(Received 16 October 1991; accepted for publication 20 April 1992)

By means of some reasonable rules the operators that can represent arbitrary powers of the D'Alembertian and their corresponding Green's functions are defined. It is found which powers lead to the validity of Huygens' principle. The specially interesting case of powers that are half an odd integer in spaces of odd dimensionality, obey Huygens' principle, and can be expressed as iterated D'Alembertians of the retarded potential are discussed. Arbitrary powers of the Laplacian operator as well as their corresponding Green's functions are also discussed.

I. INTRODUCTION

The ordinary wave equation, as well as its relation to the Huygens' principle (HP), has received considerable attention, and has also been the object of some beautiful works. We would like to mention the classical book on the subject by Baker and Copson,1 and the elegant analytic continuation method of Riesz.2 It is well known that HP is valid for the usual wave equation when the number n of space-time dimensions is even, but not when it is odd.

Nowadays some physicists are not happy living in a world of only four dimensions. Furthermore, second-order wave equations are no longer mandatory for the description of the evolution of physical particles or fields. For example, in gravitational theories, terms quadratic in the curvature tensor are sometimes introduced in the Lagrangian. Then, in some approximation the iterated D'Alembertian (\(\Box^2\)) is found to operate on the field.3 There are also examples, in particular, for the bosonization in 2 + 1,4 in which the equation of motion involves the square root of the Alembertian (\(\Box^{1/2}\)).

The observations lead us to consider the general problem of constructing arbitrary powers of the Lorentz invariant differential operator \(\Box\), and then of finding, in any number of dimensions, their relation to a general HP that we are going to specify later.

In Sec. II, with the aid of some reasonable rules, we find the general form of \(\Box^n\), which, although dependent somewhat on the boundary conditions, it is almost completely specified.

In Sec. III we define the Green's functions \(G^{(n)}\) and find some of their properties.

In Sec. IV we introduce the Huygens' principle. In Sec. V we study the analytic distribution \(Q^+_1\). In Sec. VI, the relations of \(G^{(n)}\) with HP are expressed in terms of the properties found in previous paragraphs. In Sec. VII we study, in particular, the interesting and less-known case of space-time with odd dimensionality (\(n=\text{odd}\)). Finally, in Sec. VIII, we introduce and discuss arbitrary powers of the Laplacian operator and their Green's functions.

In an appendix we show how to evaluate the Fourier transform of Riesz's classical retarded Green's function.

II. DEFINITION OF $\Box^a$

We suppose that space-time has $d+1=n$ dimensions, $d$ being the number of Euclidean space dimensions.

The D'Alembertian operator is

$$\Box = \partial_0^2 - \sum_{i=1}^{d} \partial_i^2 = \partial_0^2 - \Delta. \quad (1)$$

For the operator $\Box^s$ ($s=$ positive integer) the Fourier transform will be

$$\widetilde{\Box^s} = F\{\Box^s\} = (-1)^s K_+^a + K_-^a, \quad (2)$$

where, in general,

$$K_+^a = (k_0^2 - k_i^2)^a, \quad \text{if} \quad k_0^2 > k_i^2, \quad \text{zero otherwise,} \quad (3)$$

$$K_-^a = (k_0^2 - k_i^2)^a, \quad \text{if} \quad k_0^2 < k_i^2, \quad \text{zero otherwise,} \quad (4)$$

we now define $\Box^a$ (any $\alpha$) to be such that

$$\widetilde{\Box^a} = F\{\Box^a\} = f(\alpha) K_+^a + K_-^a, \quad \text{with} \quad f(s) = (-1)^s, \quad (5)$$

and impose the condition

$$\Box^a \Box^\beta = \Box^{a+\beta}, \quad (6)$$

which is equivalent to

$$\widetilde{\Box^a} \cdot \widetilde{\Box^\beta} = \widetilde{\Box^{a+\beta}}. \quad (6')$$

But $K_+^a K_+^\beta = K_+^{a+\beta}; \ K_-^a K_-^\beta = K_-^{a+\beta};$ and $K_+^a K_-^\beta = 0.$

For (6') to hold we must impose

$$f(\alpha) f(\beta) = f(\alpha + \beta). \ : \ f(\alpha) = e^{i\epsilon \alpha}. \quad (7)$$

And, due to (5), we must have

$$f(\alpha) = e^{i\epsilon \alpha}, \quad (8)$$

where $\epsilon$ is $+1$ or $-1.$

It is now easy to see that there are essentially four Lorentz-invariant solutions for $\Box^a,$ namely,

$$\widetilde{\Box^a} = e^{\pm i\alpha} K_+^a + K_-^a, \quad (9)$$

where in (8) $sgk_0$ is Lorentz invariant as $K_+^a$ is zero outside the light one [cf. (3)].

If we compare (7) with the definition for $(K + i0)^a$ given in Ref. 5, we find that

$$\widetilde{\Box^a} = e^{\pm i\alpha} (K_+^a + e^{\pi i\alpha} K_-^a) = e^{\pm i\alpha} (K + i0)^a, \quad (10)$$
so that $\square_\pm^\alpha$ is the causal D'Alembertian already discussed in Ref. 6. From (7) and (8) is easy to see that we have the relations

$$\square_+^\alpha = \theta(k_0) \square_R^\alpha + \theta(-k_0) \square_A^\alpha,$$

$$\square_-^\alpha = \theta(k_0) \square_A^\alpha + \theta(-k_0) \square_R^\alpha,$$

$\theta(x)$ being Heaviside's step function.

The operators $\square_\pm^\alpha$ are then not independent of $\square_R^\alpha$. They can be constructed by taking the positive frequency part of $\square_R^\alpha$ (resp., $\square_A^\alpha$) and the negative frequency part of $\square_A^\alpha$ (resp., $\square_R^\alpha$).

For the explicit form of $\square_\pm^\alpha$, we take the anti-Fourier transform of (7) or (9), by using the results of Ref. 5,

$$\square_\pm^\alpha = \pm i e^{\pm i n(x/2)} 4^n (4^n)^{\frac{n}{2}} \frac{\Gamma(\alpha + n/2)}{\Gamma(-\alpha)} (Q \pm i0)^{-\alpha - n/2},$$

where $Q$ is the quadratic form

$$Q = \sum_{i=1}^d x_i^2 = i^2 - j^2.$$

In the Appendix we show how to evaluate the anti-Fourier transform of (8). The result is

$$\square_R^\alpha = \frac{2 \cdot 4^n Q^{-\alpha - n/2} \theta(\mp t)}{\pi^{n/2} \Gamma(1 - \alpha - n/2) \Gamma(-\alpha)},$$

This is the operator found by Riesz by a generalization of the Riemann–Liouville complex integral (cf. Ref. 2).

Note that the by taking half the sum of the retarded plus the advanced solutions (13), we obtain an operator whose Fourier transform is

$$\square_\pm = \frac{1}{2} \square_R^\alpha + \frac{1}{2} \square_A^\alpha = \frac{1}{2} \square_+^\alpha + \frac{1}{2} \square_-^\alpha = \cos \pi \alpha K_+^\alpha + K_-^\alpha,$$

which for $\alpha = s = \text{integer}$ coincides with (2) but does not satisfy (6).

We will show below that for $\alpha = s = \text{positive integer}$ (12) and (13) reduce to

$$\square_\pm^\alpha = \square_\pm^\alpha,$$

so that in a convolution $\square^\alpha$ acts effectively as a differential operator when $\alpha = s$:

$$\square^\alpha f\big|_{\alpha = s} = \square^\alpha f(x) = \square^s f(x), \quad s = \text{positive integer}.$$  

III. THE GREEN’S FUNCTION $G^{(\alpha)}$

The Green’s function for the operator $\square^\alpha$ is the fundamental solution of the equation

$$\square^\alpha f = g,$$

i.e.,

J. Math. Phys., Vol. 34, No. 2, February 1993
By taking the Fourier transform, we find
\[ \widetilde{\alpha} \cdot \widetilde{G}^{(a)} = 1, \]
so that
\[ \widetilde{G}^{(a)} = \square^{-\alpha}. \]  
(18)

We then have [cf. (7) and (8)]
\[ \widetilde{G}_\pm = e^{\pm i a x} K_\pm + K_\mp, \]  
(19)
\[ \widetilde{G}_R^A = e^{\pm i a x k_0} K_\pm + K_\mp. \]  
(20)

And, of course [cf. (12) and (13)],
\[ G^{(a)}_\pm = \pm i e^{\pm i n/2} (4\pi)^{n/2} \frac{\Gamma(n/2-a)}{\Gamma(a)} (Q_{\pm i 0})^{a-n/2}, \]  
(21)
\[ G^{(a)}_R = \frac{2 \cdot 4^{-a} Q^{a-n/2} \theta(\mp t)}{\pi^{n/2-1} \Gamma(1+a-n/2) \Gamma(a)^2}. \]  
(22)

If we take into account (10) and (11), we can write \( G^{(a)}_\pm \) in terms of \( G^{(a)}_R \) as
\[ G^{(a)}_\pm = \delta^\pm \ast G^{(a)}_R + \delta^\mp \ast G^{(a)}_A, \]  
(23)
where
\[ \delta^\pm = F(\theta(\pm k_0)). \]  
(24)

So that the \( G^{(a)}_\pm \) Green's functions propagate the positive (negative) frequencies with the retarded \( G^{(a)}_R \) Green's function and the negative (positive) frequencies with the advanced one.

For the ordinary wave equation \( (\alpha=1) \) in four dimensions \( (n=4) \), Eq. (21) gives the massless Feynman propagator in coordinate space,
\[ G^{(1)}_\pm = \pm i e^{\pm i n/2} (4\pi)^{n/2} \frac{\Gamma(n/2-1)}{\Gamma(1)} (Q_{\pm i 0})^{1-n/2}, \]  
(25)
while Eq. (22) gives the usual retarded (advanced) potential (see Sec. V):
\[ G^{(1)}_R = \frac{1}{2\pi} \delta(Q) \theta(\mp t) = \frac{\delta(r\pm t)}{4\pi r} \]  
(26)
(n=4).

The Fourier transform of (25) is given by (9) with \( \alpha = -1 \):
\[ \widetilde{G}^{(1)}_\pm = \frac{1}{K_{\mp i 0}} \]  
(27)
The Fourier transform of (26) can be found from (8) if care is taken with the poles of $K_\pm^\alpha$ at $\alpha= -1$ (see below). The result is

$$
\mathcal{F}^{-1}\{K^{\alpha}\} = \frac{1}{K + \text{sgn} k_0} \quad (n=4). 
$$

(28)

**IV. THE HUYGENS' PRINCIPLE**

The equation corresponding to the pseudodifferential operators introduced in the next paragraph are of the form

$$
\Box^\alpha f = g. 
$$

(29)

The solution $f$ can be found by using the Green's function $G^{(a)}$, defined by (17) (also see Ref. 7),

$$
f = G^{(a)} * g. 
$$

(30)

Note that (29) and (30) are dual to each other, as $G^{(a)}$ is the operator $\Box^{-\alpha}$, and (30) can be considered to be an equation for the determination of $g$, if $f$ is given.

There are several statements that can be considered to represent the principle that Huygens introduced to describe the propagation of light waves (see Ref. 1 for a discussion of this point). We are going to adopt the following statement.

The solution (30) of Eq. (29) is said to obey Huygens' principle (HP) if the Green's function $G^{(a)}$ has its support on the surface of the light cone. This HP implies that the signals generated by the source propagate with one sharp velocity, that of the light.

Due to Eq. (23), we see that the properties of $G^{(a)}$ can be deduced from those of $G^{(a)}_R$. In fact, $G^{(a)}_R$ propagates the positive frequencies of the source by means of $G^{(a)}_R$ and the negative frequencies by means of $G^{(a)}_A$. In this sense, we can say that $G^{(a)}_\pm$ obeys HP if $G^{(a)}_R$ and $G^{(a)}_A$ do so. It is then enough to examine $G^{(a)}_R$ ($G^{(a)}_A$ is similar) to find out when HP is satisfied.

From (26) we see immediately that $G^{(a)}_R$ obey HP in $n=4$, as $\delta(Q)$ has its support on the light cone $Q=0$. For $n=\text{odd}$ number, it follows from (22) for $\alpha=1$ that

$$
G^{(1)}_R \equiv Q_+^{-n/2},
$$

which is well defined and zero outside the light cone [cf. (3)], but it is different from zero everywhere inside the light cone, and so, as is well known, the solutions of the ordinary wave equation obey HP for $n=4$ ($n=\text{even}$), but do not obey HP for $n=\text{odd}$.

In the general case, we have to examine the singularities of the functions on which $G^{(a)}_R$ depends [cf. (22)]. The positions and residues of the poles, of Eulers $\Gamma$ functions, are well known. For $Q_+^A$, as an analytic function of $\lambda$, we transcribe the results found in Ref. 5.

**V. THE ANALYTIC DISTRIBUTION $Q_+^A$**

In the following it will be evident that the structure of the singularities of $Q_+^A$ determine the relation of the Green's function $G^{(a)}_R$ with HP.

We are considering only one time and $d$ space coordinate in the quadratic form $Q = r^2 - r^2$; then, according to Ref. 5, the distribution $Q_+^A$ is an analytic function of $\lambda$ for which the following occurs. (a) Here $n=\text{odd}$ has simple poles at $\lambda = -1, -2, ..., -k, ...,$ and at $\lambda = -n/2, -n/2 - 1, -1, -n/2 - 2, ..., -n/2 - k, ...$.
The residues are

$$\text{Res } Q_+^k = \frac{(-1)^{k-1} \delta^{(k-1)}(Q)}{\Gamma(k)} (k=1,2,...),$$

(31)

$$\text{Res } Q_+^k = \frac{(-1)^{k/2} \Pi_{n/2}^k \delta(x)}{4^k \Gamma(k+1) \Gamma(n/2+k)} (k=0,1,2,...).$$

(32)

(b) Here $n=\text{even}$ has simple poles at $\lambda = -1, -2, -2-n/2, 1-n/2$ and double poles at $\lambda = -n/2, -n/2-1, ..., -n/2-k, ...$

$$\text{Res } Q_+^k = \frac{(-1)^{k-1}}{\Gamma(k)} \delta^{(k-1)}(Q) (k=1,2,..., n/2-1).$$

(33)

Near $\lambda = -n/2$, $k$, the double poles have the form

$$Q_+^k = \frac{(-1)^{k/2} \Pi_{n/2}^k \delta(x)}{4^k \Gamma(k+1) \Gamma(n/2+k)} (\lambda + n/2 + k)^4 + \cdots (k=0,1,2,...).$$

(34)

We now observe that $Q_+^k$ has the types of singularities that are present in the product $\Gamma(1+\lambda) \Gamma(\lambda+n/2)$. In fact, when $n=\text{odd}$, this product has simple poles at $\lambda = -k$ ($k$ = positive integer), and at $\lambda = -n/2-k$ ($k$ = positive integer or zero), just as in (a). Further, when $n=\text{even}$ (as in (b)), the product presents simple poles for $\lambda = -k$ ($0 < k < n/2$), and double poles for $\lambda = -k$, if $k > n/2$.

For these reasons, if we divide $Q_+^k$ by that product, we obtain

$$Q'(\lambda) = \frac{Q_+^k}{\Gamma(1+\lambda) \Gamma(n/2+\lambda)},$$

(35)

and $Q'(\lambda)$ is an entire analytic function of $\lambda$.

Furthermore, $Q'(\lambda)$ has the following properties.

(a) For $n=\text{odd}$ and $\lambda = -k$ ($k$ = positive integer),

$$Q'(-k) = \frac{1}{\Gamma(n/2-k)} \delta^{(k-1)}(Q).$$

(36)

For $n=\text{odd}$ and $\lambda = -n/2-k$ ($k=0,1,2,...$),

$$Q'(\frac{n}{2}-k) = \frac{\Pi_{n/2}^{n/2-1}}{4^k} \delta^k(x).$$

(37)

(b) For $n=\text{even}$ and $\lambda = -k$ ($k=1,2,..., n/2-1$),

$$Q'(-k) = \frac{1}{\Gamma(n/2-k)} \delta^{(k-1)}(Q).$$

(38)

For $n=\text{even}$ and $\lambda = -n/2-k$ ($k=0,1,...$),

$$Q'(\frac{n}{2}-k) = \frac{\Pi_{n/2}^{n/2-1}}{4^k} \delta^k(x).$$

(39)
VI. THE $G_R^{(a)}$ THAT OBEY HP

We first observe that $\Box_R^{(a)}$ [Eq. (13)] and $G_R^{(a)}$ [Eq. (22)] can be expressed in terms of $Q'(\lambda)$ [Eq. (35)] as

$$\Box_R^{(a)} = \frac{2 \cdot 4^a}{\Gamma(-\alpha) \Gamma(1-\alpha-n/2)} \left( \frac{\theta(-t)}{\Gamma(\alpha-n/2)} \right)$$

(40)

and

$$G_R^{(a)} = \frac{2 \cdot 4^{-a}}{\Gamma(\alpha-n/2)} \left( \frac{\theta(-t)}{\Gamma(\alpha-n/2)} \right)$$

(41)

As a consequence of the properties of $Q'(\lambda)$ pointed out in Sec. V, we have that $\Box_R^{(a)}$ and, of course, $G_R^{(a)}$ are entire analytic functions of $\alpha$ (also see Ref. 7).

For any $n$ and $\alpha = -k$ ($k=0,1,2,...$), it follows from (37), (39), and (41) that

$$G_R^{(-k)} = \Box_R^{(-k)} = \delta(x)$$

(42)

where, due to the presence of the factor $\theta(-t)$, the contribution of the retarded cone is only a half the quoted value in (37) and (39).

It is now easy to see when the Green's function $G_R^{(a)}$ obeys HP. The only cases for which $Q'(\lambda)$ has its support on the light cone are those for which (36) and (38) are valid, i.e., for $\alpha = n/2 - k$.

From (41) we then obtain

$$G_R^{(n/2-k)} = \frac{2 \cdot 4^{k-n/2}}{\Gamma(n/2-k)} \left( \frac{\theta(-t)}{\Gamma(n/2-k)} \right)$$

(43)

when $n$ is even the values of $k$ are restricted to be less than $n/2$ ($k < n/2$), but for $n$ odd, $k$ is an unrestricted positive integer.

For $n=4$ we have the usual retarded potential (26). Further, this kind of potential holds in any number of dimensions for $k=1$:

$$G_R^{(n/2-1)} = \frac{2 \theta(-t) \delta(Q)}{(4n)^{n/2-1} \Gamma(n/2-1)} = \frac{\delta(r+t)}{(4n)^{n/2-1} \Gamma(n/2-1)}$$

(44)

$$\Box^{n/2-1} G_R^{(n/2-1)} = \delta(x).$$

(45)

Equations (44) and (45) are true for any $n$ (even or odd).

The usual wave equation $\Box f = g$ is the only one whose solution obeys HP in any even number of dimensions ($n > 2$).

The once iterated D'Alembertian equation,

$$\Box^2 f = g,$$

does not obey HP in four dimensions, but it does satisfy that principle for $n = 6, 8, 10, ...$.

In general, for $\Box f = g$ to obey HP it is necessary that $n = 2(s+k) > 2(s+1)$ ($k=1,2,...$) [see Sec. V and (41)].
VII. THE CASE \( n = \text{odd} \)

The results found in Sec. VI, Eq. (43), do not seem to be well known for \( n = \text{odd} \), and they are interesting enough to deserve explicit mention, at least for low values of \( n \) (also see Ref. 8). For any odd \( n \) there are an infinite number of convolution operators whose Green’s function obeys HP. They are

\[
\square^{n/2-1}_R, \square^{n/2-2}_R, \ldots, \square^{n/2-k}_R, \ldots
\]  \hspace{1cm} (46)

From (36) and (40) we get

\[
\square^{n/2-k}_R = \frac{2 \cdot 4^{n/2-k}}{\Pi^{n/2-1}} \frac{\Gamma(k-n/2)}{\Gamma(1+k-n)} Q_{+}^{k-n}, \quad k > n.
\]  \hspace{1cm} (48)

For \( k < n \), we can also write

\[
\square^{n/2-k}_R = \square^{n-k-1+1-n/2}_R = \square^{n-k-1}_R \square^{-n/2}_R = \square^{n-k-1}_R G_{R}^{(n/2-1)},
\]  \hspace{1cm} (49)

where \( G_{R}^{(n/2-1)} \) is the usual retarded potential given by (44). With the aid of (49) we can compute the action of the operator \( \square^{n/2-k}_R \) on a function \( f \), as

\[
\square^{n/2-k}_R \ast f = \square^{n-k-1}_R G_{R}^{(n/2-1)} \ast f = G_{R}^{(n/2-1)} \ast \square^{n-k-1}_R f \quad (k < n).
\]  \hspace{1cm} (50)

In this way, the action of \( \square^{n/2-k}_R \) on \( f \) is represented by the retarded potential produced by \( \square^{n-k-1}_R f \).

For example, in \( n = 3 \), we have

\[
\square^{1/2}_R = \frac{2}{\pi} \theta(-t) \delta(Q),
\]  \hspace{1cm} (51)

\[
\square^{-1/2}_R = \frac{1}{\pi} \theta(-t) \delta(Q),
\]  \hspace{1cm} (52)

\[
\square^{-3/2}_R = \frac{1}{2\pi} \theta(-t) \theta(Q),
\]  \hspace{1cm} (53)

\[
\square^{-5/2}_R = \frac{1}{12\pi} \theta(-t) Q_{+}.
\]  \hspace{1cm} (54)

Also note that the operator \( \square^{+1/2}_R \) depends on \( n \):

\[
\square^{1/2}_R = \square^{-1/2}_R (-n-1/2) = \square^{(n-1)/2}_R G_{R}^{(n/2-1)},
\]  \hspace{1cm} (55)

where use has been made of (49) and \( G_{R}^{(n/2-1)} \) is proportional to \((1/r)\delta(r+t)\) for any \( n \).

The Green’s functions corresponding to the operators (46) can also be expressed in terms of the retarded potential (44):

\[
G_{R}^{(n/2-k)} = \square^{-n/2}_R \square^{-k-1}_R \square^{-n/2}_R = \square^{-k-1}_R G_{R}^{(n/2-1)}
\]  \hspace{1cm} (56)

J. Math. Phys., Vol. 34, No. 2, February 1993
[compare with (49)], so that the causal solution of
\[ \square_R^{n/2-k} * f = g, \]
is
\[ f = G_R^{(n/2-k)} * g = G_R^{(n/2-1)} * \square^{k-1} g \tag{57} \]
[compare with (50)].

**VIII. ARBITRARY POWERS OF THE LAPLACIAN**

Just as for the D'Alembertian, we can define arbitrary powers of the Laplacian operator \( \Delta \) (also see Ref. 7).

For the \( d \)-dimensional Euclidean space we define
\[ R = r^2 = \sum_{i=1}^{d} x_i^2, \tag{58} \]
\[ \kappa = k^2 = \sum_{i=1}^{d} k_i^2. \tag{59} \]

For \( s \) = positive integer,
\[ F\{ \Delta^s \} = \tilde{\Delta}^s = (-1)^s K^s. \tag{60} \]

We generalize this formula to
\[ F\{ \Delta^\alpha \} = \tilde{\Delta}^\alpha = e^{i\alpha \kappa}. \tag{61} \]

This definition satisfies
\[ \Delta^\alpha * \Delta^\beta = \Delta^{\alpha + \beta}; \quad \Delta^0 = \delta(x), \tag{62} \]
and gives for \( \Delta^\alpha \) the expression (see Ref. 5)
\[ \Delta^\alpha = \frac{e^{i\alpha \kappa} \Gamma(\alpha+d/2)}{\Pi^{d/2} \Gamma(-\alpha)} R^{\alpha-d/2}. \tag{63} \]

The Green's function corresponding to \( \Delta^\alpha \) is
\[ \Delta^\alpha * G^{(\alpha)} = \delta(x) \cdot G^{(\alpha)} = \Delta^{-\alpha}, \tag{64} \]
\[ G^{(\alpha)} = \frac{e^{-i\alpha \kappa} \Gamma(d/2-\alpha)}{4\alpha \Pi^{d/2} \Gamma(\alpha)} R^{\alpha-d/2}. \tag{65} \]

According to Ref. 5, the distribution \( R^\lambda \) has simple poles for \( \lambda = -s - d/2 \) \( (s=0,1,2,...) \) with residues
\[ \text{Res}_{\lambda = -s - d/2} R^\lambda = \frac{\Pi^{d/2} \Delta^\delta(x)}{4\Gamma(s+1) \Gamma(s+d/2)}, \tag{66} \]
so that, from (63) and (66), we obtain
\[ \Delta^s f = \Delta \delta(x) \ast f = \Delta^s f \quad (s=0,1,2,...). \]  

(67)

In expression (65), the poles of \( R^{a-d/2} \) are compensated or neutralized by the poles of \( \Gamma(\alpha) \).

However, the Green's function \( G^{(a)} \) has simple poles for \( \alpha = d/2 + s \quad (s=0,1,2,...) \), which are due to the presence of \( \Gamma(d/2-a) \). The residues of \( G^{(a)} \) at these poles are proportional to \( R' \) (a polynomial in \( x_i^2 \)), and they are solutions of the homogeneous equation

\[ \Delta^{d/2+s} R^s = 0. \]  

(68)

This is trivial for \( d=\text{even} \), but it is also true for \( d=\text{odd} \), as can be proved by computing \( R^{-s-d} \ast R^s \) (see Ref. 5, p. 361).

For this reason we can drop the poles of \( G^{(a)} \) and define, for \( \alpha = d/2 + s \),

\[ G^{d/2+s} = Pf \left. \frac{d}{d\alpha} \left[ \left( \alpha - \frac{d}{2} - s \right) G^{(a)} \right] \right|_{\alpha = d/2 + s}, \]  

(69)

\[ G^{d/2+s} = \frac{\exp(-i\pi(d/2)) R^s \ln R}{4^d s! \pi^{d/2} \Gamma(s+1) \Gamma(s+d/s)} \quad (s=0,1,2,...), \]  

(70)

where we have dropped terms proportional to \( R^s \) (residues).

In particular, for \( d=2 \), and \( s=0 \) we have the well-known logarithmic potential:

\[ \Delta G^{(1)} = \delta, \quad G^{(1)} = -\frac{\ln R}{4\pi}. \]  

(71)

As a matter of fact, the logarithmic potential is the Green's function corresponding to the operator \( \Delta^{d/2} \) in any number of dimensions:

\[ \Delta^{d/2} \ln R \approx \delta(x). \]

In four dimensions, for example (\( d=4 \)), the iterated Laplacian has a logarithmic potential as a fundamental solution,

\[ \Delta \Delta G^{(2)} = \delta(x), \quad G^{(2)} = \frac{\ln R}{16\pi} \quad (d=4). \]  

(72)

We may ask, in general, which is the operator that has a potential of the form \( R^\beta \) in a \( d \)-dimensional Euclidean space. The answer is given by (63) and (65) (see Ref. 7).

For the Green's function to be proportional to \( R^\beta \), we must have \( \alpha - d/2 = \beta \), so that the operator is

\[ \Delta^{\beta+d/2} = \frac{\exp(i\pi(\beta+d/2)) 4^{\beta+d/2} \Gamma(\beta+d/2)}{\pi^{d/2} \Gamma(-\beta-d/2)} R^{-\beta-d/2} \]  

(73)

and

\[ G^{(\beta+d/2)} = \frac{\exp(-i\pi(\beta+d/2)) \Gamma(-\beta)}{4^{\beta+d/2} \pi^{d/2} \Gamma(\beta+d/2)} R^\beta. \]  

(74)

The logarithmic potential corresponds to \( \beta=0 \).

For the Newtonian potential \( r^{-1} = R^{-1/2} \), \( \beta = -\frac{1}{2} \) and (73) and (74) give
C. G. Bollini and J. J. Giambiagi: Arbitrary powers of D'Alembertians

\[
\Delta^{(d-1)/2} = \frac{e^{i\pi[(d-1)/2]}}{\Pi^{d/2}G((1-d)/2)} R^{1/2-d},
\]

(75)

\[
G^{(d-1)/2} = \frac{e^{-i\pi[(d-1)/2]}}{4^{(d-1)/2}\Pi^{(d-1)/2}G((d-1)/2)} R.
\]

(76)

For odd-dimensional spaces, (75) is just the Laplacian iterated \((d-1)/2\) times. In \(d=3\) it is the usual Laplacian \(\Delta\). In \(d=5\) it is \(\Delta^2 = \Delta\Delta\), etc.

For even-dimensional spaces (70) gives an exponent that is half an odd integer.

APPENDIX:

To evaluate the Fourier transform of \(G^{(d)}_R\) [Eq. (22)], we start with

\[
F\{Q_+^d \theta(-t)\} = \int d^{n-1}x e^{ik \cdot r} \int_{-\infty}^{-r} dt (t^2-r^2)^{1/2} e^{-ik_0 t},
\]

(A1)

and use the table of integral transforms\(^9\) to write

\[
\int_{-\infty}^{-r} dt (t^2-r^2)^{1/2} e^{-ik_0 t} = \frac{\Pi^{1/2}2^{1/2} \Gamma(1+\lambda) r^{\lambda+1/2}}{\sin \pi(\lambda+1/2)} \left\{e^{i\pi k_0(\lambda+1/2)} J_{\lambda-1/2}(|k_0| r) - J_{\lambda+1/2}(|k_0| r)\right\}.
\]

(A2)

We must also take into account that the angular integral in (A1) gives

\[
\int d\Omega e^{ik r \cos \theta} = \frac{2\Pi^{(n-1)/2}}{(\pi k/2)^{(n-3)/2}} J_{(n-3)/2}(kr).
\]

(A3)

We now need integrals of the form

\[
\int_0^\infty dr r^{n/2+\lambda} J_{(n-3)/2}(kr) J_{\pm(\lambda+1/2)}(|k_0| r),
\]

(A4)

which are found in a table of integrals (Ref. 10, p. 692).

Replacing now in (A1), we obtain

\[
F\{Q_+^d \theta(-t)\} = \frac{2^{2+\lambda} \pi^{n-1} \Gamma(n/2+\lambda) \Gamma(\lambda+1) \Pi^{n-1}}{\sin \pi(\lambda+1/2)} \left\{e^{i\pi(\lambda+1/2)sgk_0 K_{-}^{\lambda-n/2} \sin \left(\frac{n}{2}+\lambda\right) - K_{+}^{\lambda-n/2} \sin \Pi(n-1)/2 + K_{-}^{\lambda-n/2} \sin \Pi\left(\lambda+\frac{1}{2}\right)}\right\}.
\]

(A5)

Now we write

\[
\sin \left(\lambda+\frac{n}{2}\right) = \sin \left(\frac{n-1}{2}\right) \cos \left(\lambda+\frac{1}{2}\right) + \sin \left(\lambda+\frac{1}{2}\right) \cos \left(\frac{n-1}{2}\right),
\]

\[
\cos (\lambda+\frac{1}{2}) = e^{-i(\lambda+1/2)sgk_0 + isgk_0 \sin (\lambda+\frac{1}{2})},
\]

and using these equalities in (A5),
\[ F\{\Omega_+^\lambda \theta(-t)\} = 2^{2\lambda} \pi^{-\frac{n}{2}} \Gamma\left(\frac{n}{2} + \lambda\right) \Gamma(\lambda + 1) \]
\[ \times \left\{\text{e}^{i\pi(\lambda + n/2)} sgk_0 K_+^{-\lambda - n/2} + K_-^{-\lambda - n/2}\right\}. \] (A6)

So we have for Rierz's Green's function [Eq. (22)]:

\[ F\{G_R^\alpha\} = e^{i\pi \alpha} gk_0 K_+^{-\alpha} + K_-^{-\alpha}. \] (A7)
