle \exp(-zL) f_1, f_2 \rangle| \leq \|f_1\|_2 \|f_2\|_2 \quad \forall z \in \mathbb{C}_+, \ f_1, f_2 \in L^2(M, d\mu),
\]
the suitable Phragmén–Lindelöf-type lemma yields
\[
|\langle \exp(-zL) f_1, f_2 \rangle| \leq eK (\text{Re} z)^{-D/2} \left( \text{Re} \frac{r^2}{4z} \right)^{D/2} \exp \left( -\text{Re} \frac{r^2}{4z} \right) \|f_1\|_1 \|f_2\|_1,
\]
for \( z \) in the relevant region of the half-plane and all \( f_1, f_2 \in L^1(M, d\mu) \), supported in \( U_1, U_2 \), with \( r = d(U_1, U_2) \). Taking for \( U_1, U_2 \) balls that shrink around \( x \) and \( y \), one obtains, for 
\[
\Re (d^2(x, y))/4z \]
large enough, the desired estimate
\[
|p_z(x, y)| \leq cK(\Re z)^{-D/2} \left( \frac{\Re d^2(x, y)}{4z} \right)^{D/2} \exp \left( -\Re \frac{d^2(x, y)}{4z} \right).
\]

Let us see this in more detail, and then in more general situations.

4.1. **Polynomial decay**

Assume that

\[
\| \exp(-tL) \|_{1 \to \infty} \leq Kt^{-D/2} \quad \forall t > 0.
\]

It follows that

\[
\| \exp(-zL) \|_{1 \to \infty} \leq K(\Re z)^{-D/2}, \quad \forall z \in \mathbb{C}_+.
\]

Indeed, for \( t > 0, s \in \mathbb{R}, \)
\[
\| \exp(-(t + is)L) \|_{1 \to \infty} \leq \| \exp(-tL/2) \|_{1 \to 2} \| \exp(-isL) \|_{2 \to 2} \| \exp(-tL/2) \|_{2 \to \infty}
\]
\[
= \| \exp(-tL/2) \|_{2 \to 2} \| \exp(-isL) \|_{2 \to 2}
\]
\[
= \| \exp(-tL) \|_{1 \to \infty} \| \exp(-isL) \|_{2 \to 2}
\]
\[
\leq K t^{-D/2},
\]

using the well-known equality \( \| T^*T \|_{1 \to \infty} = \| T \|_{1 \to 2}^2 \) and the fact that, \( L \) being self-adjoint, \( \exp(-isL) \) is contractive.

In particular, by [29, Theorem 6, p. 503], \( \exp(-zL) \) is an integral operator for all \( z \in \mathbb{C}_+. \)

This means that there exists a measurable kernel, which we denote by \( p_z(x, y) \), such that

\[
|\exp(-zL)f(x)| = \int_M p_z(x, y)f(y) \, d\mu(y) \quad \text{for a.e. } x \in M.
\]

Before we start discussing Gaussian bounds, let us state another straightforward consequence of [29, Theorem 6, p. 503], which we are going to use frequently in the sequel. A linear operator \( S \) is bounded from \( L^1(M, d\mu) \) to \( L^\infty(M, d\mu) \) if and only if it is an integral operator with kernel \( p(x, y) \) such that \( \text{ess sup}_{x \in M, y \in M} |p(x, y)| \) is finite, in which case

\[
\text{ess sup}_{x \in M, y \in M} |p(x, y)| = \| S \|_{1 \to \infty}.
\]

More precisely, we have the following claim.

**Claim 4.1.** Let \( U_1, U_2 \) be open subsets of \( M \). If \( p(x, y) \) is the kernel of a linear operator \( S : L^1(M, d\mu) \to L^\infty(M, d\mu) \), then

\[
\text{ess sup}_{x \in U_1, y \in U_2} |p(x, y)| = \sup \left\{ |\langle Sf_1, f_2 \rangle| : \| f_1 \|_{L^1(U_1, d\mu)} = \| f_2 \|_{L^1(U_2, d\mu)} = 1 \right\}.
\]

To complete the last step of the argument we sketched above, namely to pass from estimates on arbitrarily small balls to pointwise estimates, we need to assume space continuity of the kernel under consideration, which is the case in most concrete situations, but not in general.

We shall assume from now on that for every \( z \in \mathbb{C}_+ \) the kernel \( p_z \) is a continuous complex-valued function defined on \( M \times M \). Note that this is a non-trivial assumption. Davies told us about a folklore example of a decent Schrödinger operator on \( \mathbb{R} \) with on-diagonal values of the kernel that are null on a countable dense subset. On the other hand, it is not dispensable if one wants to give a meaning to \( p(x, x) \). For an interesting discussion about continuity properties of a general heat kernel, see [37].
As a consequence, we can replace the essential suprema by the suprema in the above expressions, and also record the following.

If \( p_t(x,y) \) is the kernel of \( \exp(-tL) \), then a well-known argument using the semigroup property and the fact that \( p_t(y,x) = p_t(x,y) \) (see the proof of (4.15) below) shows further that

\[
\| \exp(-tL) \|_{1 \to \infty} = \sup_{x,y \in M} |p_t(x,y)| = \sup_{x \in M} p_t(x,x). \tag{4.3}
\]

We can now state the general version of Theorem 1.1. An even more general version will be given in Corollary 4.5 below, at the expense of a slightly more complicated proof.

**Theorem 4.2.** Assume that \((M,d,\mu,L)\) satisfies the Davies–Gaffney estimate. If, for some \(K\) and \(D > 0\),

\[
p_t(x,x) \leq K \, t^{-D/2} \forall t > 0, \ x \in M, \tag{4.4}
\]

then

\[
|p_z(x,y)| \leq e K (\text{Re } z)^{-D/2} \left( 1 + \text{Re} \, \frac{d^2(x,y)}{4z} \right)^{D/2} \exp \left( -\text{Re} \, \frac{d^2(x,y)}{4z} \right) \tag{4.5}
\]

for all \( z \in \mathbb{C}_+, \ x, y \in M \).

**Proof.** Fix \( x, y \in M \), and for \( d(x,y) > 2s > 0 \) define a bounded analytic function \( F : \mathbb{C}_+ \to \mathbb{C} \) as in (3.6) by the formula

\[
F(z) = \langle \exp(-zL)f_1, f_2 \rangle,
\]

where \( f_1 \in L^1(B(x,s),d\mu) \cap L^2(B(x,s),d\mu) \), \( f_2 \in L^1(B(y,s),d\mu) \cap L^2(B(y,s),d\mu) \) and \( \|f_1\|_1 = \|f_2\|_1 = 1 \). By virtue of Davies–Gaffney conditions (3.1) and (3.2), \( F \) satisfies (2.8) and (2.9) with

\[
\gamma = r^2/4, \text{ where } r = d(x,y) - 2s, \text{ and } A = \|f_1\|_2 \|f_2\|_2 < \infty.
\]

Assumption (4.4) yields, through (4.1) and (4.3),

\[
|F(z)| = |\langle \exp(-zL)f_1, f_2 \rangle| \leq K (\text{Re } z)^{-D/2} \forall z \in \mathbb{C}_+,
\]

such that \( F \) satisfies (2.10) with \( \nu = D \) and \( B = K r^{-D} \). By Proposition 2.3,

\[
|F(z)| = |\langle \exp(-zL)f_1, f_2 \rangle| \leq e K r^{-D} \left( \frac{r^2}{2|z|} \right)^D \exp \left( -\text{Re} \, \frac{r^2}{4z} \right)
\]

\[
= e K \left( \frac{r^2}{4|z|^2} \right)^{D/2} \exp \left( -\text{Re} \, \frac{r^2}{4z} \right)
\]

\[
= e K (\text{Re } z)^{-D/2} \left( \text{Re} \, \frac{r^2}{4z} \right)^{D/2} \exp \left( -\text{Re} \, \frac{r^2}{4z} \right)
\]

for all \( z \in \mathbb{C}_{r^2/4} \).

Hence by Claim 4.1

\[
|p_z(x,y)| \leq \sup_{z' \in B(x,s)} \sup_{y' \in B(y,s)} |p_z(x',y')| = \sup \{ |\langle \exp(-zL)f_1, f_2 \rangle| : \|f_1\|_{L^1(B(x,s),d\mu)} = \|f_2\|_{L^1(B(y,s),d\mu)} = 1 \}
\]

\[
\leq e K (\text{Re } z)^{-D/2} \left( \text{Re} \, \frac{r^2}{4z} \right)^{D/2} \exp \left( -\text{Re} \, \frac{r^2}{4z} \right)
\]

for all \( z \in \mathbb{C}_{r^2/4} \).
Letting $s$ go to 0 we obtain (4.5) for $\Re(d^2(x, y))/(4z) \geq 1$. Finally for $\Re(d^2(x, y))/(4z) < 1$, estimate (4.5) is a straightforward consequence of (4.4). Indeed, in that case the Gaussian correction term satisfies $\exp(-\Re(d^2(x, y))/(4z)) > e^{-1}$, and the estimate (4.5) follows from $|p_z(x, y)| \leq K(\Re z)^{-D/2}$, which in turn follows from (4.1).

Now for the general version of Theorem 1.2. Again, an even more general version will be given in Theorem 4.7 below.

**Theorem 4.3.** Assume that $(M, d, \mu, L)$ satisfies the Davies–Gaffney estimate. Next suppose that

$$|p_z(x, y)| \leq K|z|^{-D/2} \quad \forall z \in \mathbb{C}_+, \ x, y \in M,$$

for some $K$ and $D > 0$. Then

$$|p_z(x, y)| \leq eK|z|^{-D/2} \exp\left(-\Re \frac{d^2(x, y)}{4z}\right)$$

for all $z \in \mathbb{C}_+, \ x, y \in M$.

**Proof.** One starts as in the proof of Theorem 4.2. Then condition (4.6) yields

$$F(z) := ||(\exp(-zL)f_1, f_2)|| \leq K|z|^{-D/2}.$$

Choosing $g$ so that $|\exp(g(z))| = |z|^{D/2}$ and taking $B = K$, $\gamma = r^2/4$, $\beta = 0$, $\nu = 0$ in Proposition 2.4, one obtains

$$|(\exp(-zL)f_1, f_2)| \leq K|z|^{-D/2} \exp\left(-\Re \frac{r^2}{4z}\right)$$

and the rest of the proof is as before.

**Remark.** The fact that an on-diagonal estimate for the heat kernel implies an off-diagonal estimate is of course not new. See, for example, [25, Theorem 3.2.7, p. 89] for the real time estimate and [25, Theorem 3.4.8, p. 103] for the complex time estimate. Note however, that the results obtained in [25] are less precise than (4.5) because they involve $4 + \varepsilon$ instead of $4$ in the exponential factor. To our knowledge, the estimates (4.5) with $4$ as an exponential factor are new for complex time. On the other hand, for real time and diffusion semigroups, estimates (4.5) were obtained in [28] (see also [18]).

For $z = t \in \mathbb{R}_+$, the estimates (4.5) can still be improved. It is possible to prove that

$$|p_t(x, y)| \leq Ct^{-D/2} \left(1 + \frac{d^2(x, y)}{4t}\right)^{(D-1)/2} \exp\left(-\frac{d^2(x, y)}{4t}\right)$$

(see [53]), and this is sharp due to [49]. It is an interesting question why our results here (and results in [18, 28]) give weaker estimates with $D/2$ instead of $(D-1)/2$. It is so because in our proof we do not use the fact that the family of operators under consideration is a semigroup generated by a self-adjoint operator; for more on this, see the discussion in the remark at the end of Section 4.5.

Suppose now that the self-adjoint contractive semigroup $\exp(-tL)$ on $L^2(M, d\mu)$ is in addition uniformly bounded on $L^\infty(M, d\mu)$, which includes the case of the heat semigroup.
on a complete Riemannian manifold, since it is submarkovian. Suppose also that estimates (4.4) hold and that
\[ \| \exp(isL) \|_{1 \to \infty} \leq C|s|^{-D/2} \quad \forall s \in \mathbb{R} \setminus \{0\}. \] (4.8)
Then the semigroup \( \exp(-zL) \) satisfies condition (4.6), and hence the corresponding heat kernel satisfies estimates (4.7). Indeed, by (4.8), for all \( t > 0, s \in \mathbb{R} \),
\[ \| \exp(-(t + is)L) \|_{1 \to \infty} \leq \| \exp(-tL/2) \|_{\infty \to \infty} \| \exp(isL) \|_{1 \to \infty} \leq C|s|^{-D/2}. \]
Together with (4.1) this yields
\[ \| \exp(-(t + is)L) \|_{1 \to \infty} \leq C \min\{t^{-D/2}, |s|^{-D/2}\} \leq C'|t + is|^{-D/2} \]
for all \( t > 0, s \in \mathbb{R} \) (as a matter of fact, (4.6) is equivalent to the conjunction of (4.4) and (4.8)). This shows that Gaussian bounds without an additional polynomial correction factor are a necessary condition for (4.8) to hold. Let us observe that estimates (4.8) play an essential role in studying Strichartz–type estimates (see, for example, [42]).

4.2. The doubling case

Let \((M, d, \mu)\) be a metric measure space as above, and let \(p_z, z \in \mathbb{C}_+\), be a continuous heat kernel corresponding to a non-negative self-adjoint operator \(L\) on \(L^2(M, d\mu)\).

One says that \((M, d, \mu)\) satisfies the doubling property if there exists \(C > 0\) such that
\[ \mu(B(x, 2r)) \leq C\mu(B(x, r)) \quad \forall r > 0, \ x \in M. \] (4.9)
If this is the case, then there exist \(C, \delta > 0\) such that
\[ \frac{\mu(B(x, s))}{\mu(B(x, r))} \leq C \left( \frac{s}{r} \right)^\delta \quad \forall s \geq r > 0, \ x \in M. \] (4.10)

In such a situation, the most natural on-diagonal estimates for heat kernels are of the type
\[ p_t(x, x) \leq \frac{C}{\mu(B(x, \sqrt{t}))} \quad \forall t > 0, \ x \in M \]
(see, for instance, [36]).

We are going to consider the estimates of a similar form, but where the quantity \(\mu(B(x, \sqrt{t}))\) will be replaced by a function \(V\) of \(x\) and \(t\) that is not necessarily connected with the volume of balls.

We shall assume that \(V : M \times \mathbb{R}_+ \to \mathbb{R}_+\) is non-decreasing in the second variable, that is, \(V(x, s) \leq V(x, r)\) for all \(x \in M\) and all \(0 < s \leq r\), and that it satisfies the doubling condition
\[ \frac{V(x, s)}{V(x, r)} \leq K' \left( \frac{s}{r} \right)^\delta \] (4.11)
for all \(s \geq r > 0\) and all \(x \in M\), and some constants \(\delta \geq 0\) and \(K' \geq 1\). Finally we shall assume that \(V(x, t)\) is a continuous function of \(x\).

We shall then consider the on-diagonal estimate
\[ p_t(x, x)V(x, \sqrt{t}) \leq 1 \quad \forall x \in M, \ t > 0. \] (4.12)
One should compare the following result with [55, Theorem 4], which yields a slightly more precise estimate for real time.

**Theorem 4.4.** Assume that \((M, d, \mu, L)\) satisfies the Davies–Gaffney estimate. Next assume that the corresponding heat kernel \(p_z\) is continuous and satisfies the on-diagonal
estimate (4.12) with $V$ satisfying the doubling condition (4.11). Then

$$|p_z(x, y)| \leq \frac{e^{K'}}{\sqrt{V(x, d(x, y)/2)} \sqrt{V(y, d(x, y)/2)}} \left( \frac{d^2(x, y)}{4|z|} \right)^\delta \exp\left(-\text{Re} \frac{d^2(x, y)}{4z}\right) \quad (4.13)$$

for all $z \in \mathbb{C}_+, x, y \in M$ such that $\text{Re}(d^2(x, y))/(4z) \geq 1$. For all $z \in \mathbb{C}_+, x, y \in M$, and in particular if $\text{Re}(d^2(x, y))/(4z) < 1$, then one has

$$|p_z(x, y)| \leq \frac{1}{\sqrt{V(x, \text{Re} z)V(y, \sqrt{\text{Re} z})}}. \quad (4.14)$$

**Proof.** For all $z \in \mathbb{C}_+, x, y \in M$, one has

$$|p_z(x, y)| \leq \sqrt{p\text{Re}z(x, x)p\text{Re}z(y, y)}. \quad (4.15)$$

Indeed,

$$|p_z(x, y)| = \left| \int_M p_{z/2}(x, u)p_{z/2}(u, y) \mu(u) \right|$$

$$\leq \left( \int_M |p_{z/2}(x, u)|^2 \mu(u) \right)^{1/2} \left( \int_M |p_{z/2}(u, y)|^2 \mu(u) \right)^{1/2}$$

$$= \left( \int_M p_{z/2}(x, u)p_{z/2}(u, x) \mu(u) \right)^{1/2} \left( \int_M p_{z/2}(y, u)p_{z/2}(u, y) \mu(u) \right)^{1/2}$$

$$\leq \sqrt{p\text{Re}z(x, x)p\text{Re}z(y, y)}.$$

In the second equality above, we have used the fact that, since $L$ is self-adjoint, $p_z(x, y) = p_z(y, x)$. Together with (4.12), this yields (4.14).

For a function $W : M \to \mathbb{C}$, we denote by $m_W$ the operator of multiplication by $W$, that is,

$$\langle m_W f(x) \rangle = W(x)f(x),$$

and if $W : M \times \mathbb{R}_+ \to \mathbb{C}$ then for $r \in \mathbb{R}_+$, we set

$$\langle m_W(\cdot, r) f(x) \rangle = W(x, r)f(x).$$

Let us now set $W(x, r) = \sqrt{V(x, r)}$. Similarly as in the proof of Theorem 4.2, fix $x, y \in M$ and for $d(x, y) > 2s > 0$ set $r = d(x, y) - 2s$. Then define a bounded analytic function $F : \mathbb{C}_+ \to \mathbb{C}$ by the formula

$$F(z) = \langle \exp(-zL)m_{W(\cdot, r/2)} f_1, m_{W(\cdot, r/2)} f_2 \rangle, \quad (4.16)$$

where

$$f_1 \in L^1(B(x, s), d\mu) \cap L^2(B(x, s), V(\cdot, r/2) d\mu),$$

$$f_2 \in L^1(B(y, s), d\mu) \cap L^2(B(y, s), V(\cdot, r/2) d\mu),$$

and $\|f_1\|_1 = \|f_2\|_1 = 1$. By virtue of (3.2) and (3.1), $F$ satisfies (2.8) and (2.9) with

$$A = \|m_{W(\cdot, r/2)} f_1\|_2\|m_{W(\cdot, r/2)} f_2\|_2 < \infty \quad \text{and} \quad \gamma = r^2/4.$$

Note that, for $z \in \mathbb{C}_\gamma$,

$$\gamma \geq \left( \frac{\text{Re} \frac{1}{z}}{\text{Re} z} \right)^{-1} \geq \text{Re} z, \quad (4.17)$$
and hence \( r/2 \geq \sqrt{\Re z} \). Now by (4.11), (4.12) and (4.17)

\[
|F(z)| = \left| \int_M \int_M p_z(x', y') W \left( y', \frac{r}{2} \right) f_1(y') W \left( x', \frac{r}{2} \right) f_2(x') d\mu(y') d\mu(x') \right| \\
\leq \sup_{x', y' \in M} W \left( x', \frac{r}{2} \right) |p_z(x', y')| W \left( y', \frac{r}{2} \right) \\
\leq \sup_{x', y' \in M} \sqrt{V(x', \frac{r}{2}) V \left( y', \frac{r}{2} \right)} V(x, \sqrt{\Re z}) V(y, \sqrt{\Re z}) \leq K' \left( \frac{r}{2\sqrt{\Re z}} \right)^\delta = K' 2^{-\delta} \left( \frac{\Re z}{r^2} \right)^{-\delta/2}
\]

so that \( F \) satisfies (2.10) with \( B = K' 2^{-\delta} \) and \( \nu = \delta \). By Proposition 2.3,

\[
|F(z)| \leq eK' 2^{-\delta} \left( \frac{r^2}{2|z|} \right)^\delta \exp \left( -\frac{r^2}{4z} \right)
\]

for all \( z \in C_{r^2/4} \). Note that \( L^1(B(x, s), d\mu) \cap L^2(B(x, s), V(\cdot, r/2) d\mu) \) is dense in \( L^1(B(x, s), d\mu) \), so by Claim 4.1,

\[
V^{1/2} \left( x, \frac{r}{2} \right) |p_z(x, y)| V^{1/2} \left( y, \frac{r}{2} \right) \leq \sup_{x' \in B(x, s)} \sup_{y' \in B(y, s)} V^{1/2} \left( x', \frac{r}{2} \right) |p_z(x', y')| V^{1/2} \left( y', \frac{r}{2} \right) = \sup \left\{ |F(z)| : \|f_1\|_{L^1(B(x, s), d\mu)} = \|f_2\|_{L^1(B(y, s), d\mu)} = 1 \right\} \\
\leq eK' \left( \frac{r^2}{4|z|} \right)^\delta \exp \left( -\frac{r^2}{4z} \right)
\]

for all \( z \in C_{r^2/4} \). Letting \( s \to 0 \), we obtain the estimate (4.13) for \( z \in C_{d^2(x, y)/4} \).

Note that taking

\[
V(x, r) = K^{-1} r^D, \quad r > 0, \quad x \in M,
\]

one sees that Theorem 4.2 is a particular case of Theorem 4.4.

The estimate in the following corollary is less precise than the one in Theorem 4.4, but its algebraic form is convenient for calculations and it is enough for most applications; also, it can be compared with the case \( m = 2 \) of the estimates in [15, Proposition 4.1]. The improvement with respect to [15] is that the constant inside the exponential is optimal, at the expense of a necessary polynomial correction factor. To state the result, we put \( \theta = \arg z \) for all \( z \in \mathbb{C}_+ \), so that \( \cos \theta = \Re z/|z| \).

**Corollary 4.5.** Under the assumptions of Theorem 4.4,

\[
|p_z(x, y)| \leq \frac{eK' \left( 1 + \Re (d^2(x, y))/(4z) \right)^\delta}{\sqrt{V(x, \sqrt{|z|}/\cos \theta) V(y, \sqrt{|z|}/\cos \theta)}} \exp \left( -\Re \frac{d^2(x, y)}{4z} \right) \left( \frac{1}{\cos \theta} \right)^\delta (4.18)
\]

for all \( z \in \mathbb{C}_+ \), \( x, y \in M \).

**Proof.** Note that \( \Re z^{-1} = |z|^{-1} \cos \theta \), and hence

\[
\frac{d^2(x, y)}{4|z|} \cos \theta = \Re \frac{d^2(x, y)}{4z}, \quad z \in \mathbb{C}_+.
\]

Moreover, if \( z \in C_{d^2(x, y)/4} \), then

\[
\frac{d(x, y)}{2} \geq (\Re z^{-1})^{-1/2} = (|z|/\cos \theta)^{1/2}
\]
and hence
\[
V\left(x, \frac{d(x, y)}{2}\right) \geq V\left(x, \sqrt{\frac{|z|}{\cos \theta}}\right).
\]

Therefore
\[
\frac{1}{\sqrt{V(x, d(x, y)/2) V(y, d(x, y)/2)}} \left(\frac{d^2(x, y)}{4|z|}\right)^\delta \exp\left(-\frac{d^2(x, y)}{4z}\right) \leq \frac{1}{V\left(x, \sqrt{|z|/\cos \theta}\right) V\left(y, \sqrt{|z|/\cos \theta}\right)} \left(\frac{Re d^2(x, y)}{4z}\right)^\delta \exp\left(-\frac{Re d^2(x, y)}{4z}\right) \frac{1}{(\cos \theta)\delta}
\]
and for \( z \in C_{d^2(x, y)/4} \), estimate (4.18) follows from (4.13). Finally we note that by (4.11)
\[
V\left(x, \sqrt{\frac{|z|}{\cos \theta}}\right) \leq K' V\left(x, \sqrt{\frac{Re z}{\cos \theta}}\right) (\cos \theta)^{-\delta}
\]
so that, for \( z \not\in C_{d^2(x, y)/4} \), since \( \exp\left(-\frac{Re d^2(x, y)}{(4z)}\right) \geq e^{-1} \), it follows that (4.18) is a straightforward consequence of (4.14).

It is certainly an interesting feature of Corollary 4.5 that it yields estimates valid for time ranging in the whole right half-plane, and that it does not require \( V \) to be tied to the volume. Let us however observe the following particular case of our result, for real time and estimates involving the volume growth function. It also follows from [34, Proposition 5.2], but our proof is more direct, as it does not go through a Faber–Krahn-type inequality.

**Corollary 4.6.** Let \( p_t, t > 0 \), be the heat kernel on a complete Riemannian manifold \( M \), with Riemannian measure \( \mu \) and geodesic distance \( d \). Let \( V(x, r) \) denote \( \mu(B(x, r)) \), for \( r > 0 \), \( x \in M \). Assume that \( M \) satisfies the doubling property; more precisely, let \( K', \delta > 0 \) be such that (4.11) is satisfied. Suppose that
\[
p_t(x, x) \leq \frac{K}{V(x, \sqrt{t})} \quad \forall t > 0, x \in M,
\]
for some \( K > 0 \). Then
\[
p_t(x, y) \leq \frac{e^{K'K} (1 + (d^2(x, y)/4t))^{\delta}}{\sqrt{V(x, \sqrt{t}) V(y, \sqrt{t})}} \exp\left(-\frac{d^2(x, y)}{4t}\right)
\]
for all \( t > 0, x, y \in M \).

Let us now consider the case where the heat kernel satisfies upper and lower estimates of the type
\[
p_t(x, y) \simeq \frac{1}{\mu(B(x, t^{1/\beta}))} \exp\left(-\left(\frac{d^3(x, y)}{t}\right)^{1/(\beta-1)}\right) \quad \forall t > 0, x, y \in M.
\]
This may happen when \((M, d, \mu, L)\) is a fractal space, endowed with a natural metric, measure and Laplacian, for all values of \( \beta \) between 2 and \( \delta + 1 \), where \( \delta \) is the exponent in the doubling condition (4.11); see, for instance, [7]. In such situations, usually, \( \beta > 2 \). Let us now choose \( V(x, t) = \mu\left(B(x, t^{2/\beta})\right) \), which is obviously a doubling function. From (4.20), \( p_t \) satisfies (4.12),

GAUSSIAN BOUNDS VIA PHRAGMÉN–LINDELÖF THEOREM
but it cannot satisfy

\[ p_t(x,y) \leq \frac{C}{V(x,y/t)} \exp \left( -c \frac{d^2(x,y)}{t} \right) = \frac{C}{\mu(B(x,t^{1/\beta}))} \exp \left( -\frac{d^2(x,y)}{4t} \right), \]

since this is not compatible with the lower bound in (4.20). In view of Corollary 4.5, the only possible conclusion is that such a space \((M,d,\mu,L)\) does not satisfy Davies–Gaffney estimates nor, according to (3.4), the finite speed propagation property for the wave equation. We owe this remark to Alexander Teplyaev. There is no contradiction with the fact that local Dirichlet forms do give rise to Davies–Gaffney estimates with respect to an intrinsic distance: in the case of fractals, this distance degenerates; see the discussion in [39, Section 3.2]. For more considerations on wave-propagation speed on fractal-type manifolds, see [44].

Finally let us discuss one more version of pointwise Gaussian estimates. Here we do not need to consider any kind of doubling property. The following result has some similarity with [36, Corollary 5.5], in the sense that, in assumption (4.21) below, \(x,y\) do not range in the whole space \(M\), but only in two fixed regions \(U_1,U_2\). However, restricting our assumption to two fixed points \(x,y\) as in [36] seems to raise technical difficulties that we are not going to face here.

**Theorem 4.7.** Assume that \((M,d,\mu,L)\) satisfies the Davies–Gaffney estimate. Let \(U_1\) and \(U_2\) be open subsets of \(M\). Suppose that

\[ |p_z(x,y)| \leq \exp(-\text{Re} g(z)) \quad \forall z \in \mathbb{C}_+, \ x \in U_1, \ y \in U_2, \tag{4.21} \]

where \(g\) is analytic on \(\mathbb{C}_+\) and satisfies the growth condition (2.14) with \(\gamma = r^2/4\) and \(r = d(U_1, U_2)\). Then

\[ |p_z(x,y)| \leq \exp \left( 1 - \text{Re} g(z) - \text{Re} \frac{r^2}{4z} \right) \quad \forall z \in \mathbb{C}_+, \ x \in U_1, \ y \in U_2. \]

**Remark.**

- It may look surprising that the growth constraint on \(g\) depends on \(U_1, U_2\). This may be understood as follows: suppose a factor \(\exp(-\text{Re} r^2/(4z))\) is already present in estimate (4.21) (which corresponds to \(\beta = 1\), a situation hopefully forbidden by (2.14)); then one can certainly not multiply again the estimate by this factor!
- Theorem 4.7 is a generalization of Theorem 4.3, as one can see by taking \(g(z) = D/2 \log z - \log K\).
- In principle, one could use Theorem 4.7 to add a Gaussian factor to estimates of the form

\[ |p_z(x,y)| \leq \frac{1}{|V(x,y,z)|} \quad \forall z \in \mathbb{C}_+; \ x,y \in M, \]

where \(V\) is analytic in \(z\) with a certain uniformity in \(x,y\). We will not pursue this direction because of the lack of relevant examples.
- Note that our result allows to some extent rapid growth at zero. In particular, it might be interesting to investigate the connection with [8, Theorem 3.1].

**Proof.** Once again we follow the idea of the proof of Theorem 4.2 and define a bounded analytic function \(F : \mathbb{C}_+ \to \mathbb{C}\) by the formula

\[ F(z) = (\exp(-zL)f_1,f_2), \]

where \(f_i \in L^2(U_i,d\mu) \cap L^1(U_i,d\mu)\) and \(\|f_1\|_1 = \|f\|_2 = 1\). By virtue of (3.1) and (3.2), \(F\) satisfies (2.8) and (2.9) with

\[ r = d(U_1, U_2), \quad \gamma = r^2/4 \quad \text{and} \quad A = \|f_1\|_2 \|f_2\|_2 < \infty. \]
Next, by assumption (4.21),
\[ |F(z)| \leq \exp(-g(z)) \| f_1 \|_{L^1(U_1,d\mu)} \| f_2 \|_{L^1(U_2,d\mu)} = \exp(-\text{Re}\,g(z)) \quad \forall z \in \mathcal{C}_r^{2/4}, \]
that is, \( F \) satisfies (2.15) with \( B = 1, \nu = 0 \). By Proposition 2.4,
\[ |F(z)| \leq \exp \left( -\text{Re}\,g(z) + 1 - \frac{r^2}{4z} \right) \quad \forall z \in \mathcal{C}_r^{2/4}. \]
Finally by Claim 4.1
\[
\sup \sup_{x \in U_1, y \in U_2} |p_2(x, y)| = \sup \left\{ \exp(-zL) f_1, f_2 : \| f_1 \|_{L^1(U_1,d\mu)} = \| f_2 \|_{L^1(U_2,d\mu)} = 1 \right\} 
\leq \exp \left( -\text{Re}\,g(z) + 1 - \frac{r^2}{4z} \right)
\]
for all \( z \in \mathcal{C}_r^{2/4} \). The estimate for \( z \notin \mathcal{C}_r^{2/4} \) follows directly from (4.21).

4.3. Operators acting on vector bundles

Our approach not only works for operators acting on functions but can also be applied to operators acting on vector bundles. To discuss the vector bundle version of our results, we need some additional notation.

Let \((M, d, \mu)\) be a metric measure space and suppose that \( TM \) is a continuous vector bundle with base \( M \), fibers \( T_x M \simeq \mathbb{C}^n \) and with continuous (with respect to \( x \)) scalar product \( (\cdot, \cdot)_x \) on \( T_x M \). For \( f(x) \in T_x M \) we put \( |f(x)|_x^2 = (f(x), f(x))_x \). To simplify the notation, we will write \((\cdot, \cdot)_x \) and \( |\cdot|_x \) instead of \((\cdot, \cdot)_x \) and \(|\cdot|_x \). Now for sections \( f \) and \( g \) of \( TM \) we put
\[
\| f \|^p_{L^p(M, d\mu; TM)} = \int_M |f(x)|^p \, d\mu(x) \quad \text{and} \quad \langle f, g \rangle = \int_M (f(x), g(x)) \, d\mu(x).
\]

Now let us describe the notion of integral operators for vector bundles. For any point \((x, y) \in M^2 \) we consider the space \( T^*_y \otimes T_x \). The space \( T^*_y \otimes T_x \) is canonically isomorphic to \( \text{Hom}(T_y, T_x) \), the space of all linear homeomorphisms from \( T_y \) to \( T_x \). Denote again by \(|\cdot|_x \) the operator norm on \( T^*_y \otimes T_x \) with respect to the norms \(|\cdot|_y \) and \(|\cdot|_x \).

By \((T^* \otimes T)M^2 \) we denote the continuous bundle with base space equal to \( M^2 \) and with fiber over the point \((x, y) \) equal to \( T^*_y \otimes T_x \). If there is a section \( \bar{p} \) of \((T^* \otimes T)M^2 \) such that \( |\bar{p}| \) is a locally integrable function on \((M^2, \mu \times \mu)\) and \( \bar{S}f_1 \) is a section of \( TM \) such that
\[
\langle \bar{S}f_1, f_2 \rangle = \int_M (\bar{S}f_1(x), f_2(x)) \, d\mu(x) = \int_M (\bar{p}(x, y) f_1(y), f_2(x)) \, d\mu(y) \, d\mu(x)
\]
for all sections \( f_1 \) and \( f_2 \) in \( C_c(TM) \), then we say that \( \bar{S} \) is an integral operator on sections of \( TM \) with kernel \( \bar{p} \). As in the scalar case, \( \bar{S} \) is a bounded linear operator from \( L^1(M, d\mu; TM) \) to \( L^\infty(M, d\mu; TM) \) if and only if \( \bar{S} \) is an integral operator with kernel \( \bar{p} \) such that \( \text{esssup}_{x,y \in M} |\bar{p}(x, y)| \) is finite, and
\[ \text{esssup}_{x,y \in M} |\bar{p}(x, y)| = \| \bar{S} \|_{1 \to \infty}. \]

One also has the following vector-valued version of Claim 4.1.

CLAIM 4.8. Let \( U_1, U_2 \) be open subsets of \( M \). If \( \bar{p}(x, y) \) is the kernel of a linear operator \( \bar{S} : L^1(M, d\mu; TM) \to L^\infty(M, d\mu; TM) \), then
\[ \text{esssup}_{x \in U_1, y \in U_2} |\bar{p}(x, y)| = \sup \left\{ |\langle \bar{S}f_1, f_2 \rangle| : \|f_1\|_{L^1(U_1,d\mu;TM)} = \|f_2\|_{L^1(U_2,d\mu;TM)} = 1 \right\}. \]
Let us describe an example of Hodge-type operator which generates a semigroup satisfying conditions (3.1) and (3.2) and acts on vector bundles of $k$-forms on Riemannian manifolds. Suppose that $M$ is a complete $n$-dimensional Riemannian manifold and $\mu$ is an absolutely continuous measure with a smooth density not equal to zero at any point of $M$. By $\Lambda^kT^*M$, $k=0,\ldots,n$, we denote the bundle of $k$-forms on $M$. For fixed $\beta,\beta'\in L^2(\Lambda^1T^*M)$ and $\gamma\in L^2(\Lambda^kT^*M)$, we define the operator $\bar{L} = L_{\beta,\beta',\gamma}$ acting on $L^2(\Lambda^kT^*M)$ by the formula

$$\langle \bar{L}\omega, \omega \rangle = \int_M \left( |d_k\omega + \omega \wedge \beta|^2 + |d_{n-k} \ast \omega + \ast \omega \wedge \beta'|^2 + |\ast \omega \wedge \gamma|^2 \right) d\mu,$$

where $\omega$ is a smooth compactly supported $k$-form and $\ast$ is the Hodge star operator. With some abuse of notation we also denote by $\bar{L}$ its Friedrichs extension. Note that, for example, the Hodge–Laplace operator and Schrödinger operators with real potentials and electromagnetic fields can be defined by (4.22). The following theorem was proved in [55].

**Theorem 4.9.** The self-adjoint semigroup $\{\exp(-z\bar{L}) : z \in \mathbb{C}_+\}$ generated by the operator $\bar{L}$ defined by (4.22) acts on $L^2(\Lambda^kT^*M)$ and satisfies (3.1) and (3.2).

Theorems 4.2–4.4, 4.6 and Corollary 4.5 can be extended to the above setting of operators acting on vector bundles. For example, we can state Theorem 4.4 in this setting in the following way. Again, compare with [55, Corollary 9], which yields a slightly better estimate for real time and the Hodge–Laplace operator (and more generally operators defined by (4.22)) but does not treat complex time. In what follows, $\text{Tr}$ denotes the trace of an endomorphism on a finite dimensional linear space.

**Theorem 4.10.** Let $(M, d, \mu)$ be a metric measure space endowed with a vector bundle $TM$ as above. Let $\bar{L}$ be a non-negative self-adjoint operator acting on $L^2(M, d\mu; TM)$. Assume that $\bar{p}_z(x,y)$ is a continuous function of $x, y \in M$. Denote by $\bar{p}_z$, $z \in \mathbb{C}_+$, the kernel of $\exp(-z\bar{L})$. Let $V : \mathbb{R}_+ \times M \to \mathbb{R}_+$ be a continuous function satisfying condition (4.11). Assume that

$$V(x, \sqrt{t}) \text{Tr} \bar{p}_z(x,x) \leq 1 \quad \forall t > 0, \ x \in M. \quad (4.23)$$

Then

$$|\bar{p}_z(x,y)| \leq \frac{e^{K'}}{\sqrt{V(x, d(x, y)/2) V(y, d(y, x)/2)}} \left( \frac{d^2(x, y)}{4|z|} \right)^{\delta} \exp \left( -\text{Re} \frac{d^2(x, y)}{4z} \right) \quad (4.24)$$

for all $z \in \mathbb{C}_+$, $x, y \in M$ such that $\text{Re}d^2(x, y)/(4z) \geq 1$.

**Remark.** Of course, one can transform the above estimate in a similar way as in Corollary 4.5.

**Proof.** Note that the self-adjointness of $\exp(-t\bar{L})$ implies that $p_t(y, x) = [p_t(x, y)]^*$. Denote by $| \cdot |_\text{HS}$ the Hilbert–Schmidt norm of a linear operator. One can write

$$\text{Tr} \bar{p}_t(x,x) = \text{Tr} \int p_{t/2}(x,y)p_{t/2}(y,x)d\mu(y) = \text{Tr} \int p_{t/2}(x,y)[p_{t/2}(x,y)]^*d\mu(y) = \text{Tr} \left( p_{t/2}(x,y)[p_{t/2}(x,y)]^* \right) d\mu(y),$$

where $\bar{p}_t(x,x) = \text{Tr} \bar{p}_t(x,x)$.
Indeed, one also has since (4.27) and the identity $W$ defined by the formula $\|m_{W(\cdot)\sqrt{\tau}}\|_{1 \to \infty} \leq 1$, where $W(x, r) = \sqrt{V(x, r)}$, $x \in M$, $r > 0$. This estimate can be extended to complex times. Indeed, one also has

$$\int |\tilde{p}(x, z)|^2 d\mu(z) \leq \int |\tilde{p}_t(x, z)|^2_{HS} d\mu(z) \leq \frac{1}{V(x, t^{1/2})},$$

that is,

$$\|m_{W(\cdot)\sqrt{\tau}}\|_{2 \to \infty} = \|\exp(-t\bar{L})m_{W(\cdot)\sqrt{\tau}}\|_{1 \to 2} \leq 1 \quad \forall t > 0. (4.27)$$

Using the contractivity of $\exp(-i\tau L)$, $s \in \mathbb{R}$, on $L^2$, one has

$$\|m_{W(\cdot)\sqrt{\tau}}\|_{1 \to \infty} \leq \|\exp(-t\bar{L})m_{W(\cdot)\sqrt{\tau}}\|_{1 \to 2} \leq \|\exp(-t\bar{L})m_{W(\cdot)\sqrt{\tau}}\|_{1 \to 2} \leq \|\exp(-t\bar{L})m_{W(\cdot)\sqrt{\tau}}\|_{1 \to 2}.$$

Together with (4.27) and the identity $\|T^* T\|_{1 \to \infty} = \|T\|_{1 \to 2}^2$, this yields

$$\|m_{W(\cdot)\sqrt{\tau}}\|_{1 \to \infty} \leq 1 \quad \forall \tau \in \mathbb{C}_+. (4.28)$$

Similarly, as in (4.16), fix $x, y \in M$, and for $d(x, y) > 2s > 0$ set $r = d(x, y) - 2s$. Consider the function $F$ defined by the formula

$$F(z) = \langle \exp(-z\bar{L})m_{W(\cdot, r/2)}\omega_2, m_{W(\cdot, r/2)}\omega_1 \rangle,$$

with $\omega_1 \in L^1(B(x, s), d\mu; TM) \cap L^2(B(x, s), d\mu; TM)$, $\omega_2 \in L^1(B(y, s), d\mu; TM) \cap L^2(B(y, s), V(\cdot, r/2) d\mu; TM)$, and $\|\omega_1\|_1 = \|\omega_2\|_1 = 1$. By virtue of assumption (3.1) and Davies–Gaffney condition (3.2), $F$ satisfies (2.8) and (2.9) with $\gamma = r^2/4$ and

$$A = \|m_{W(\cdot, r/2)}\omega_1\|_2 \|m_{W(\cdot, r/2)}\omega_2\|_2 = \|\omega_1\|_{L^2(U_1,V(\cdot, r/2) d\mu)} \|\omega_2\|_{L^2(U_2,V(\cdot, r/2) d\mu)}.$$
Now if \( z \in \mathcal{C}_{r/4} \), then \( \sqrt{\text{Re} z} \leq r/2 \) by (4.17). Using the assumptions on \( \omega_1, \omega_2, W \) as well as (4.28), we obtain
\[
|F(z)| = |(m_{W(\cdot, r/2)} \exp(-z\tilde{L})m_{W(\cdot, r/2)} \omega_2, \omega_1)| \\
\leq \sup_{x,y \in M} \frac{W(x, \sqrt{\text{Re} z})W(y, \sqrt{\text{Re} z})}{W(x, \sqrt{\text{Re} z})W(y, \sqrt{\text{Re} z})} |(m_{W(\cdot, \sqrt{\text{Re} z})} \exp(-z\tilde{L})m_{W(\cdot, \sqrt{\text{Re} z})} \omega_2, \omega_1)| \\
\leq \sup_{x,y \in M} \frac{W(x, \sqrt{\text{Re} z})W(y, \sqrt{\text{Re} z})}{W(x, \sqrt{\text{Re} z})W(y, \sqrt{\text{Re} z})} \|m_{W(\cdot, \sqrt{\text{Re} z})} \exp(-z\tilde{L})m_{W(\cdot, \sqrt{\text{Re} z})} \|_{1 \to \infty} \\
\leq K' \left( \frac{r^2}{4\text{Re} z} \right)^{\delta/2}
\]
for all \( z \in \mathcal{C}_{r/4} \). Thus \( F \) satisfies (2.10) with \( B = K'2^{-\delta} \) and \( \nu = \delta \). By Proposition 2.3,
\[
|F(z)| \leq eK' \left( \frac{r^2}{4|z|} \right)^{\delta} \exp \left( -\text{Re} \frac{r^2}{4z} \right)
\]
for all \( z \in \mathcal{C}_{r/4} \). One finishes the proof as in Theorem 4.4, using Claim 4.8. \( \square \)

### 4.4. Gaussian estimates for the gradient of the heat kernel

The technique which we developed above can be applied to obtain Gaussian bounds for the gradient of the heat kernels. The following result is motivated by some considerations in [4, Section 1.4]. In particular, it is proved in [4] that under the assumptions below, for \( a = 1/2 \), the Riesz transform is bounded on \( L^p(M, d\mu) \) for \( 2 < p < +\infty \). In the language of [4], we will show now that, under \( (FK) \), conditions (1.7), (1.8) and \( (G) \) are all equivalent, which was left open there. A similar result was obtained independently in [30], by a different method, relying directly on the finite speed propagation property for the wave equation.

**Theorem 4.11.** Let \( M \) be a complete Riemannian manifold such that the Riemannian measure \( \mu \) satisfies the doubling condition (4.9), and let \( \Delta \) be the Laplace–Beltrami operator, \( p_z \) the corresponding heat kernel, \( \nabla \) the Riemannian gradient on \( M \). Suppose next that
\[
p_t(x, x) \leq \frac{C}{\mu(B(x, \sqrt{t}))} \quad \forall t > 0, \; x \in M, \tag{4.29}
\]
and that
\[
\sup_{x,y \in M} |\nabla p_t(x, y)| \mu(B(y, \sqrt{t})) \leq Ct^{-a} \tag{4.30}
\]
for some \( a > 0 \) and all \( t \in \mathbb{R}_+ \). Then
\[
|\nabla p_t(x, y)| \leq \frac{C}{t^a \mu(B(y, \sqrt{t}))} \left( 1 + \frac{d^2(x, y)}{4t} \right)^{3\delta+2a} \exp \left( -\frac{d^2(x, y)}{4t} \right) \tag{4.31}
\]
for all \( t > 0, \; x, y \in M \).

In the proof of Theorem 4.11 we shall need the following consequence of Corollary 4.5 and of the above assumptions.

**Lemma 4.12.** Assume (4.9), (4.29) and (4.30). Then
\[
\|\nabla \exp(-z\Delta)m_{V(\cdot, r)}\|_{1 \to \infty} = \sup_{x,y \in M} |\nabla p_z(x, y)| V(y, r) \leq C(\text{Re} z)^{-a} \left( \frac{|z|}{\text{Re} z} \right)^{2a} \left( \frac{r^2}{\text{Re} z} \right)^{\delta/2} \tag{4.32}
\]
for all $r > 0$, $z \in \mathcal{C}_{r^2/4}$, where $\delta > 0$ is the exponent in (4.10).

Proof. An immediate reformulation of (4.18) is

$$|p_z(x, y)| \leq \frac{cK'(1 + \text{Re} d^2(x, y)/(4z))^\delta}{\sqrt{V\left(x, (\text{Re } 1/z)^{-1/2}\right) V\left(y, (\text{Re } 1/z)^{-1/2}\right)}} \exp\left(-\text{Re} \frac{d^2(x, y)}{4z}\right) \left(\frac{|z|}{\text{Re } z}\right)^\delta,$$

which yields, for $0 < c < 1/4,$

$$|p_z(x, y)| \leq \frac{C}{\sqrt{V\left(x, (\text{Re } 1/z)^{-1/2}\right) V\left(y, (\text{Re } 1/z)^{-1/2}\right)}} \exp\left(-c\text{Re} \frac{d^2(x, y)}{z}\right) \left(\frac{|z|}{\text{Re } z}\right)^\delta,$$

and, by doubling,

$$|p_z(x, y)| \leq \frac{C'}{V\left(y, (\text{Re } 1/z)^{-1/2}\right)} \exp\left(-c'\text{Re} \frac{d^2(x, y)}{z}\right) \left(\frac{|z|}{\text{Re } z}\right)^\delta.$$

Take now $z = t + is \in \mathcal{C}_{r^2/4}$, where $t, s \in \mathbb{R}$. Note that $(t/2) + is \in \mathcal{C}_{r^2}$. Write

$$\nabla p_z(x, y) = \int_M \nabla p_{t/2}(x, u)p_{t/2+i}(u, y)d\mu(u),$$

and hence, using (4.4), (4.30), and doubling,

$$|\nabla p_z(x, y)| \leq \frac{C}{t^2 V\left(y, (\text{Re } 1/z)^{-1/2}\right)} \left(\frac{|z|}{\text{Re } z}\right)^\delta \frac{1}{V(y, \sqrt{t})} \int_M \frac{1}{V(u, \sqrt{t})} \exp\left(-c'\text{Re} \frac{d^2(u, y)}{z}\right) d\mu(u).$$

Let us estimate

$$I = \int_M \frac{1}{V(u, \sqrt{t})} \exp\left(-c'\text{Re} \frac{d^2(u, y)}{z}\right) d\mu(u).$$

Since $(\text{Re } 1/z)^{-1/2} \geq (\text{Re } z)^{1/2} = \sqrt{t}$, one has

$$I \leq K'\left(\frac{\text{Re } 1/z)^{-1/2}}{\sqrt{\text{Re } z}}\right)^{\delta/2} II = \left(\frac{|z|}{\text{Re } z}\right)^\delta II,$$

where

$$II = \int_M \frac{1}{V\left(u, (\text{Re } 1/z)^{-1/2}\right)} \exp\left(-c'\text{Re} \frac{d^2(u, y)}{z}\right) d\mu(u)$$

is easily seen to be uniformly bounded in $y \in M$, $z \in \mathbb{C}_+$ by doubling. Thus

$$|\nabla p_z(x, y)| \leq \frac{C}{t^2 V\left(y, (\text{Re } 1/z)^{-1/2}\right)} \left(\frac{|z|}{\text{Re } z}\right)^{2\delta}.$$

Now, for $z \in \mathcal{C}_{r^2}$, $r \geq (\text{Re } 1/z)^{-1/2} \geq (\text{Re } z)^{1/2}$, and hence

$$\frac{V(y, r)}{V\left(y, (\text{Re } 1/z)^{-1/2}\right)} \leq \frac{V(y, r)}{V\left(y, (\text{Re } z)^{1/2}\right)} \leq K'\left(\frac{r^2}{\text{Re } z}\right)^{\delta/2};$$

therefore

$$|\nabla p_z(x, y)| V(y, r) \leq C (\text{Re } z)^{-\delta} \left(\frac{r^2}{\text{Re } z}\right)^{\delta/2} \left(\frac{|z|}{\text{Re } z}\right)^{2\delta},$$

which is the claim.
Proof of Theorem 4.11. As before, fix \( x, y \in M \) and, for \( 0 < 2s < d(x, y) \), let \( r = d(x, y) - 2s \). Next fix \( f \in L^2(B(x, s), d\mu) \cap L^1(B(x, s), d\mu) \) and let \( X \in TM \) be a smooth vector field on \( M \) supported in \( B(y, s) \). This time we set, for \( z \in \mathbb{C}_+ \),

\[
F(z) = \langle \nabla \exp(-z\Delta) m_{V(\cdot, r)} f, X \rangle,
\]

where \( V(x, r) = \mu(B(x, r)) \). Now

\[
F(z) = \langle \exp(-z\Delta) m_{V(\cdot, r)} f, \nabla^* X \rangle = \langle \exp(-z\Delta) m_{V(\cdot, r)} f, \text{div} X \rangle.
\]

Therefore, since \( \Psi(z) = e^{-z\Delta} \) satisfies (3.1) and (3.2), it follows that \( F \) satisfies (2.8) and (2.9) with

\[
A = \| m_{V(\cdot, r)} f \|_2 \| \text{div} X \|_2 \quad \text{and} \quad \gamma = r^2/4.
\]

Note that \( A \) is finite since \( \text{div} X \) is smooth and supported in \( B(y, s) \). Now assume in addition that \( \|f\|_1 = \||X||_1 = 1 \) and let \( z \in \mathbb{C}_{r^2/4} \). By Lemma 4.12,

\[
|F(z)| \leq \| \nabla \exp(-z\Delta) m_{V(\cdot, r)} \|_{1 \to \infty} \leq C(\text{Re} z)^{-a} \left( \frac{|z|}{\text{Re} z} \right)^{2\delta/2} \exp \left( -\frac{r^2}{4|z|} \right)
\]

for all \( z \in \mathbb{C}_{r^2/4} \). Thus \( F \) satisfies the assumptions of Proposition 2.4 with

\[
B = Cr^{-2a - \delta/2}, \quad \nu = 5\delta + 2a, \quad \gamma = r^2/4 \quad \exp(g(z)) = z^{-2\delta}, \quad \text{and any } \beta \in (0, 1).
\]

Therefore

\[
|F(z)| \leq eCr^{-2a - \delta/2} \left( \frac{r^2}{2|z|} \right)^{5\delta + 2a} |z|^{2\delta} \exp \left( -\frac{r^2}{4|z|} \right)
\]

for all \( z \in \mathbb{C}_{r^2/4} \). An obvious modification of Claim 4.8 yields

\[
|\nabla p_z(x, y)|V(x, r) \leq \sup_{x' \in B(x(s), y) \in B(y, s)} |\nabla p_z(x', y')|V(y', r) = \sup \{ |F(z)| : \|f\|_{L^1(B(x, s), d\mu)} = \|X\|_{L^1(B(y, s), d\mu)} = 1 \} \leq Cr^{-2a} \left( \frac{r^2}{4|z|} \right)^{3\delta + 2a} \exp \left( -\frac{r^2}{4|z|} \right),
\]

and letting \( s \) go to 0 we obtain

\[
|\nabla p_z(x, y)|V(y, d(x, y)) \leq C(d^2(x, y))^{-a} \left( \frac{d^2(x, y)}{4|z|} \right)^{3\delta + 2a} \exp \left( -\frac{d^2(x, y)}{4|z|} \right)
\]

for all \( z \in \mathbb{C}_{d^2(x, y)/4} \). If \( 0 \leq t \leq d^2(x, y)/4 \) then \( V(y, \sqrt{t}) \leq V(y, d(x, y)/2) \), and so by (4.33)

\[
|\nabla p_z(x, y)|V(y, \sqrt{t}) \leq Ct^{-a} \left( \frac{d^2(x, y)}{4t} \right)^{3\delta + 2a} \exp \left( -\frac{d^2(x, y)}{4t} \right)
\]

for all \( 0 \leq t \leq d^2(x, y)/4 \). For \( t \geq d^2(x, y)/4 \), (4.31) is immediate from (4.30).

\[\square\]

Remark. Note that (4.33) also yields complex time estimates for the gradient of the heat kernel.

4.5. Families of operators without semigroup property

An important advantage of the technique which we discuss here is that we do not have to assume that the family \( \{ \Psi(z) : z \in \mathbb{C}_+ \} \) under consideration has the semigroup property. Hence we are able to apply our results to families of operators which can be defined by: \( \Psi(z) = g(z) \exp(-zL), \) where \( g : \mathbb{C}_+ \to \mathbb{C} \) is an analytic function; \( \Psi(z) = \exp(-zL_1) \exp(-zL_2); \)

THIERRY COULHON AND ADAM SIKORA
\[ \Psi(z) = \exp(-zL_1) - \exp(-zL_2) \] or some more complex formulae. To be more precise, let us come back to the general metric measure space setting, and consider an analytic family of operators \( \{\Psi(z) : z \in \mathbb{C}_+\} \) acting on \( L^2(M, d\mu) \). Next assume that (see (4.1))
\[ \|\Psi(z)\|_{1 \rightarrow \infty} \leq K(Re z)^{-D/2} \quad \forall z \in \mathbb{C}_+. \] (4.34)

By [29, Theorem 6, p. 503] we can define the kernel \( p_z^\Psi \) of the operator \( \Psi(z) \) in the same way as in (4.2) and again assume that \( p_z^\Psi \) is a continuous function on \( M^2 \). Now we can state the following version of Theorem 4.2.

**Theorem 4.13.** Suppose that the family \( \{\Psi(z) : z \in \mathbb{C}_+\} \) satisfies conditions (3.1), (3.2) and (4.34). Then the kernel \( p_z^\Psi \), if continuous, satisfies estimates (4.5).

The proof of Theorem 4.13 is the same as the proof of Theorem 4.2.

For instance, let \( L \) be a self-adjoint uniform elliptic second-order differential operator in divergence form with periodic coefficients acting on \( L^2(\mathbb{R}^n) \), and let \( L^0 \) be the corresponding homogenized operator. Next let \( p_z \) and \( p_z^0 \) be the corresponding heat kernels. Then a straightforward modification of the argument from [61] shows the following so-called Berry–Esseen–type estimate
\[ |p_z(x, y) - p_z^0(x, y)| \leq K \min \left\{ 1, \frac{|z|}{(Re z)^{3/2}} \right\} (Re z)^{-n/2} \] (4.35)
for all \( z \in \mathbb{C}_+ \), \( x, y \in \mathbb{R}^n \). The following consequence of Theorem 4.13 can be used to obtain Gaussian bounds for the expression \( |p_z(x, y) - p_z^0(x, y)| \).

**Example 4.14.** Suppose that \( L \) and \( L^0 \) are two generators of analytic semigroups on \( L^2(\mathbb{R}^n) \). Next assume that \( L \) and \( L^0 \) satisfy conditions (3.1), (3.2) with the distances \( d \) and \( d^0 \). Finally suppose that the corresponding heat kernels satisfy estimate (4.35) and set \( d(x, y) = \min\{d(x, y), d^0(x, y)\} \). Then
\[ |p_z(x, y) - p_z^0(x, y)| \leq \frac{eK \min \left\{ 1, \frac{|z|}{(Re z)^{3/2}} \right\}}{(Re z)^{n/2}} \left( 1 + Re \frac{d^2(x, y)}{4z} \right)^{(n+3)/2} \exp \left( -Re \frac{d^2(x, y)}{4z} \right) \]
for all \( z \in \mathbb{C}_+ \), \( x, y \in \mathbb{R}^n \).

**Proof.** It easy to note that if for \( z \in \mathbb{C}_+ \) we put \( \Psi(z) = \exp(-zL) - \exp(-zL^0) \) then \( \Psi \) satisfies (3.1) and (3.2) with the distance \( d \) (and with constant 2). Hence Example 4.14 follows from Proposition 2.4, with \( \exp(g(z)) = z \) and \( \nu = n + 3 \). Note that with this choice of \( g \), estimate (2.14) is satisfied for any \( \beta > 0 \), for some constants \( C \) and \( c \) depending on \( \gamma \) and \( \beta \).

**Remark.** As we already said, the fact that the exponent in the polynomial correction factor in front of the exponential in (4.5) cannot be improved to \((D - 1)/2\) as in [53], is related to the fact that the proof of Theorem 4.2 does not use the fact that the family of operators under consideration is a semigroup; in other words it is related to the possibility of extending Theorem 4.2 to Theorem 4.13. Indeed, let \( L \) be the standard Laplace operator acting on \( \mathbb{R}^n \), and apply Theorem 4.13 to the family of operators \( \Psi(z) = z^{n/2} \exp(-zL), z \in \mathbb{C}_+ \). In this case \( D = 0 \) in (4.34), and the conclusion cannot hold with \((D - 1)/2 = -1/2\) in the polynomial correction factor in front of the exponential, since in that case \( p_z(x, y) \) is exactly given by the Gauss function. By contrast, the argument from [53] cannot be applied to this choice of \( \Psi(z) \), because it only applies to semigroups.
A more elementary example is the following. Let \( M = \{x, y\} \) with counting measure and let \( d(x, y) = 1 \). Consider the analytic family of operators \( \{\Psi(z) : z \in \mathbb{C}_+\} \) acting on \( L^2(M) \) given by the kernel \( p_z(x, x) = p_z(y, y) = 0 \) and \( p_z(x, y) = p_z(y, x) = \exp(-1/(4z)) \). It is easy to check that the family \( \{\Psi(z) : z \in \mathbb{C}_+\} \) satisfies conditions (3.1), (3.2) and (4.34) with \( D = 0 \). Again, this shows that the exponent \( D/2 \) cannot be replaced by \((D - 1)/2\) in the setting of Theorem 4.13.

4.6. \( L^p \to L^q \) Gaussian estimates

Claim 4.1 reduces the proof of Gaussian bounds for the heat kernel to obtaining a Gaussian-type estimate for expressions of the form
\[
\sup \left\{ \| \langle \exp(-zL) f_1, f_2 \rangle \| : \| f_1 \|_{L^1(U_1, d\mu)} = \| f_2 \|_{L^1(U_2, d\mu)} = 1 \right\}.
\]
In such expressions, one can replace the \( L^1 \) norms of functions \( f_1 \) and \( f_2 \) by the \( L^p \) norm of \( f_1 \) and the \( L^q \) norm of \( f_2 \), for \( 1 \leq p, q \leq +\infty \). This leads to natural generalizations of pointwise Gaussian bounds and provides some form of Gaussian bounds for semigroups without heat kernels. There are many interesting examples of operators which generate such semigroups. More precisely, the corresponding semigroup \( \exp(-tL) \) is not bounded from \( L^1 \) to \( L^\infty \) even locally. The kernel of the operator \( \exp(-tL) \) can always be defined as a distribution or in some other sense, but in such cases it is not a bounded function. Often such operators generate bounded semigroups on \( L^p \) spaces only for \( p \) ranging in some proper subinterval of \([1, \infty] \). We discuss a semigroup of this type in Example 4.17 below.

The so-called generalized Gaussian bounds that such semigroups may satisfy were studied, for instance, by Davies in [27, Lemmas 23 and 24], and they were extensively discussed by Blunck and Kunstmann (see [9–13]). Estimates of a similar nature were also considered in [46]; see Propositions 2.6 and 2.8 in this paper. For interesting considerations about \( L^p - L^q \) Gaussian estimates, see also [5].

As in Section 4.5, we consider analytic families of operators \( \{\Psi(z) : z \in \mathbb{C}_+\} \) on metric measure spaces rather than semigroups generated by self-adjoint operators. Still the case \( \Psi(z) = \exp(-zL) \) is the most natural example. In this section we are going to consider families of operators satisfying the condition
\[
\| m_{W_1(\cdot, \sqrt{\text{Re}z})} \Psi(z) m_{W_2(\cdot, \sqrt{\text{Re}z})} \|_{p \to q} \leq 1 \quad \forall z \in \mathbb{C}_+, \quad (4.36)
\]
where \( 1 \leq p < q \leq +\infty \), and the functions \( W_i \) satisfy condition (4.11) with exponents \( \delta_i/2 \) for \( i = 1, 2 \). We discuss the rationale for condition (4.36) in Remark (b) after Theorem 4.15. Now let us notice only that if \( \Psi(z) = \exp(-zL) \), \( p = 1 \), \( q = \infty \) and \( W_1 = W_2 = V^{1/2} \), then estimates (4.36) are equivalent to estimates (4.14), which follow as we have seen from condition (4.12). Hence one can think of condition (4.36) as a generalization of the on-diagonal estimates (4.12).

**Theorem 4.15.** Let \( (M, d, \mu) \) be a metric measure space. Suppose that the functions \( W_i : \mathbb{R}_+ \times M \to \mathbb{R}_+ \), \( i = 1, 2 \), are continuous and satisfy condition (4.11) with constants \( \sqrt{K_i} \geq 1 \) and exponents \( \delta_i/2 \). Next assume that the analytic family \( \{\Psi(z) : z \in \mathbb{C}_+\} \) of operators on \( L^2(M, d\mu) \) satisfies conditions (3.1), (3.2) as well as (4.36) for some \( p, q \), \( 1 \leq p < q \leq +\infty \). Then
\[
\| P_i m_{W_1(\cdot, r/2)} \Psi(z) m_{W_2(\cdot, r/2)} P_i \|_{p \to q} \leq e \sqrt{K_1 K_2} \left( \frac{r^2}{4|z|} \right)^{\delta_1 + \delta_2} \exp\left(-\text{Re} \left( \frac{r^2}{4z} \right) \right) \quad (4.37)
\]
for all \( U_1, U_2 \) open subsets of \( M \) and all \( z \in \mathbb{C}_{r^2/4} \), with \( r = d(U_1, U_2) \). Here \( P_i \) denotes the operator of multiplication by the characteristic function of the sets \( U_i \subset M \), that is, \( P_i = m_{\chi_{U_i}} \).
for $i = 1, 2$. Moreover
\[
\|P_t m_{\mathcal{W}_1(z, \sqrt{t})} \Psi(t) m_{\mathcal{W}_2(z, \sqrt{t})} p\|_{p \to q} \leq e^{\sqrt{K'_1 K'_2}} \left(1 + \frac{r^2}{4t}\right)^{\frac{\gamma}{2}} \exp \left(-\frac{r^2}{4t}\right)
\]
(4.38)
for all $t \in \mathbb{R}_+$.

**Proof.** Similarly as in (4.16) we consider the function $F$ defined by the formula
\[
F(z) = (\Psi(z) m_{\mathcal{W}_2(z, \sqrt{t})} f_2, m_{\mathcal{W}_1(z, \sqrt{t})} f_1),
\]
but now assume that $f_i \in L^2(U_i, W_i^2(\cdot, r/2) d\mu)$ for $i = 1, 2$ and $\|f_1\|_{L^q(U_1, d\mu)} = \|f_2\|_{L^q(U_2, d\mu)} = 1$, where $1/q + 1/q' = 1$.

By virtue of assumption (3.1) and Davies–Gaffney condition (3.2), $F$ satisfies (2.8) and (2.9) with $\gamma = r^2/4$ and
\[
A = \|m_{\mathcal{W}_1(z, \sqrt{t})} f_1\|_2 \|m_{\mathcal{W}_2(z, \sqrt{t})} f_2\|_2 = \|f_1\|_{L^2(U_1, W_i^2(\cdot, r/2) d\mu)} \|f_2\|_{L^2(U_2, W_i^2(\cdot, r/2) d\mu)}.
\]
Now if $z \in C_{r^2/4}$, then $\sqrt{Re z} \leq r/2$ by (4.17). Using the assumptions on $f_1, f_2, W_1, W_2$ as well as (4.36), we obtain
\[
|F(z)| = |(m_{\mathcal{W}_1(z, \sqrt{t})} \Psi(z) m_{\mathcal{W}_2(z, \sqrt{t})} f_2, f_1)| \leq \sup_{x,y \in M} W_1(x, \sqrt{Re z}) W_2(y, \sqrt{Re z}) \|m_{\mathcal{W}_1(z, \sqrt{Re z})} \Psi(z) m_{\mathcal{W}_2(z, \sqrt{Re z})}\|_{p \to q}
\leq \sqrt{K'_1 K'_2} \left(\frac{r^2}{4 Re z}\right)^{(\delta_1 + \delta_2)/2} = \sqrt{K'_1 K'_2} 2^{-(\delta_1 + \delta_2)/2} \left(\frac{Re z}{r^2}\right)^{-(\delta_1 + \delta_2)/2}
\]
for all $z \in C_{r^2/4}$. Thus $F$ satisfies (2.10) with $B = \sqrt{K'_1 K'_2} 2^{-(\delta_1 + \delta_2)}$ and $\nu = \delta_1 + \delta_2$. By Proposition 2.3,
\[
|F(z)| \leq e^{\sqrt{K'_1 K'_2} 2^{-(\delta_1 + \delta_2)} \left(\frac{r^2}{2|z|}\right)^{\delta_1 + \delta_2} \exp \left(-Re \frac{r^2}{4z}\right)}.
\]
The spaces $L^1(U_i, d\mu) \cap L^2(U_i, W_i^2(\cdot, r/2) d\mu)$, being dense in $L^q(U_i, d\mu)$ (and $L^p(U_2, d\mu)$), the above inequality, for all functions $f_i \in L^2(U_i, W_i^2(\cdot, r/2) d\mu)$, $i = 1, 2$, such that $\|f_1\|_{L^q} = \|f_2\|_{L^p} = 1$, yield (4.37).

To prove (4.38) we notice that for $t \leq r^2/4$, it is a straightforward consequence of (4.37). For $t \geq r^2/4$, it follows from (4.36).

**Remark.** (a) Note that if $\Psi(z) = \exp(-zL)$, $1/p + 1/p' = 1$ and $W_1 = W_2 = W$, then it is enough to assume that (4.36) holds for $z = t \in \mathbb{R}_+$, indeed. By using, as in the proof of Theorem 4.10, the identity $\|T^s T\|_{p \to p'} = \|T\|_{p \to 2}^2$ and the contractivity of $\exp(-isL)$, $s \in \mathbb{R}$, on $L^2(M, d\mu)$, one obtains
\[
\|m_{\mathcal{W}_1(z, \sqrt{Re z})} \exp(-zL) m_{\mathcal{W}_2(z, \sqrt{Re z})}\|_{p \to p'} = \|m_{\mathcal{W}_1(z, \sqrt{Re z})} \exp(-(Re z)L) m_{\mathcal{W}_2(z, \sqrt{Re z})}\|_{p \to p'}.
\]
(b) In [9–13], Blunck and Kunstmann developed spectral multiplier theorems for operators which generate semigroups without heat kernel acting on spaces satisfying the doubling condition (here we discuss only second-order operators; Blunck and Kunstmann also consider the $m$th-order version of generalized Gaussian estimates). As their basic assumption they consider the following form of generalized Gaussian estimates:
\[
\|m_{\chi_{B(x, \sqrt{t})}} \exp(-tL) m_{\chi_{B(y, \sqrt{t})}}\|_{p \to q} \leq CV(x, y) 1/q - 1/p \exp \left(-\frac{d^2(x, y)}{t}\right) \forall t > 0, x, y \in M,
\]
(4.39)
where $1 \leq p \leq 2 \leq q \leq +\infty$ and $V(x, r) = \mu(B(x, r))$. The above estimates imply that
\[
\|\exp(-tL) \mathbf{m}_{V^{(1/2)-(1/p)}(\cdot, \sqrt{t})}\|_{p \to 2} \leq C \quad \text{and} \quad \|\mathbf{m}_{V^{(1/2)-(1/p)}(\cdot, \sqrt{t})} \exp(-tL)\|_{2 \to q} \leq C \quad (4.40)
\]
(see [13, Proposition 2.1, (ii)]). It follows from the above considerations that the opposite implication is valid if $(M, d, \mu, L)$ satisfies conditions (3.1) and (3.2). Indeed, estimates (4.40) imply (4.36) with $W_1 = V^{(1/2)-(1/q)}(\cdot, \sqrt{t})$ and $W_2 = V^{(1/p)-(1/2)}(\cdot, \sqrt{t})$. Now, according to Theorem 4.15, estimate (4.40) implies the estimates (4.38), which in turn imply (4.39) by choosing $U_1 = B(x, \sqrt{t})$, $U_2 = B(y, \sqrt{t})$ and using doubling. Thus Theorem 4.15 can be used to verify the main assumption of the results obtained in [9–13]. For example, the next statement follows from [10, Theorem 1.1] and Theorem 4.15 (see also [15, Theorem 4.3], for a more primitive version, with an additional $\varepsilon$ in the resulting exponent). We give below a proof that follows directly from Theorem 4.15. The conclusion of the corollary is instrumental in the theory of Riesz means (see [10, 15], and references therein); see also condition $(HG_\alpha)$, in [33, p. 339] and its consequences.

**Corollary 4.16.** Suppose that $(M, d, \mu, L)$ satisfies the doubling condition (4.9), as well as conditions (3.1) and (3.2). Let $p \in [1, 2]$, and assume that there exists $C > 0$ such that
\[
\|\exp(-tL) \mathbf{m}_{V^{(1/p)-(1/2)}(\cdot, \sqrt{t})}\|_{p \to 2} \leq C \quad \forall t \in \mathbb{R}_+,
\]
where $V(x, r) = \mu(B(x, r))$. Then there exists $C > 0$ such that
\[
\|\exp(-zL)\|_{\tilde{p} \to \tilde{p}} \leq C \left(\frac{|z|}{\Re z}\right)^{\delta|1/\tilde{p}-1/2|} \quad \forall z \in \mathbb{C}_+, \quad \tilde{p} \in [p, p'],
\]
where $\delta$ is the exponent in condition (4.10).

**Proof.** Note that, for all $p \in [1, \infty],$
\[
\sum_k \left(\sum_l |c_k a_l|^p\right)^{\frac{1}{p}} \leq \left(\max \left\{\sup_k \sum_l |c_k|, \sup_k \sum_l |c_l|\right\}\right)^{p} \sum_n |a_n|^p,
\]
with the obvious meaning for $p = \infty$, where $c_k$, $a_l$ are sequences of real or complex numbers. Indeed, for $p = 1$ and $p = \infty$, estimate (4.42) is easy to obtain. Then we obtain (4.42) for all $1 \leq p \leq \infty$ by interpolation. Let $z \in \mathbb{C}_+$ and set $r^2 = 4(\Re z)^{-1}$, that is, $r = 2|z|/\sqrt{\Re z}$. Let $x_k$ be a maximal sequence in $M$ such that all the balls $B(x_k, r/2)$ are disjoint. Note that the balls $B(x_k, r)$ are such that $\bigcup_k B(x_k, r) = M$, and that by doubling there exists $N \in \mathbb{N}^*$ such that any $x \in M$ is contained in at most $N$ such balls. Let $\chi_k$ be the characteristic function of the set $B_k = B(x_k, r) \setminus \bigcup_{l=1}^{k-1} B(x_l, r)$, and set $r_{lk} = d(B_k, B_l)$. Using Jensen and doubling, we may write
\[
\|\exp(-zL)f\|_{p}^p \leq \sum_k \left(\sum_l \|\chi_k \exp(-zL)(\chi_l f)\|_{p}\right)^{p} \leq C \sum_k \left(\sum_l V(x_k, r)^{1/p-1/2}\|\mathbf{m}_{\chi_k} \exp(-zL)\|_{p \to 2}\|\chi_l f\|_{p}\right)^{p},
\]
and hence by (4.42)
\[
\|\exp(-zL)f\|_{p}^p \leq C \max\{1, \Pi\}\|f\|_{p}^p,
\]
where
\[
I = \sup_{l} \sum_{k} V(x_k, r)^{1/p - 1/2} \| m_{x_k} \exp(-zL)m_{x_l}\|_{p \to 2},
\]
\[
II = \sup_{l} \sum_{k} V(x_k, r)^{1/p - 1/2} \| m_{x_k} \exp(-zL)m_{x_l}\|_{p \to 2}.
\]

Thus \(\| \exp(-zL)f\|_{p \to p} \leq C \max\{I, II\}\), and our aim is to estimate from above I and II by \(C (|z|/\Re z)^{\delta(1/p - 1/2)}\); the result for the other values of \(\rho\) follows by duality and interpolation. We shall explain how one deals with I, the treatment of II being similar. Write
\[
\Psi(z) = \exp\left(\frac{\sqrt{|zL|}}{|z|} \frac{\Re z}{|z|} \right),
\]
thus
\[
\| \exp(-zL)f\|_{p \to p} \leq C \max\{I, II\},
\]
and our aim is to estimate from above I and II by \(C (|z|/\Re z)^{\delta(1/p - 1/2)}\); the result for the other values of \(\rho\) follows by duality and interpolation.

Observe first that there exists \(C\) only depending on the doubling constant so that, for all \(l\), \(#\{k; r_{kl} \leq r\} \leq C\).

Therefore
\[
III \leq C \sup_{\{k, l; r_{kl} \leq 2r\}} V(x_k, r)^{1/p - 1/2} \| m_{x_k} \exp(-zL)m_{x_l}\|_{p \to 2}.
\]

The conclusion of the corollary is trivial for \(p = 2\), and therefore we can assume \(1 \leq p < 2\).

Using the contractivity of \(\exp(-isL)\) on \(L^2(M, d\mu)\), one sees that (4.41) implies (4.36), with \(\Psi(z) = \exp(-zL), q = 2, W_1 = 1\) and \(W_2 = V^{(1/p) - (1/2)}\).

Thus
\[
\| m_{x_k} \exp(-zL)m_{x_l}\|_{p \to 2} \leq \| \exp(-zL)m_{x_l}\|_{p \to 2}
\]
\[
\leq \| \exp(-zL)m_{V^{(1/p) - (1/2)}(\cdot, \sqrt{\Re z})}\|_{p} \| m_{V^{(1/2) - (1/2)}}\|_{p}
\]
\[
\times \sup_{x \in \mathcal{B}_1} V^{1/2 - 1/p}(x, \sqrt{\Re z}).
\]

Hence, if \(r_{kl} \leq 2r\), then
\[
III \leq C \sup_{\{k, l; r_{kl} \leq 2r\}} V(x_k, r)^{1/p - 1/2} \| m_{x_k} \exp(-zL)m_{x_l}\|_{p \to 2}
\]
\[
\leq C \sup_{\{k, l; r_{kl} \leq 2r\}} \left( \frac{V(x_k, r)}{V(x, \sqrt{\Re z})} \right)^{1/p - 1/2}
\]
\[
\leq C \sup_{\{k, l; r_{kl} \leq 2r\}} \left( \frac{V(x, 4r + r_{kl})}{V(x, \sqrt{\Re z})} \right)^{1/p - 1/2}
\]
\[
\leq C \left( \frac{V(x, 6r)}{V(x, \sqrt{\Re z})} \right)^{1/p - 1/2}
\]
\[
\leq C(r/\sqrt{\Re z})^{\delta(1/p - 1/2)}
\]
\[
\leq C(|z|/\Re z)^{\delta(1/p - 1/2)}.
\]

In the last inequality, we could use doubling since \(r = 2|z|/\sqrt{\Re z} \geq \sqrt{\Re z}\).
Now for IV. Again, there exists $C$ only depending on the doubling constant so that, for all $l$, $\# \{ k: r_{kl} \leq ir \} \leq C i^\delta$.

Therefore

$$ IV \leq C \sum_{i=1}^{\infty} i^\delta \sup_{\{ k: 2i r < r_{kl} \leq 2(i+1)r \}} V^{1/p-1/2}(x_k, r) \| \mathbf{m}_{x_k} \exp(-zL) \mathbf{m}_{x_l} \|_{p=2} $$

Let us now estimate $\| \mathbf{m}_{x_k} \exp(-zL) \mathbf{m}_{x_l} \|_{p=2}$ for $r_{kl} > 2r$ with the help of Theorem 4.15. Note that $\delta_1 = 0$ and $\delta_2 = \delta (1/p - 1/2)$, where $\delta$ is the exponent in (4.10).

With our choice of $r$, we have $z \in C_{r_{kl}/4}$ as soon as $r_{kl} \geq r$. Therefore (4.37) yields

$$ \| \mathbf{m}_{x_k} \exp(-zL) \mathbf{m}_{x_l} \|_{p=2} \leq C \left( \frac{r_{kl}}{4|z|} \right)^{\delta(1/p-1/2)} \exp \left( -\frac{r_{kl}^2}{4z} \right) \| \mathbf{m}_{V^{(1/p)-(1/2)}(r_{kl}/2)} \mathbf{m}_{x_l} \|_{p=p} $$

Now

$$ \| \mathbf{m}_{V^{(1/p)-(1/2)}(r_{kl}/2)} \mathbf{m}_{x_l} \|_{p=p} \leq \sup_{x \in B_{l}} V^{1/2-1/p}(x, r_{kl}/2) $$

$$ \leq \left( \inf_{x \in B_{l}} V(x, r_{kl}/2) \right)^{1/2-1/p} $$

$$ \leq V^{1/p-1/2}(x_l, (r_{kl}/2) - r) $$

$$ \leq V^{1/p-1/2}(x_l, (i-1)r) $$

Thus, if $2ir < r_{kl} \leq 2(i+1)r$,

$$ \| \mathbf{m}_{x_k} \exp(-zL) \mathbf{m}_{x_l} \|_{p=2} \leq \left( \frac{r_{kl}^2}{4|z|} \right)^{\delta(1/p-1/2)} \exp \left( -\frac{r_{kl}^2}{4z} \right) V^{1/2-1/p}(x_l, (i-1)r) $$

$$ \leq V^{1/2-1/p}(x_l, (i-1)r) \left( \frac{(i+1)^2r^2}{|z|} \right)^{\delta(1/p-1/2)} \exp \left( -\frac{r^2}{4z} \right) e^{4i^2} $$

Finally,

$$ IV \leq C \sum_{i=2}^{\infty} i^\delta \sup_{2ir < r_{kl} \leq 2(i+1)r} \left( \frac{V(x_k, r)}{V(x_l, (i-1)r)} \right)^{1/p-1/2} \left( \frac{(i+1)^2r^2}{|z|} \right)^{\delta(1/p-1/2)} e^{4i^2} $$

By doubling,

$$ \left( \frac{V(x_k, r)}{V(x_l, (i-1)r)} \right)^{1/p-1/2} \leq \left( \frac{V(x_l, 3r + r_{kl})}{V(x_l, (i-1)r)} \right)^{1/p-1/2} \leq \left( \frac{V(x_l, (2i+5)r)}{V(x_l, (i-1)r)} \right)^{1/p-1/2} $$

is uniformly bounded. Therefore

$$ IV \leq C \sum_{i=2}^{\infty} i^\delta \left( \frac{(i+1)^2r^2}{|z|} \right)^{\delta(1/p-1/2)} e^{4i^2} \leq C \sum_{i=2}^{\infty} e^{-4i^2/(1+\varepsilon)} \left( \frac{|z|}{\text{Re} z} \right)^{\delta(1/p-1/2)} $$

which completes the proof.

We conclude this section with the description of a simple and natural example of a family of operators which generate semigroups without heat kernel. We consider the family of self-adjoint operators

$$ L(c) = \Delta - c|x|^{-2} $$
acting on $L^2(\mathbb{R}^n)$ for $n \geq 3$, where $\Delta = -\sum_{i=1}^{n} \partial^2_{x_i}$, and $0 \leq c \leq (n-2)^2/4$. Hardy’s inequality shows that
\[
\Delta \geq (n-2)^2/4|x|^2,
\]
in the Hilbertian sense, where $(n-2)^2/4|x|^2$ stands for the multiplication operator (see for example [59, (2.1), p. 107]). Hence, for all $c \in [0, (n-2)^2/4]$, $L^{(c)}$ is non-negative. A detailed discussion of the definition of the operators $L^{(c)}$ can be found, for example, in [3]. Such operators are called Schrödinger operators with the inverse-square potential and they are of substantial interest in analysis (see, for example, [6, 14, 45, 59] and references therein). Note that $L^{(c)}$ is homogeneous of order 2, meaning that if $U_t$ is the dilation $(U_tf)(x) = f(tx)$, $t > 0$, $x \in \mathbb{R}^n$, then $U_{1/t}L^{(c)}U_t = t^2L^{(c)}$ for all $t > 0$. As a consequence,
\[
\|\exp(-tL^{(c)})\|_{q\to p} = t^{n/2(1/q-1/p)} \|\exp(-L^{(c)})\|_{q\to p}.
\]
Set
\[
C_{c, p, q} = \|\exp(-L^{(c)})\|_{p\to q}.
\]
It was proved in [59, Corollary 6.2] that $C_{c, p, q} = \infty$ for all $p \leq q$ and $q > p_c = n/\sigma_c$, where
\[
\sigma_c = \frac{n-2}{2} - \sqrt{\frac{(n-2)^2}{4} - c}.
\]
It means in particular that for every $t > 0$ the operator $\exp(-tL^{(c)})$ cannot be extended to a bounded operator on $L^p(\mathbb{R}^n)$ for $p > p_c$, and hence $L^{(c)}$ does not generate a semigroup on $L^p(\mathbb{R}^n)$ for such $p$. It also means that for every $t > 0$ the operator $\exp(-tL^{(c)})$ cannot be extended to a bounded operator from $L^1(\mathbb{R}^n)$ to $L^\infty(\mathbb{R}^n)$: its kernel is not a bounded function on $\mathbb{R}^{2n}$ but has singularities as each variable approaches zero. Therefore standard heat kernel theory cannot be applied to study the semigroup generated by $L^{(c)}$. However, it was proved in [43] (see also [46, Section 4, 60, example 3.3]) that $\|\exp(-tL^{(c)})\|_{p\to p} = \|\exp(-L^{(c)})\|_{p\to p}$ is finite for all $p$ in the interval $(p_c', p_c)$ and all $t > 0$.

Our main interest here is some form of Gaussian-type estimates which we can obtain for $L^{(c)}$ even though we know that the pointwise Gaussian estimates cannot hold. Our $L^p \to L^q$ Gaussian estimates are described in the following example.

**Example 4.17.** Suppose that $c < (n-2)^2/4$ and that $p_c' < p < 2 < q < p_c$, where $1/p_c + 1/p_c' = 1$, $p_c = n/\sigma_c$ and $\sigma_c = (n-2)/2 - \sqrt{(n-2)^2/4 - c}$. Then there exists a constant $C$ such that for any two open subsets of $U_1, U_2 \subset \mathbb{R}^n$, the following estimates hold:
\[
\|P_1 \exp(-zL^{(c)}) P_2\|_{p\to q} \leq C(\text{Re } z)^{-\nu} \left(1 + \frac{r^2}{4z}\right)^\nu \exp\left(-\frac{r^2}{4z}\right) \quad \forall z \in \mathbb{C}_+,
\]
where $r = d(U_1, U_2)$, $d$ is the Euclidean distance, $P_i = m_{x_{U_i}}$ and $\nu = n/2(1/p - 1/q)$.

**Proof.** By Theorem 3.3, the family $L^{(c)}$ satisfies Davies–Gaffney estimate, and thus finite propagation speed for the corresponding wave equation with the standard Euclidean distance. We need
\[
\|\exp(-tL^{(c)})\|_{2\to q} \leq Ct^{-n/2(1/2-1/q)} \quad \forall t \in \mathbb{R}_+,
\]
for all $q$ such that $2 \leq q < p_c$. To this purpose, first note that
\[
L^{(c)} \geq \xi \Delta,
\]
where $\xi = 1 - (c/(n-2)^2/4) > 0$. Hence
\[
\|[L^{(c)}]^{-1/2}\|_{2\to q_0} \leq C\|\Delta^{-1/2}\|_{2\to q_0} < \infty
\]
where \((1/2) - (1/q_0) = 1/n\). By the proof of [17, Théorème 1], estimate (4.43) is valid for \(q = q_0\). Note that \(q_0 < p_c\). Now, by an easy adaptation of the extrapolation lemma [17, Lemme 1], estimate (4.43) holds for all \(q\) such that \(\sup \|\exp(-tL^{(c)})\|_{q \rightarrow q} < \infty\), and therefore for all \(2 \leq q < p_c\). This yields (4.43). Moreover,
\[
\|\exp\left(-(t + is)L^{(c)}\right)\|_{p \rightarrow q} \leq \|\exp(-tL^{(c)}/2)\|_{2 \rightarrow q}\|\exp(-tL^{(c)}/2)\|_{p \rightarrow 2},
\]
and so
\[
\|\exp(-zL^{(c)})\|_{p \rightarrow q} \leq C(Re\, z)^{n/2(1/q - 1/p)}
\]
for all \(z \in \mathbb{C}_+\) and all \(p, q\) such that \(p_c' < p \leq q < p_c\).

Hence for \(p, q\) such that \(p_c' < p \leq q < p_c\), the family \(L^{(c)}\) satisfies all assumptions of Theorem 4.15 with \(W_1(x, t) = Ct^{n/2(1/2 - 1/q)}\) and \(W_2(x, t) = Ct^{n/2(1/p - 1/2)}\), \(K_1 = K_2' = 1\), \(\delta_1 = n/2 (1/2 - 1/q)\) and \(\delta_2 = n/2 (1/p - 1/2)\). Thus Theorem 4.15 yields
\[
\|P_1 \exp(-zL^{(c)})P_2\|_{p \rightarrow q} \leq C r^{-\delta_1 + \delta_2} \left|\frac{r^2}{4z}\right|^{\delta_1 + \delta_2} \exp\left(-\frac{r^2}{4z}\right)
\]
\[
= C(Re\, z)^{-\delta_1 + \delta_2} \left(\frac{r^2}{4z}\right)^{(\delta_1 + \delta_2)/2} \exp\left(-\frac{r^2}{4z}\right)
\]
for all \(z \in \mathbb{C}_{r/4}^\ast\). The estimate for \(z \notin \mathbb{C}_{r/4}^\ast\) follows directly from (4.44).

\section*{4.7. Other functional spaces}

Our approach allows us to state and prove an analog of off-diagonal bounds for other functional spaces. Suppose that \(B\) is a Banach space of functions on \(M\) and that \(L^2(M, d\mu) \cap B\) is dense in \(B\) with respect to its norm. Suppose next that \(U\) is an open subset of \(M\). We define the space \(B(U)\) as the closure of \(L^2(U, d\mu) \cap B\) in the space \(B\). Then we define \(B^\ast(U)\) as the space \(B^\ast\) with seminorm given by the formula

\[
\|f\|_{B^\ast(U)} = \sup_{\|g\|_{B(U)} \leq 1} \langle f, g \rangle,
\]

where \(\langle f, g \rangle\) is the duality pairing.

**Theorem 4.18.** Let \((M, d, \mu)\) be a metric measure space, let \(B_1\) and \(B_2\) be Banach spaces as above and let \(U_1, U_2\) be open subsets of \(M\). Set \(r = d(U_1, U_2)\). Let \(g: \mathbb{C}_+ \rightarrow \mathbb{C}\) be an analytic function which satisfies condition (2.14) for \(\gamma = r^2/4\), and let \(\{\Psi(z): z \in \mathbb{C}_+\}\) be an analytic family of bounded linear operators on \(L^2(M, d\mu)\) satisfying conditions (3.1), (3.2). Assume that

\[
\|\Psi(z)\|_{B_1 \rightarrow B_2} \leq (Re\, z)^{-D/2} \exp\left(-Reg(z)\right)\quad \forall z \in \mathbb{C}_+.
\]

Then, for all \(z \in \mathbb{C}_+\),

\[
\|\Psi(z)\|_{B_1(U_i) \rightarrow B_2(U_2)} \leq (Re\, z)^{-D/2} \left(1 + \frac{r^2}{4z}\right)^{D/2} \exp\left(1 - Reg(z) - \frac{r^2}{4z}\right).
\]

About the growth condition (2.14), the same remark given after Theorem 4.7 holds.

**Proof.** For \(f_i \in L^2(U_i, d\mu) \cap B_i, i = 1, 2\), we again consider the function \(F\) defined by the formula

\[
F(z) = \langle \Psi(z)f_2, f_1 \rangle.
\]
By assumption
\[ |F(z)| \leq (\Re z)^{-D/2} \exp(-\Re g(z)) \|f_1\|_{B_1(U_1)} \|f_2\|_{B_2(U_2)} \quad z \in \mathbb{C}_+, \]
\[ |F(z)| \leq \|f_1\|_{L^2(U_1,d\mu)} \|f_2\|_{L^2(U_2,d\mu)}, \quad z \in \mathbb{C}_+, \]
and
\[ |F(t)| \leq \exp\left(-\frac{r^2}{4t}\right) \|f_1\|_{L^2(U_1,d\mu)} \|f_2\|_{L^2(U_2,d\mu)}, \quad t > 0. \]
Therefore Proposition 2.4 yields
\[ |F(z)| \leq (\Re z)^{-D/2} \left(1 + \Re \frac{r^2}{4z}\right)^{D/2} \exp\left(-\Re g(z) - \Re \frac{r^2}{4z}\right) \|f_1\|_{B_1(U_1)} \|f_2\|_{B_2(U_2)}, \]
hence the claim. \hfill \Box

**Example 4.19.** Let $\Delta$ be the Laplace–Beltrami operator acting on a complete Riemannian manifold $M$. Assume that, for some $p \in (1, \infty)$ and some $\alpha \geq 0$,
\[ \|\exp(-z\Delta)\|_{p \to p} \leq C \left(\frac{|z|}{\Re z}\right)^\alpha \quad \forall \ z \in \mathbb{C}_+. \quad (4.46) \]
Then, for any pair $U_1, U_2$ of open subsets of $M$, one has
\[ \left(\int_{U_2} |\exp(-z\Delta)f|^p \, d\mu\right)^{1/p} \leq C \left(\frac{|z|}{\Re z}\right)^\alpha \left(1 + \Re \frac{r^2}{4z}\right)^\alpha \exp\left(-\Re \frac{r^2}{4z}\right) \|f\|_{L^p(U_1,d\mu)}^2, \]
where $r = d(U_1, U_2)$, for all $z \in \mathbb{C}_+$ and $f \in L^p(U_1,d\mu)$.

**Proof.** Note that by virtue of our assumptions the semigroup $\exp(-z\Delta)$, $z \in \mathbb{C}_+$, satisfies condition (4.45) with $B_1 = L^p(M)$, $B_2 = L^p(M)$, $D = 2\alpha$ and $|e^{g(z)}| = |z|^\alpha$. Hence Example 4.19 follows from Theorem 4.18. \hfill \Box

For the relevance of assumption (4.46), see \cite{10, 15} and Corollary 4.16 above.

We can also set $g = \lambda z$ in Theorem 4.18. For $\lambda < 0$, this allows one to treat the case where one only has small time on-diagonal upper bounds, for $\lambda > 0$, this allows one, in case there is a spectral gap in the on-diagonal bounds, to keep track of it in the off-diagonal ones (see \cite{51} for more in this direction). Such modification can be made in all our previous statements leading from on-diagonal bounds to off-diagonal bounds. We leave the details to the reader.

### 4.8. Possible further generalizations

The technique presented above is very flexible. For instance, in the statement and the proof of Theorem 4.15 and many other results, we do not have to assume that the operators $\Psi(z)$ are linear. We think that it should be possible to find non-linear examples where the Phragmén–Lindelöf technique yields interesting results. Also, other pairs of dual norms than the $(L^2, L^2)$ norms could be considered in (3.1) and (3.2). Of course, in such cases, one would loose the connection with finite speed propagation.

### 4.9. Open question

Can one treat in a similar way the so-called sub-Gaussian estimates (see, for instance, \cite{7, 19}), which are typical of fractals, namely, can one imagine that, with the same notation as in condition (3.2),
\[ |\langle e^{-tL}f_1, f_2 \rangle| \leq \exp\left(-c \left(\frac{r^\beta}{t}\right)^{1/\beta-1}\right)\|f_1\|_2\|f_2\|_2, \]
where \( r \) is the distance between the supports of \( f_1 \) and \( f_2 \), and

\[
p_t(x, x) \leq \frac{C}{V(x, t^{eta/2})}
\]

imply

\[
p_t(x, y) \leq \frac{C'}{V(x, t^{eta/2})} \exp \left( -c' \left( \frac{d^2(x, y)}{t} \right)^{1/((\beta-1))} \right),
\]

for \( \beta > 2 \).

Acknowledgements. The first author would like to thank several institutions where he could find the necessary peace of mind to work on this, in particular, Macquarie University, Sydney, the University of Cyprus, the Isaac Newton Institute, Cambridge, and respectively Xuan-Thanh Duong, Georgios Alexopoulos, and the organizers of the program on Spectral theory and partial differential equations, for giving him the opportunity to stay there. The second author would like to thank Derek Robinson for organizing his extended visit to the Australian National University, where part of this work was carried out. Both authors would like to thank Brian Davies, Alexander Grigor’yan, Alexander Teplyaev, and Hendrik Vogt, whose questions and suggestions helped to improve the manuscript.
