Abstract

The modularity property of the helicity formalism is used to provide amplitude expressions and stage-two spin-correlation functions which can easily be used in direct experimental searches for electro-weak symmetries and dynamics in the decay processes $t \to W^+b$, $\bar{t} \to W^-\bar{b}$. The formalism is used to describe the decay sequences $t \to W^+b \to (l^+\nu)b$, and $t \to W^+b \to (j_{dJ} j_u)b$. Helicity amplitudes for $t \to W^+b$ are obtained for the most general $J_{bt}$ current. Thereby, the most general Lorentz-invariant decay-density-matrix for $t \to W^+b \to (l^+\nu)b$, or for $t \to W^+b \to (j_{dJ} j_u)b$, is expressed in terms of eight helicity parameters and, equivalently, in terms of the structures of the $J_{bt}$ current. The parameters are physically defined in terms of partial-width-intensities for polarized-final-states in $t \to W^+b$ decay. The full angular distribution for the reactions $q\bar{q}$ and $gg \to t\bar{t} \to (W^+b)(W^-\bar{b}) \to \ldots$ can be used to measure these parameters. Since this adds on spin-correlation information from the next stage of decays in the decay sequence, such an energy-angular distribution is called a stage-two spin-correlation (S2SC) function.

\footnote{Electronic address: cnelson@bingvmb.cc.binghamton.edu}
1 INTRODUCTION

While in the standard model the violations of CP, T, and (V − A) symmetry are phenomenologically well-described by the Higgs mechanism and the CKM matrix, the depth of the dynamical understanding remains open to question. In particular, the Yukawa couplings of the fermions, and the CKM mixing angles and CP phase parameter are inserted by-hand. For this reason, and the new fermionic mass scale of $\sim 175 \text{ GeV}$ provided by the recently discovered top quark[1-3], it is important to probe for new and/or additional symmetry violations at $m_t \sim 175 \text{ GeV}$.

We use the modularity property of the helicity formalism[4] to provide amplitude expressions and stage-two spin-correlation functions which can easily be used in direct experimental searches for electro-weak symmetries and dynamics in the decay processes $t \rightarrow W^+ b$, $\bar{t} \rightarrow W^- \bar{b}$. Stage-two spin-correlation functions are also a useful technique for testing the symmetry properties and dynamics of $t\bar{t}$ pair production in both the $q\bar{q} \rightarrow t\bar{t}$ channel and the $gg \rightarrow t\bar{t}$ channel[5,6].

The reader should be aware that it is not necessary to use the helicity formalism because the observables are physically defined in terms $t \rightarrow W^+ b$ decay partial width intensities for polarized-final-states. However, the helicity formalism does provide a lucid, flexible, physical framework for connecting Lorentz-invariant couplings at the Lagrangian level with Lorentz-invariant spin-correlation functions. In practice, the helicity formalism also frequently provides insights and easy checks on the resulting formulas.

The literature on polarimetry methods and spin-correlation functions in $t$ quark physics includes Refs.[5,7,6]. Literature on methods to test for CP violation in $t$ reactions includes Refs.[5,8,9,6].

In this paper, we concentrate on the most general Lorentz-invariant decay-density-matrix $R_{\lambda_1, \lambda'_1}$ for $t \rightarrow W^+ b \rightarrow (l^+\nu)b$, or for $t \rightarrow W^+ b \rightarrow (j\bar{j}j_u)b$ where $\lambda_1, \lambda'_1 = \pm 1/2$ is the $t$ helicity.
$R_{\lambda_1, \lambda'_1}$ is expressed in terms of eight helicity parameters[6,10]. The diagonal elements are simply the angular distributions \(\frac{dN}{d(\cos \theta_t) d(\cos \theta_a) d\phi_a}\) for the polarized \(t\) decay chain, \(t \to W^+ b \to (l^+ \nu)b\), or \(t \to W^+ b \to (j_d j_u) b\).

There are eight \(t \to W^+ b\) decay parameters since there are the four \(W_L, T\) final-state combinations: The first parameter is simply \(\Gamma \equiv \Gamma_L^+ + \Gamma_T^+\), i.e. the partial width for \(t \to W^+ b\). The subscripts on the \(\Gamma\)’s denote the polarization of the final \(W^+\), either "L=longitudinal" or "T=transverse"; superscripts denote “± for sum/difference of the \(b_L\) versus \(b_R\) contributions”. In terms of the helicity amplitudes defined in Sec. 2,

\[
\Gamma_L^\pm = \left| A(0, -\frac{1}{2}) \right|^2 \pm \left| A(0, \frac{1}{2}) \right|^2
\]

\[
\Gamma_T^\pm = \left| A(-1, -\frac{1}{2}) \right|^2 \pm \left| A(1, \frac{1}{2}) \right|^2.
\] (1)

Such final-state-polarized partial widths are observables and, indeed, the equivalent helicity parameters \(\xi, \sigma, \ldots\) can be measured by various polarimetry and spin-correlation techniques.

The second helicity parameter is the \(b\) quark’s chirality parameter \(\xi \equiv \frac{1}{\Gamma}(\Gamma_L^- + \Gamma_T^-)\). Equivalently,

\[
\xi \equiv (\text{Prob } b \text{ is } b_L) - (\text{Prob } b \text{ is } b_R),
\]

\[
\xi \equiv \left| <b_L|b> \right|^2 - \left| <b_R|b> \right|^2.
\] (2)

So for \(m_b = 0\), a value \(\xi = 1\) means the coupled \(b\) quark is pure \(b_L\), i.e. \(\lambda_b = -1/2\). For \(m_b = 4.5GeV\), \(\xi = 0.9993\) for a pure \(V - A\) coupling[1].

The remaining two partial-width parameters are defined by

\[
\zeta \equiv (\Gamma_L^- - \Gamma_T^-)/\Gamma, \quad \sigma \equiv (\Gamma_L^+ - \Gamma_T^+)/\Gamma.
\] (3)

This implies for \(W^+\) polarimetry that

\[
\sigma = (\text{Prob } W^+ \text{ is } W_L) - (\text{Prob } W^+ \text{ is } W_T),
\]
is the analogue of the \(b\) quark’s chirality parameter in Eq.(2). Thus, the parameter \(\sigma\) measures the degree of polarization, “\(L\) minus \(T\)”, of the emitted \(W^+\). For a pure \((V-A)\), or \((V+A)\), coupling and the empirical masses, \(\sigma = 0.4057\). The “pre-SSB” parameter \(\zeta = 0.4063\) characterizes the remaining odd-odd mixture of the \(b\) and \(W^+\) spin-polarizations.

To describe the interference between the \(W_L\) and \(W_R\) amplitudes, we define the four normalized parameters,

\[
\begin{align*}
\omega &\equiv I^-_R / \Gamma, \quad \eta \equiv I^+_R / \Gamma \\
\omega' &\equiv I^-_L / \Gamma, \quad \eta' \equiv I^+_L / \Gamma
\end{align*}
\]

The associated \(W_L - W_T\) interference intensities are

\[
I^\pm_R = |A(0,-\frac{1}{2})| |A(-1,-\frac{1}{2})| \cos \beta_a \\
\pm |A(0,\frac{1}{2})| |A(1,\frac{1}{2})| \cos \beta^R_a \\
I^\pm_L = |A(0,-\frac{1}{2})| |A(-1,-\frac{1}{2})| \sin \beta_a \\
\pm |A(0,\frac{1}{2})| |A(1,\frac{1}{2})| \sin \beta^R_a
\]

Here, \(\beta_a \equiv \phi^{-1} - \phi^0\), and \(\beta^R_a \equiv \phi^1 - \phi^{0R}\) are the measurable phase differences of of the associated helicity amplitudes \(A(\lambda_{W^+}, \lambda_b) = |A| \exp \imath \phi\) in the standard helicity amplitude phase convention[4]. For the empirical masses, \(\omega = 0.4566\) and \(\eta = 0.4568\) are also unequal since \(m_b = 4.5 GeV\). If unlike in the SM \(\beta^R_a \neq 0\), then from Eq.(5) there are the inequalities \(\omega' \neq \eta'\) and \(\omega \neq \eta\), but both of these inequalities will be insignificant versus anticipated empirical precisions unless both \(b_R\) amplitudes, \(\lambda_{W^+} = 0, 1\), are unexpectedly enhanced.

If one factors out “\(W\)-polarimetry factors”, see below, via \(\sigma = S_W \tilde{\sigma}, \omega = R_W \tilde{\omega}, \ldots\) the parameters all equal one or zero for a pure \((V - A)\) coupling and \(m_b = 0\) ( \(\omega' = \eta' = 0\) ).

**Important Remarks:**

(1) The analytic forms of “\(\xi, \sigma, \zeta, \ldots\)” are very distinct for different unique Lorentz couplings,
see Table 1. This is also true for the partial-width-intensities for polarized-final-states, see Table 2. This is indicative of the analyzing power of stage-two spin-correlation techniques for analyzing \( t \to W^+b \) decay. Both the real and the imaginary parts of the associated helicity amplitudes can be directly measured.

(2) Primed parameters \( \omega' \neq 0 \) and/or \( \eta' \neq 0 \) \( \implies \bar{T}_{FS} \) is violated. \( \bar{T}_{FS} \) invariance will be violated when either there is a violation of canonical \( T \) invariance or when there are absorptive final-state interactions.

(3) Barred parameters \( \bar{\xi}, \bar{\zeta}, \ldots \) have the analogous definitions for the \( CP \) conjugate process, \( \bar{t} \to W^-\bar{b} \). Therefore, any \( \bar{\xi} \neq \xi, \bar{\zeta} \neq \zeta, \ldots \implies \text{CP is violated.} \) That is, “slashed parameters” \( \xi \equiv \xi - \bar{\xi}, \ldots \) could be introduced to characterize and quantify the degree of CP violation. This should be regarded as a test for the presence of a non-CKM-type CP violation because, normally, a CKM-phase will contribute equally at tree level to both the \( t \to W^+b_L \) decay amplitudes and so a CKM-phase will cancel out in the ratio of their moduli and in their relative phase. There are four tests for non-CKM-type CP violation[6,11].

(4). These helicity parameters appear in the general angular distributions for the polarized \( t \to W^+b \to (l^+\nu)b \) decay chain, and for \( t \to W^+b \to (j_d j_u)b \). Such formulas for the associated “stage-two spin-correlation” (S2SC) functions in terms of these eight helicity parameters are derived below in Sec. 5.

(5) In the presence of additional Lorentz structures, “\( W \)-polarimetry factors” \( S_W = 0.4068 \) and \( R_W = 0.4567 \) naturally appear[5,10] because of the referencing of “new physics” to the (\( V-A \)) structure of the SM. These important factors are

\[
S_W = 
\frac{1 - 2 \frac{m_t^2}{m_W^2}}{1 + 2 \frac{m_t^2}{m_W^2}}
\]
and

\[ \mathcal{R}_W = \frac{\sqrt{2} \frac{m_W}{m_r}}{1 + 2 \frac{m_W^2}{m_r^2}} \]  

(7)

We have introduced \( \mathcal{S}_W \) and \( \mathcal{R}_W \) because we are analyzing versus a reference \( J_{bt} \) theory consisting of “a mixture of only \( V \) and \( A \) couplings with \( m_b = 0 \)”.

For the third generation of quarks and leptons, this is the situation in the SM before the Higgs mechanism is invoked. We refer to this limit as the “pre-SSB” case. In this case, these W-polarimetry factors have a simple physical interpretation: for \( t \rightarrow W_{L,T}^+ b \) the factor

\[ \mathcal{S}_W = (\text{Prob } W_L) - (\text{Prob } W_T), \]

and the factor

\[ \mathcal{R}_W = \text{the “geometric mean of these probabilities” } = \sqrt{(\text{Prob } W_L)(\text{Prob } W_T)}. \]

These factors are not independent since \((\mathcal{S}_W)^2 + 4(\mathcal{R}_W)^2 = 1 \). [ If experiments for the lighter quarks and leptons had suggested instead a different dominant Lorentz-structure than \( V - A \), say \( “f_M + f_E” \), then per Table 1 we would have replaced \( \mathcal{S}_W \) everywhere by \(( -2 + \frac{w^2}{\tau^2} )/(2 + \frac{w^2}{\tau^2} )\), etc. ].

In the “pre-SSB” case, each of the eight helicity parameters also has a simple probabilistic significance for they are each directly proportional to \( \Gamma, \xi, \mathcal{S}_W, \) or \( \mathcal{R}_W \): \( \sigma \rightarrow \mathcal{S}_W, \zeta \rightarrow \mathcal{S}_W \xi, \omega \rightarrow \mathcal{R}_W \xi, \eta \rightarrow \mathcal{R}_W. \) Therefore, precision measurements with \( \xi \) and \( \zeta \) distinct, and with \( \xi \) and \( \omega \) distinct, \textbf{will be two useful probes} of the dynamics of EW spontaneous symmetry breaking, see Eqs.(26-27) in Ref. [6]. Some systematic effects will cancel by considering the ratios, \( \zeta/\xi \) versus \( \mathcal{R}_W \), and \( \omega/\xi \) versus \( \mathcal{S}_W \).

Note in this reference theory \( \xi = (|g_L|^2 - |g_R|^2)/(|g_L|^2 + |g_R|^2) \). In units of Sec. 3, \( \Gamma = \frac{g_w}{\sin^2 \theta_W}(|g_L|^2 + |g_R|^2)|V_{tb}|^2(m_t^2/m_w^2 + 1 - 2m_w^2/m_t^2) \) where \( g_{L,R} = \frac{1}{2}(g_V \mp g_A) \), so in SM limit \( g_L = \frac{g_w}{2\sqrt{2}} = g_V = -g_A \). Note also that any \( \tilde{T}_{FS} \) violation is “masked” since \( \omega' = \eta' = 0 \) (i.e. \( \beta^a = \beta^b = 0 \)
automatically. This “V and A, $m_b = 0$” masking mechanism could be partially the cause for why $T$ violation has not been manifest in previous experiments with the lighter quarks and leptons, even if it is not suppressed in the fundamental electroweak Lagrangian.

(6) The “additional structure” due to additional Lorentz couplings in $J_{bt}$ can show up experimentally because of its interference with the $(V - A)$ part which, we assume, arises as predicted by the SM.

(7) Besides model independence, a major open issue is whether or not there is an additional chiral coupling in the $t$ quark’s charged-current. A chiral classification of additional structure is a natural phenomenological extension of the standard $SU(2)_L \times U(1)$ electroweak symmetry. The requirement of $\bar{u}(p_b) \to \bar{u}(p_b)\frac{1}{2}(1 + \gamma_5)$ and/or $u(k_t) \to \frac{1}{2}(1 - \gamma_5)u(k_t)$ invariance of the vector and axial current matrix elements $\langle b|v^\mu(0)|t\rangle$ and $\langle b|a^\mu(0)|t\rangle$, allows only $g_L, g_{S+P}, g_{S-P}, g_{+} = f_M + f_E$, and $\bar{g}_+ = T^+ + T_5^+$ couplings. From this $SU(2)_L$ perspective, the relevant experimental question is what are the best limits on such additional couplings? Similarly, $\bar{u}(p_b) \to \bar{u}(p_b)\frac{1}{2}(1 - \gamma_5)$ and/or $u(k_t) \to \frac{1}{2}(1 + \gamma_5)u(k_t)$ invariance selects the complimentary set of $g_R, g_{S-P}, g_{S-P}, g_{-} = f_M - f_E$, and $\bar{g}_- = T^- - T_5^+$ couplings. The absence of $SU(2)_R$ couplings is simply built into the standard model; it is not predicted by it. So in the near future, it will be important to ascertain the limits on such $SU(2)_R$ couplings in $t$ quark physics.

(8) In a separate paper [3], it has been reported that at the Tevatron, percent level statistical uncertainties are typical for measurements of the helicity parameters $\xi, \zeta, \sigma, \omega, \eta$. At the LHC, several mill level uncertainties are typical. These are also the sensitivity levels found for measurement of the polarized-partial-widths, $\Gamma_{L,T}^\pm$, and for the non-CKM-type CP violation parameter $r_a = \frac{|A(-1, -\frac{1}{2})|}{|A(0, -\frac{1}{2})|}$ versus $r_b = \frac{|B(1, -\frac{1}{2})|}{|B(0, -\frac{1}{2})|}$. From $I_4$, see Eq.(69) below, the $\eta$ parameter($\omega$ parame-
ter) can respectively best be measured at the Tevatron (LHC). However, by the use of additional variables (all of \( \tilde{\theta}_1, \tilde{\phi}_1, \tilde{\theta}_2, \tilde{\phi}_2 \) as in Eq.(66) ) in the stage-two step of the decay sequences where \( W^\pm \rightarrow j_{\bar{d},d} j_{u,\bar{u}}, \) or \( l^\pm \nu, \) we expect that these sensitivities would then be comparable to that for the other helicity parameters. Inclusion of additional variables should also improve the sensitivity to the CP violation parameter \( \beta_a \) which is at 33° (Tevatron), 9.4° (LHC). In regard to effective mass-scales for new physics exhibited by additional Lorentz couplings, 50 − 70TeV effective-mass scales can be probed at the Tevatron and 110 − 750TeV scales at the LHC.

The cleanest measurement of these parameters would presumably be at a future \( e^-e^+ \) or \( \mu^-\mu^+ \) collider.

In Sec. 2, we introduce the necessary helicity formalism for describing \( t \rightarrow W^+ b \rightarrow (l^+\nu)b, \) and \( t \rightarrow W^+ b \rightarrow (j_{\bar{d}}j_{u})b. \)

In Sec. 3, we list the \( A(\lambda_{W+}, \lambda_b) \) helicity amplitudes for \( t \rightarrow W^+ b \) for the most general \( J_{bt} \) current. Next, the helicity parameters are expressed in terms of a “\((V−A)+\) additional chiral coupling” structure in the \( J_{bt} \) current. Two tables display the leading-order expressions for the helicity parameters when the various additional chiral couplings \( (g_i/2\Lambda_i) \) are small relative to the standard \( V−A \) coupling \( (g_L). \)

Sec. 4 gives the inverse formulas for extracting the contribution of the longitudinal and transverse \( W \)-bosons to the polarized- partial- widths, \( \Gamma_{L,T} \), and to the partial-width interference-intensities, \( I_{R,I} \), from measured values for the helicity parameters. Expressions are also listed for extracting the phase differences \( \beta_a \) and \( \beta_a^R \) from measured values for the helicity parameters.

Sec. 5 gives the derivation of the full S2SC function for the production decay sequence \( q\bar{q}, \) or \( gg \rightarrow t\bar{t} \rightarrow (W^+ b)(W^- \bar{b}) \rightarrow (l^+\nu b)(l^- \bar{\nu} \bar{b}) \) or \( (j\pi_{ja} b)(j_{\bar{d}}j_{\bar{u}} \pi \bar{b}). \) Two simpler S2SC are then derived.
Several figures show the the \( \cos \theta_1^t, \cos \tilde{\theta}_1 \) behaviour of the elements of the integrated, or “reduced”, composite-density-matrix \( \rho_{hh'} \). It is this behaviour, i.e. the use of \( W \) decay-polarimetry, which is responsible for the enhanced sensitivity of the S2SC function \( I_4 \) versus the energy-energy spin-correlation function \( I(E_{W^+}, E_{W^-}) \).

Sec. 6 contains some additional remarks.

2 THE HELICITY FORMALISM FOR

\[ t \rightarrow W^+b \rightarrow (l^+\nu)b, \text{ AND } t \rightarrow W^+b \rightarrow (j_d\bar{j}_u)b: \]

In the \( t \) rest frame, the matrix element for \( t \rightarrow W^+b \) is

\[
\langle \theta_1^t, \phi_1^t, \lambda_{W^+}, \lambda_b | \frac{1}{2}, \lambda_1 \rangle = D_{\lambda_1, \mu}^{(1/2)_t} (\phi_1^t, \theta_1^t, 0) A (\lambda_{W^+}, \lambda_b) \tag{8}
\]

where \( \mu = \lambda_{W^+} - \lambda_b \) and \( \lambda_1 \) is the \( t \) helicity. The final \( W^+ \) momentum is in the \( \theta_1^t, \phi_1^t \) direction, see Fig. 1. For the \( CP \)-conjugate process, \( \bar{t} \rightarrow W^-\bar{b} \), in the \( \bar{t} \) rest frame

\[
\langle \theta_2^t, \phi_2^t, \lambda_{W^-}, \lambda_b | \frac{1}{2}, \lambda_2 \rangle = D_{\lambda_2, \bar{\mu}}^{(1/2)_t} (\phi_2^t, \theta_2^t, 0) B (\lambda_{W^-}, \lambda_b) \tag{9}
\]

with \( \bar{\mu} = \lambda_{W^-} - \lambda_b \), \( \lambda_2 \) is the \( \bar{t} \) helicity. Rotational invariance forbids the other \( W^+ \) and \( W^- \) amplitudes, so there are only two, and not three amplitudes \( A(0, -1/2), A(-1, -1/2) \) for \( t \rightarrow W^+b_L \), etc. An elementary, technical point[11] is that we have set the third Euler angle equal to zero in the big D functions in Eqs.(8,9). A nonzero value of the third Euler angle would imply an (ackward) associated rotation about the final \( W^+ \) momentum direction in Fig. 2. This technical point is important in this paper because in the spin-correlation we exploit the azimuthal angular dependence of the second-stage, \( W^+ \rightarrow l^+\nu \) or for \( W^+ \rightarrow j_d\bar{j}_u \), in the decay sequences.
Fig. 2 defines the usual spherical angles $\tilde{\theta}_a$, $\tilde{\phi}_a$ which specify the $j_{d}d$ jet (or the $l^+$) momentum in the $W^+$ rest frame when the boost is from the $t$ rest frame. For the hadronic $W^+$ decay mode, we use the notation that the momentum of the charge $\frac{1}{3}e$ jet is denoted by $j_{d}$ and the momentum of the charge $\frac{2}{3}e$ jet by $j_u$. Likewise, Fig. 3 defines the $\tilde{\theta}_b$, $\tilde{\phi}_b$ which specify the $j_{d}$ jet (or the $l^-$) momentum which occurs in the $CP$-conjugate decay sequence.

As shown in Fig. 4, we use subscripts “1, 2” in place of “a, b” when the boost to these $W^\pm$ rest frames is directly from the $(t\bar{t})_{cm}$ center-of-mass frame. Physically these angles, $\tilde{\theta}_a$, $\tilde{\phi}_a$ and $\tilde{\theta}_1$, $\tilde{\phi}_1$, are simply related by a Wigner-rotation, see Eqs.(74,75) below. For the CP-conjugate mode, one only needs to change the subscripts $a \rightarrow b$, $1 \rightarrow 2$.

In the $W^+$ rest frame, the matrix element for $W^+ \rightarrow l^+\nu$ or for $W^+ \rightarrow j_{d}j_{u}$ is [12,13]

$$\langle \tilde{\theta}_a, \tilde{\phi}_a, \lambda_{l^+}, \lambda_\nu | 1, \lambda_{W^+} \rangle = D_{\lambda_{W^+},1}^{\lambda_{l^+}}(\tilde{\phi}_a, \tilde{\theta}_a, 0)c$$

(10)

since $\lambda_\nu = -\frac{1}{2}, \lambda_{l^+} = \frac{1}{2}$, respectively neglecting $\left( \frac{m_{l^+}}{m_W} \right)$ corrections, neglecting $\left( \frac{m_{\nu}}{m_W} \right)$ corrections.

The associated composite decay-density-matrix for $t \rightarrow W^+b \rightarrow (l^+\nu)b$, or for $t \rightarrow W^+b \rightarrow (j_{d}j_{u})b$, is

$$R_{\lambda_1,\lambda'_1} = \sum_{\lambda_W,\lambda'_W} \rho_{\lambda_1,\lambda'_1;\lambda_W,\lambda'_W} (t \rightarrow W^+b) \rho_{\lambda_W,\lambda'_W} (W^+ \rightarrow l^+\nu)$$

(11)

where $\lambda_W, \lambda'_W = 0, \pm 1$ with

$$\rho_{\lambda_1,\lambda'_1;\lambda_W,\lambda'_W} (t \rightarrow W^+b) = \sum_{\lambda_{\nu}=\pm1/2} D_{\lambda_{\nu},\lambda_1}^{(1/2)}(\phi_1, \theta_1, 0) D_{\lambda'_1,\lambda_{\nu}}^{(1/2)}(\phi'_1, \theta'_1, 0) A(\lambda_W, \lambda_{\nu}) A(\lambda'_W, \lambda_{\nu})^*$$

$$\rho_{\lambda_W,\lambda'_W} (W^+ \rightarrow l^+\nu) = D_{\lambda_W,1}^{\lambda_{l^+}}(\tilde{\phi}_a, \tilde{\theta}_a, 0) D_{\lambda'_W,1}^{\lambda_{l^+}}(\tilde{\phi}_a, \tilde{\theta}_a, 0) |c|^2$$
This composite decay-density-matrix can be expressed in terms of the eight helicity parameters:

\[
\mathbf{R} = \begin{pmatrix}
R_{++} & e^{i\phi_1} r_{+-} \\
-e^{-i\phi_1} r_{-+} & R_{--}
\end{pmatrix}
\]  

(12)

The diagonal elements are

\[
R_{\pm\pm} = n_a [1 \pm f_a \cos \theta_a^f] \pm (1/\sqrt{2}) \sin \theta_a^f \{ \sin 2\tilde{\theta}_a [\omega \cos \tilde{\phi}_a + \eta' \sin \tilde{\phi}_a] - 2 \sin \tilde{\theta}_a [\eta \cos \tilde{\phi}_a + \omega' \sin \tilde{\phi}_a] \}
\]  

(13)

The off-diagonal elements depend on

\[
r_{+-} = (r_{-+})^* = n_a f_a \sin \theta_a^f + \sqrt{2} \sin \tilde{\theta}_a \{ \cos \theta_a^f [\eta \cos \tilde{\phi}_a + \omega' \sin \tilde{\phi}_a] + i [\eta \sin \tilde{\phi}_a - \omega' \cos \tilde{\phi}_a] \}
\]  

\[-\frac{1}{\sqrt{2}} \sin 2\tilde{\theta}_a \{ \cos \theta_a^f [\omega \cos \tilde{\phi}_a + \eta' \sin \tilde{\phi}_a] + i [\omega \sin \tilde{\phi}_a - \eta' \cos \tilde{\phi}_a] \}
\]  

(14)

In Eqs.(13,14),

\[
n_a = \frac{1}{8} \{ 5 - \cos 2\tilde{\theta}_a - \sigma [1 + 3 \cos 2\tilde{\theta}_a] - 4 [\xi - \zeta] \cos \tilde{\theta}_a \}
\]  

\[
n_a f_a = \frac{1}{8} \{ 4 [1 - \sigma] \cos \tilde{\theta}_a - \xi [1 + 3 \cos 2\tilde{\theta}_a] + \zeta [5 - 2 \cos 2\tilde{\theta}_a] \}
\]  

(15)

or equivalently

\[
\begin{pmatrix}
n_a \\
n_a f_a
\end{pmatrix} = \sin^2 \tilde{\theta}_a \Gamma^\pm \pm \frac{1}{4} (3 + \cos 2\tilde{\theta}_a) \Gamma^\pm \mp \cos \tilde{\theta}_a \Gamma^\mp
\]  

(16)

For the CP-conjugate process \( \bar{t} \to W^{-}\bar{b} \to (l^-\bar{\nu})\bar{b} \) or \( \bar{t} \to W^{-}\bar{b} \to (j_d j_a)\bar{b} \)

\[
\bar{\mathbf{R}} = \begin{pmatrix}
\bar{R}_{++} & e^{i\phi_1} \bar{r}_{+-} \\
-e^{-i\phi_1} \bar{r}_{-+} & \bar{R}_{--}
\end{pmatrix}
\]  

(17)

\[
\bar{R}_{\pm\pm} = n_b [1 \mp f_b \cos \theta_b^f] \mp (1/\sqrt{2}) \sin \theta_b^f \{ \sin 2\tilde{\theta}_b [\omega \cos \tilde{\phi}_b - \eta' \sin \tilde{\phi}_b] - 2 \sin \tilde{\theta}_b [\eta \cos \tilde{\phi}_b - \omega' \sin \tilde{\phi}_b] \}
\]  

(18)
\[ \mathbf{\tilde{r}}_{+-} = (\mathbf{\tilde{r}}_{-+})^* \]

\[ = -\mathbf{n}_b f_b \sin \theta_2' - \sqrt{2} \sin \tilde{\theta}_b \{ \cos \theta_2' \bar{\eta} \cos \tilde{\phi}_b - \bar{\omega} \sin \tilde{\phi}_b \} + \iota \{ \bar{\eta} \sin \tilde{\phi}_b + \bar{\omega} \cos \tilde{\phi}_b \} \]

\[ + \frac{1}{\sqrt{2}} \sin 2\tilde{\theta}_b \{ \cos \theta_2' \bar{\omega} \cos \tilde{\phi}_b - \bar{\eta}' \sin \tilde{\phi}_b \} + \iota \{ \bar{\omega} \sin \tilde{\phi}_b + \bar{\eta}' \cos \tilde{\phi}_b \} \]

\[ \mathbf{n}_b = \frac{1}{8} (5 - \cos 2\tilde{\theta}_b - \bar{\sigma} [1 + 3 \cos 2\tilde{\theta}_b] - 4[\bar{\xi} - \bar{\zeta}] \cos \tilde{\theta}_b) \]  

\[ \mathbf{n}_b f_b = \frac{1}{8} (4[1 - \bar{\sigma}] \cos \tilde{\theta}_b - \bar{\xi} [1 + 3 \cos 2\tilde{\theta}_b] + \bar{\zeta} [5 - \cos 2\tilde{\theta}_b]) \]  

\[ \begin{pmatrix} \mathbf{n}_b \\ \mathbf{n}_b f_b \end{pmatrix} = \sin^2 \tilde{\theta}_b \frac{\Gamma^\pm}{\Gamma} \pm \frac{1}{4} (3 + \cos 2\tilde{\theta}_b) \frac{\Gamma^0}{\Gamma} \mp \cos \tilde{\theta}_b \frac{\Gamma^0}{\Gamma} \]  

\section{3 THE HELICITY PARAMETERS IN TERMS OF CHIRAL COUPLINGS}

For \( t \to W^+ b \), the most general Lorentz coupling is

\[ W^*_\mu \bar{u}_b (p) \Gamma^\mu \gamma_5 = u_t (k) \]  

where \( k_t = q_w + p_b \). In (22)

\[ \Gamma^\mu_V = g_V \gamma^\mu + \frac{f M}{2\Lambda} \epsilon^{\mu\nu}(k - p)_\nu + \frac{g_s}{2\Lambda} (k - p)_{\mu} \]

\[ + \frac{g_s}{2\Lambda} (k + p)_{\mu} + \frac{g_{T^+}}{2\Lambda} \epsilon^{\mu\nu}(k + p)_\nu \]

\[ \Gamma^\mu_A = g_A \gamma^\mu_5 + \frac{f_E}{2\Lambda} \epsilon^{\mu\nu}(k - p)_\nu \gamma_5 + \frac{g_p}{2\Lambda} (k - p)_{\mu} \gamma_5 \]

\[ + \frac{g_p}{2\Lambda} (k + p)_{\mu} \gamma_5 + \frac{g_{T^+}}{2\Lambda} \epsilon^{\mu\nu}(k + p)_\nu \gamma_5 \]

The parameter \( \Lambda = "\)the effective-mass scale of new physics"\).
Without additional theoretical or experimental inputs, it is not possible to select what is the “best” minimal set of couplings for analyzing the structure of the $J_{bt}$ current. There are the “equivalence theorems” that for the vector current, $S \approx V + f_M, T^+ \approx -V + S^-$, and for the axial-vector current, $P \approx -A + f_E, T^+_5 \approx A + P^-$. On the other hand, dynamical considerations such as compositeness would suggest searching for an additional tensorial $g_+ = f_M + f_E$ coupling which would preserve $\xi = 1$ but otherwise give non-$(V - A)$-values to the $t$ helicity parameters. For instance, $\sigma = \zeta \neq 0.41$ and $\eta = \omega \neq 0.46$.

The matrix elements of the divergences of these charged-currents are

\[(k - p)_\mu V^\mu = \left[ g_V (m_t - m_b) + \frac{gS^-}{2\Lambda} q^2 + \frac{gS^+}{2\Lambda} (m_t^2 - m_b^2) + \frac{gT^+}{2\Lambda} (q^2 - [m_t - m_b]^2) \right] \bar{u}_b u_t \quad (23)\]

\[(k - p)_\mu A^\mu = \left[ -g_A (m_b + m_t) + \frac{gP^-}{2\Lambda} q^2 + \frac{gP^+}{2\Lambda} (m_t^2 - m_b^2) + \frac{gT^+_5}{2\Lambda} (q^2 - [m_t + m_b]^2) \right] \bar{u}_b \gamma^5 u_t \quad (24)\]

Both the weak magnetism $\frac{f_M}{2\Lambda}$ and the weak electricity $\frac{f_E}{2\Lambda}$ terms are divergenceless. On the other hand, since $q^2 = m_w^2$, even when $m_b = m_t$ there are non-vanishing terms due to the couplings $S^-, T^+, A, P^-, T^+_5$.

The modularity and simple symmetry relations\cite{6} among the $t \to W^+ b$, $\bar{t} \to W^- \bar{b}$ amplitudes are possible because of the phase conventions that were built into the helicity formalism\cite{4}. In combining these amplitudes with results from calculations of similar amplitudes by diagramatic methods, care must be exercised to insure that the same phase conventions are being used (c.f. appendix in [11]).

The helicity amplitudes for $t \to W^+ b_{L,R}$ for both $(V \mp A)$ couplings and $m_b$ arbitrary are for $b_L$ so $\lambda_b = -\frac{1}{2}$,

\[
A \left( 0, \frac{-1}{2} \right) = g_L \frac{E_w + q_w}{m_w} \sqrt{m_t (E_b + q_w)} - g_R \frac{E_w - q_w}{m_w} \sqrt{m_t (E_b - q_w)} \quad (25)
\]
\[ A \left(-1, -\frac{1}{2}\right) = g_L \sqrt{2m_t (E_b + q_w)} - g_R \sqrt{2m_t (E_b - q_w)}. \quad (26) \]

and for \( b_R \) so \( \lambda_b = \frac{1}{2} \),

\[ A \left(0, \frac{1}{2}\right) = -g_L \frac{E_w - q_w}{m_w} \sqrt{m_t (E_b - q_w)} + g_R \frac{E_w + q_w}{m_w} \sqrt{m_t (E_b + q_w)} 
+ \lambda \nonumber \]

\[ A \left(1, \frac{1}{2}\right) = -g_L \sqrt{2m_t (E_b - q_w)} + g_R \sqrt{2m_t (E_b + q_w)} \quad (28) \]

Note that \( g_L, g_R \) denote the ‘chirality’ of the coupling and \( \lambda_b = \mp \frac{1}{2} \) denote the handedness of \( b_{L,R} \).

For \((S \pm P)\) couplings, the additional contributions are

\[ A(0, -\frac{1}{2}) = g_{S+P} \left(\frac{m_t}{2\Lambda}\right) \frac{2m_w}{m_w} \sqrt{m_t (E_b + q_w)} + g_{S-P} \left(\frac{m_t}{2\Lambda}\right) \frac{2m_w}{m_w} \sqrt{m_t (E_b - q_w)}, \quad A(-1, -\frac{1}{2}) = 0 (29) \]

\[ A(0, \frac{1}{2}) = g_{S+P} \left(\frac{m_t}{2\Lambda}\right) \frac{2m_w}{m_w} \sqrt{m_t (E_b - q_w)} + g_{S-P} \left(\frac{m_t}{2\Lambda}\right) \frac{2m_w}{m_w} \sqrt{m_t (E_b + q_w)}, \quad A(1, \frac{1}{2}) = 0 \quad (30) \]

The two types of tensorial couplings, \( g_\pm = f_M \pm f_E \) and \( \tilde{g}_\pm = g_{+T^+_tT^+_c} \), give the additional contributions

\[ A \left(0, \mp \frac{1}{2}\right) = \pm g_+ \left(\frac{m_t}{2\Lambda}\right) \nonumber \]

\[ \pm g_- \left(\frac{m_t}{2\Lambda}\right) \nonumber \]

\[ \pm \tilde{g}_+ \left(\frac{m_t}{2\Lambda}\right) \nonumber \]

\[ \pm \tilde{g}_- \left(\frac{m_t}{2\Lambda}\right) \nonumber \]

\[ A \left(\mp 1, \mp \frac{1}{2}\right) = \pm \sqrt{2} g_+ \left(\frac{m_t}{2\Lambda}\right) \nonumber \]

\[ \pm \sqrt{2} g_- \left(\frac{m_t}{2\Lambda}\right) \nonumber \]

\[ \pm \sqrt{2} \tilde{g}_+ \left(\frac{m_t}{2\Lambda}\right) \nonumber \]

\[ \pm \sqrt{2} \tilde{g}_- \left(\frac{m_t}{2\Lambda}\right) \nonumber \]
3.1 Helicity parameters’ form in terms of $g_L$ plus one “additional chiral coupling”

We first display the expected forms for the above helicity parameters for the $t \to W^+b$ decay for the case of a pure $V-A$ chiral coupling as in the SM. Next we will give the form for the case of a single chiral coupling ($g_i/2\Lambda_i$) in addition to the standard $V-A$ coupling. In this case, we first list the formula for an arbitrarily large additional contribution.

In Tables 3 and 4 we list the formulas to leading order in $g_i$ versus the standard $g_L$ coupling. Throughout this paper, we usually suppress the entry in the “i” subscript on the new-physics coupling-scale “$\Lambda_i$” when it is obvious from the context of interest.

In the case of “multi-additional” chiral contributions, the general formulas for $A(\lambda_W, \lambda_b)$ which are listed above can be substituted into the above definitions so as to derive the expression(s) for the “multi-additional” chiral contributions. The $m_b/m_w, m_b/m_t$ corrections to the following expressions can similarly be included.

Pure $V-A$ coupling:

$$\xi = \sigma/S_W = \zeta/S_W = \omega/R_W = \eta/R_W = 1$$
$$\omega' = \eta' = 0$$

(32)

$V+A$ also present:

$$\zeta/S_W = \xi \quad \omega/R_W = \xi$$
$$\sigma/S_W = 1 \quad \eta/R_W = 1$$

(33)

$$\xi = \frac{|g_L|^2-|g_R|^2}{|g_L|^2+|g_R|^2} \quad \omega' = \eta' = 0$$
\( S + P \) also present:

\[
\zeta = \sigma = \left( 1 - 2\frac{m_w^2}{m_t^2} \right) |g_L|^2 + \frac{m_t}{\Lambda} \left[ 1 - \frac{m_w^2}{m_t^2} \right] \mathcal{RE}(g^*_L g_{S+P}) \left/ (D^+) \right)
\]

\[\xi = 1 \tag{35} \]

\[
\omega = \eta = \sqrt{2\frac{m_w}{m_t}} \left( |g_L|^2 + \frac{m_t}{2\Lambda} \left[ 1 - \frac{m_w^2}{m_t^2} \right] \mathcal{RE}(g^*_L g_{S+P}) \right) / (D^+) \tag{36}
\]

\[
\omega' = \eta' = -\sqrt{2\frac{m_w}{m_t}} \left[ 1 - \frac{m_w^2}{m_t^2} \right] \mathcal{IM}(g^*_L g_{S+P}) / (D^+)
\]

where

\[
D^+ = \left( 1 + 2\frac{m_w^2}{m_t^2} \right) |g_L|^2 + \frac{m_t}{\Lambda} \left[ 1 - \frac{m_w^2}{m_t^2} \right] \mathcal{RE}(g^*_L g_{S+P}) + \left\{ \frac{m_t}{2\Lambda} \left[ 1 - \frac{m_w^2}{m_t^2} \right] \right\}^2 |g_{S+P}|^2
\]

\( S - P \) also present:

\[
\zeta, \sigma = \left( 1 - 2\frac{m_w^2}{m_t^2} \right) |g_L|^2 \mp \left\{ \frac{m_t}{2\Lambda} \left[ 1 - \left( \frac{m_w^2}{m_t^2} \right) \right] \right\}^2 |g_{S-P}|^2 \left/ (D^-) \right)
\]

\[\xi = \left( 1 + 2\frac{m_w^2}{m_t^2} \right) |g_L|^2 - \left\{ \frac{m_t}{2\Lambda} \left[ 1 - \left( \frac{m_w^2}{m_t^2} \right) \right] \right\}^2 |g_{S-P}|^2 \left/ (D^-) \right) \tag{37}
\]

\[
\omega = \eta = \sqrt{2\frac{m_w}{m_t}} |g_L|^2 / (D^-), \quad \omega' = \eta' = 0 \tag{39}
\]

where

\[
D^- = \left( 1 + 2\frac{m_w^2}{m_t^2} \right) |g_L|^2 + \left\{ \frac{m_t}{2\Lambda} \left[ 1 - \left( \frac{m_w^2}{m_t^2} \right) \right] \right\}^2 |g_{S-P}|^2
\]

\( f_M + f_E \) also present:

For this case we write the coupling constant of the sum of the weak magnetism and the weak electricity couplings as

\[ g_+ = f_M + f_E \]
In this notation,

\[
\zeta = \sigma = \left( 1 - 2 \frac{m_w^2}{m_t^2} |g_L|^2 + \frac{m_w^2}{m_t^2} \mathcal{R} \mathcal{E} (g_L^* g_+) \right) / \left( D_T^{-} \right) \tag{40}
\]

\[
\xi = 1
\]

\[
\omega = \eta = \sqrt{2 \frac{m_w}{m_t}} \left( |g_L|^2 - \frac{m_w^2}{2 \Lambda} \mathcal{R} \mathcal{E} (g_L^* g_+) + \frac{m_w^2}{4 \Lambda^2} |g_+|^2 \right) / \left( D_T^{-} \right) \tag{41}
\]

\[
\omega' = \eta' = - \frac{m_w}{\sqrt{2} \Lambda} \left[ 1 - \frac{m_w^2}{m_t^2} \right] \mathcal{I} \mathcal{M} (g_L^* g_+) / \left( D_T^{-} \right)
\]

where

\[
D_T^{-} = (1 + 2 \frac{m_w^2}{m_t^2}) |g_L|^2 - 3 \frac{m_w^2}{m_t \Lambda} \mathcal{R} \mathcal{E} (g_L^* g_+) + \frac{m_w^2}{4 \Lambda^2} (2 + \frac{m_w^2}{m_t^2}) |g_+|^2
\]

\[f_M - f_E \text{ also present :}\]

Similarly, we write the coupling constant of the difference of the weak magnetism and the weak electricity couplings as

\[g_+ = f_M - f_E\]

and so,

\[
\zeta, \sigma = \left( 1 - 2 \frac{m_w^2}{m_t^2} |g_L|^2 \pm \frac{m_w^2}{4 \Lambda^2} |g_-|^2 \right) / \left( D_T^{-} \right) \tag{42}
\]

where the upper(lower) sign on the “rhs” goes with the first(second) entry on the “lhs.” Also,

\[
\xi = \left( 1 + 2 \frac{m_w^2}{m_t^2} |g_L|^2 - 3 \frac{m_w^2}{m_t \Lambda} \mathcal{R} \mathcal{E} (g_L^* g_+) \right) / \left( D_T^{-} \right) \tag{43}
\]

\[
\omega, \eta = \sqrt{2 \frac{m_w}{m_t}} \left( |g_L|^2 \pm \frac{m_w^2}{4 \Lambda^2} |g_-|^2 \right) / \left( D_T^{-} \right), \ \omega' = \eta' = 0 \tag{44}
\]

Here

\[
D_T^{-} = (1 + 2 \frac{m_w^2}{m_t^2}) |g_L|^2 \pm 3 \frac{m_w^2}{4 \Lambda^2} |g_-|^2
\]

\[T^+ + T_5^+ \text{ also present :}\]
We let
\[ \tilde{g}_+ = g^+_{T^+T_5} \]

In this notation,
\[ \zeta = \sigma = \xi = 1 \]  \hspace{1cm} (45)

Also
\[ \omega = \eta = 1; \quad \omega' = \eta' = 0 \]  \hspace{1cm} (46)

A single additional \( \tilde{g}_+ = g^+_{T^+T_5^+} \) coupling does not change the values from that of the pure \( V - A \) coupling.

\( T^+ - T_5^+ \) also present:

We let
\[ \tilde{g}_- = g^+_{T^-T_5} \]

and so,
\[ \zeta = \xi, \quad \sigma = 1 \]  \hspace{1cm} (47)
\[ \xi = \frac{|g_L|^2 - \frac{\bar{m}_L g_\tilde{g}_-}{2\Lambda}}{|g_L|^2 + \frac{\bar{m}_L g_\tilde{g}_-}{2\Lambda}} \]  \hspace{1cm} (48)
\[ \omega = \xi, \quad \eta = 1, \quad \omega' = \eta' = 0 \]  \hspace{1cm} (49)

A single additional \( \tilde{g}_- = g^+_{T^-T_5^+} \) coupling is equivalent to a single additional \( V + A \) coupling, except for the interpretation of their respective chirality parameters.
3.2 Helicity parameters to leading-order in one

“additional chiral coupling”

In Table 3 for the $V + A$ and for the $S \mp P$ couplings, we list the “expanded forms” of the above expressions to leading-order in a single additional chiral coupling ($g_i/2\Lambda_i$) versus the standard $V - A$ coupling ($g_L$). Similarly, in Table 4 is listed the formulas for the additional tensorial couplings. The tensorial couplings include the sum and difference of the weak magnetism and electricity couplings, $g_{\pm} = f_M \pm f_E$, which involve the momentum difference $q_w = k_t - p_b$. The alternative tensorial couplings $\tilde{g}_{\pm} = g^+_{T^+T^\mp}$ instead involve $k_t + p_b$. In application[6] of $I_4$ to determine limits on a pure $IM(g_+)$, as in [6], since $RE(g_L^*g_+) = 0$, the additional terms in Table 4 going as $|g_+|^2$ can be used; for other than pure $IM(g_+)$, one should work directly from the above expressions in the text. This remark also applies for determination of limits for a pure $IM(g_{S\mp P})$ from Table 3.

Notice that, except for the following coefficients, the formulas tabulated in these two tables are short and simple. As above we usually suppress the entry in the “i” subscript on “$\Lambda_i$.” For Table 3 these coefficients are

\[
\begin{align*}
\alpha &= \frac{4m^2_{\gamma\mu}}{m_t\Lambda} \frac{1 - \frac{m^2}{m^2_t}}{1 - \frac{4m^2}{m^2_t}} \\
\delta &= \frac{m^2}{4\Lambda^2} \frac{1 - \frac{m^2}{m^2_t}}{\frac{1 - \frac{m^2}{m^2_t}}{1 + \frac{m^2}{m^2_t}}} \\
\beta &= \frac{m^2}{2\Lambda^2} \frac{1 - \frac{m^2}{m^2_t}}{\frac{1 - \frac{m^2}{m^2_t}}{1 + \frac{m^2}{m^2_t}}} \\
\epsilon &= \frac{m^2}{4\Lambda^2} \frac{1 - \frac{m^2}{m^2_t}}{\frac{1 - \frac{m^2}{m^2_t}}{1 + \frac{m^2}{m^2_t}}} \\
\gamma &= \frac{m^2}{\Lambda^2} \frac{1 - \frac{m^2}{m^2_t}}{\frac{1 - \frac{m^2}{m^2_t}}{1 + \frac{m^2}{m^2_t}}} \\
\delta &= \frac{m^2}{2\Lambda^2} \frac{1 - \frac{m^2}{m^2_t}}{\frac{1 - \frac{m^2}{m^2_t}}{1 + \frac{m^2}{m^2_t}}}
\end{align*}
\]

(50)
The additional coefficients for Table 4 are

\[ g = \frac{2m_w^2}{m_t\Lambda} \left(1 - \frac{4m_t^2}{m^2}\right) \left(1 - \frac{4m_t^2}{m^2}\right) \]
\[ l = \frac{m_t(1 + 2m_t^2 + m_b^2)}{2\Lambda(1 + 2m_t^2)} \]
\[ h = \frac{1}{2\Lambda} \left(1 - \frac{4m_t^2}{m^2}\right) \left(1 - \frac{4m_t^2}{m^2}\right) \]
\[ n = \frac{m_t^2(2 + m_b^2)}{2\Lambda^2(1 + 2m_t^2)} \]
\[ j = \frac{1}{\Lambda^2} \left(1 - \frac{4m_t^2}{m^2}\right) \left(1 - \frac{4m_t^2}{m^2}\right) \]
\[ o = \frac{m_t^2}{2\Lambda^2(1 + 2m_t^2)} \]
\[ k = \frac{1}{2\Lambda^2(1 + 2m_t^2)} \left(1 - \frac{4m_t^2}{m^2}\right) \left(1 - \frac{4m_t^2}{m^2}\right) \]
\[ u = \frac{m_t^2}{\Lambda^2} \left(1 - \frac{4m_t^2}{m^2}\right) \]

Notice that \( O(1/\Lambda) \) coefficients occur in the case of an interference with the \( g_L \) coupling, and that otherwise \( O(1/\Lambda^2) \) coefficients occur.

When the experimental precision is sensitive to effects associated with the finite width \( \sim 2.07 GeV \) of the \( W^- \) boson, then a smearing over this width and a more sophisticated treatment of these coefficients will be warranted. Numerically, for \( m_t = 175 GeV, m_w = 80.36 GeV, m_b = 4.5 GeV \) these coefficients are:

\[ a\Lambda = 141.6; b\Lambda^2 = 11,600; c\Lambda^2 = 4,890; d\Lambda = 14.05; e\Lambda^2 = 3,354; f\Lambda = 69.05; \]
\[ g\Lambda = 14.07; h\Lambda^2 = 615.4; j\Lambda^2 = 6,197; k\Lambda^2 = 6,812; l\Lambda = 183.8; n\Lambda^2 = 5,020; \]
\[ o\Lambda^2 = 1,792; u\Lambda^2 = 7,503 \]

In comparing the entries in these two tables, notice that (i) a single additional \( \tilde{g}_+ = g^{T+}_T + g^{T+}_b \) coupling does not change the values from that of the pure \( V - A \) coupling, and that (ii) a single additional \( \tilde{g}_- = g^{T-}_T - g^{T-}_b \) coupling is equivalent to a single additional \( V + A \) coupling, except for the interpretation of their respective chirality parameters. This follows as a consequence of the above 'equivalence theorems’ and the absence of contributions from the \( S^- \) and \( P^- \) couplings when the \( W^+ \) is on-shell. We have displayed this equivalence in Table 4 to emphasize that while an assumed total absence of \( \tilde{g}_\pm \) couplings in \( t \to W^+b \) decay might be supported by the weaker test
of the experimental/theoretical normalization of the decay rate ( i.e. the canonical universality test ), empirical \( V - A \) \( (V + A) \) values of the helicity parameters shown in these tables will not imply the absence of \( \tilde{g}_+ \) \( (\tilde{g}_- \) couplings.

4 TESTS FOR “NEW PHYSICS”

In context of the helicity parameters, this topic in discussed is a separate paper\[6\]. Here we include some useful formulas that were omitted in that discussion.

The contribution of the longitudinal(\(L\)) and transverse(\(T\)) \(W\)-amplitudes in the decay process is projected out by the simple formulas:

\[
I^{b_L,b_R}_{b_L} \equiv \frac{1}{2}(I^+_R \pm I^+_R) = |A(0,\mp \frac{1}{2})||A(\mp 1, \mp \frac{1}{2})| \cos \beta^{L,R} = \frac{\Gamma}{2}(\eta \pm \omega)
\]

\[
I^{b_L,b_R}_{b_T} \equiv \frac{1}{2}(I^+_T \pm I^+_T) = |A(0,\mp \frac{1}{2})||A(\mp 1, \mp \frac{1}{2})| \sin \beta^{L,R} = \frac{\Gamma}{2}(\eta' \pm \omega')
\]

\[
\Gamma^{b_L,b_R}_{b_L} \equiv \frac{1}{2}(I^-_L \pm I^-_L) = |A(0,\mp \frac{1}{2})|^2 = \frac{\Gamma}{4}(1 + \sigma \pm \xi \pm \zeta)
\]

\[
\Gamma^{b_L,b_R}_{b_T} \equiv \frac{1}{2}(I^-_T \pm I^-_T) = |A(\mp 1, \mp \frac{1}{2})|^2 = \frac{\Gamma}{4}(1 - \sigma \pm \xi \mp \zeta)
\]

In the first line, \( \beta^{L}_a = \beta_a \). Unitarity, requires the two right-triangle relations

\[
(I^{b_L}_R)^2 + (I^{b_L}_T)^2 = \Gamma^{b_L}_L \Gamma^{b_L}_T
\]

\[
(I^{b_R}_R)^2 + (I^{b_R}_T)^2 = \Gamma^{b_R}_L \Gamma^{b_R}_T.
\]

It is important to determine directly from experiment whether or the \(W_L\) and \(W_T\) partial widths are anomalous in nature versus the standard \((V - A)\) predictions. They might have distinct dynamical
differences versus the SM predictions if electroweak dynamical symmetry breaking (DSB) occurs in nature.

By unitarity and the assumption that only the minimal helicity amplitudes are needed, one can easily derive expressions for measuring the phase differences between the helicity amplitudes. In the case of both $b_L$ and $b_R$ couplings, there is

$$\cos \beta_a = \frac{t_{g_L}^{b_L}}{\sqrt{\Gamma_{gL}^{b_L} \Gamma_{gT}^{b_L}}} = \frac{2(\omega + \eta)}{\sqrt{(1+\xi)^2-(\sigma+\zeta)^2}}$$

(56)

and for the $b_R$ phase difference,

$$\cos \beta_a^R = \frac{t_{g_R}^{b_R}}{\sqrt{\Gamma_{gL}^{b_R} \Gamma_{gT}^{b_R}}} = \frac{2(\eta - \omega)}{\sqrt{(1-\xi)^2-(\sigma-\zeta)^2}}$$

(57)

Also

$$\sin \beta_a = \frac{t_{g_L}^{b_L}}{\sqrt{\Gamma_{gL}^{b_L} \Gamma_{gT}^{b_L}}} = \frac{2(\omega' + \eta')}{\sqrt{(1+\xi)^2-(\sigma+\zeta)^2}}$$

(58)

with

$$\sin \beta_a^R = \frac{t_{g_R}^{b_R}}{\sqrt{\Gamma_{gL}^{b_R} \Gamma_{gT}^{b_R}}} = \frac{2(\eta' - \omega')}{\sqrt{(1-\xi)^2-(\sigma-\zeta)^2}}$$

(59)

Measurement of $\beta_a \neq 0$ ($\beta_b \neq 0$) implies a violation of $T$ invariance in $t \to W^+b(\bar{t} \to W^-\bar{b})$ or the presence of an unexpected final-state interaction between the $b$ and $W^+$. Because of the further assumption of no-unusual-final-state-interactions, one is actually testing for $T_{FS}$ invariance. Canonical $T$ invariance relates $t \to W^+b$ and the actual time-reversed process $W^+b \to t$ which is
not directly accessible by present experiments. Equivalent to the two right-triangle relations are two expressions involving the helicity parameters:

\[(\eta \pm \omega)^2 + (\eta' \pm \omega')^2 = \frac{1}{4}[((1 \pm \xi)^2 - (\sigma \pm \zeta)^2)].\]  

(60)

Fig. 5 displays a simple test of $\tilde{T}_{FS}$ invariance using the first relation. With foreseeable experimental precisions, the second relation appears unlikely to be tested in the near future.

5 STAGE-TWO SPIN-CORRELATION FUNCTIONS

For $t\bar{t}$ production at hadron colliders, a simple consequence of the QM-factorization structure of the parton model is that there are incident parton longitudinal beams characterized by the Feynman $x_1$ and $x_2$ momentum fractions instead of the known $p$ and $\bar{p}(p)$ momenta. This momentum uncertainty must therefore be smeared over in application of the following S2SC functions and in determination of the associated sensitivities for measurement of the above helicity parameters.

5.1 The full S2SC function:

We consider the production-decay sequence

\[q\bar{q}, or gg \rightarrow t\bar{t} \rightarrow (W^+b)(W^-\bar{b})\]

\[\rightarrow (l^+\nu_b)(l^-\bar{\nu}) or (j_{\bar{d}j_u}b)(j_d\bar{\nu})\]  

(61)

The general angular distribution in the $(t\bar{t})_{cm}$ is

\[I(\Theta_B, \Phi_B; \theta_1^t, \phi_1^t, \tilde{\theta}_a, \phi_a, \theta_2^t, \phi_2^t, \tilde{\theta}_b, \phi_b) = \sum_{\lambda_1, \lambda_2; \lambda'_1, \lambda'_2} \rho_{\lambda_1\lambda_2; \lambda'_1\lambda'_2}^{prod} \rho_{\lambda_1\lambda_2; \lambda'_1\lambda'_2}^{prod}(\Theta_B, \Phi_B)\]

\[\times R_{\lambda_1\lambda'_1}(t \rightarrow W^+b \rightarrow \ldots) R_{\lambda_2\lambda'_2}(t \rightarrow W^-\bar{b} \rightarrow \ldots)\]  

(62)
where the composite decay-density-matrix $R_{\lambda_1\lambda_1'}$ for $t \to W^+b \to \ldots$ is given by Eq.(12), and that $R_{\lambda_2\lambda_2'}$ for $\bar{t} \to W^-\bar{b} \to \ldots$ is given by Eq.(17). The angles $\Theta_B, \Phi_B$ give[11,12] the direction of the incident parton beam, i.e. the $q$ momentum or the gluon’s momentum, arising from the incident $p$ in the $pp$, or $pp \to t\bar{t}X$ production process. With Eq.(62) there is an associated differential counting rate

$$dN = I(\Theta_B, \Phi_B; \ldots) d(cos \Theta_B) d\Phi_B d(cos \theta_t^1) d\phi_1^t$$

$$+ d(cos \tilde{\theta}_a) d\tilde{\phi}_a d(cos \theta_t^2) d\phi_2^t d(cos \tilde{\theta}_b) d\tilde{\phi}_b$$

where, for full phase space, the cosine of each polar angle ranges from -1 to 1, and each azimuthal angle ranges from 0 to $2\pi$.

Each term in Eq.(62) can depend on the angle between the $t$ and $\bar{t}$ decay planes

$$\phi = \phi_1^t + \phi_2^t$$

and on the angular difference

$$\Phi_R = \Phi_B - \phi_1^t$$

So, we treat $\Phi_B, \Phi_R, \phi$ as the azimuthal variables. We integrate out $\Phi_R$. The resulting full S2SC function is relatively simple:

$$I(\Theta_B, \Phi_B; \phi_1^t, \tilde{\phi}_a, \tilde{\phi}_2^t, \tilde{\phi}_b) = \sum_{h_1h_2} \rho_{h_1h_2,h_1h_2}^{\text{prod}} R_{h_1h_1} \overline{R_{h_2h_2}}$$

$$+ (\rho_{++,-}^{\text{prod}} r_{++} r_{+-} + \rho_{--,+}^{\text{prod}} r_{--} r_{+-}) \cos \phi + i(\rho_{++,-}^{\text{prod}} r_{--} r_{+-} - \rho_{--,+}^{\text{prod}} r_{++} r_{+-}) \sin \phi$$

where $\rho_{h_1h_2,h_1h_2}^{\text{prod}}(\Theta_B, \Phi_B)$ still depends on $\Theta_B, \Phi_B$ and the composite density matrix elements are given above. The $\theta_t^1$ angular dependence can be replaced by the $W^+$ energy in the the $(t\bar{t})_{cm}$ and similarly $\theta_t^2$ by the $W^-$ energy[12]. The $\sin \phi$ dependence is the well-known test for $CP$-violation in the production process[13,5].
5.2 Two simpler S2SC functions:

We next integrate out some of the variables to obtain simpler S2SC functions. First[11], we transform to the variables of Fig. 4 and then integrate out the two azimuthal angles $\tilde{\phi}_1, \tilde{\phi}_2$. This gives a five variable S2SC with respect to the final decay products:

$$I(\phi; \theta_t^1, \tilde{\theta}_1; \theta_t^2, \tilde{\theta}_2) = \sum_{h_1 h_2} \rho^\text{prod}_{h_1 h_2, h_1 h_2} R_{h_1 h_2} \overline{R_{h_2 h_2}}$$

$$+ 2 \cos \phi \mathcal{R} \mathcal{E}(\rho^\text{prod}_{+, -, +, -} - \rho^\text{prod}_{-, +, -}) - 2 \sin \phi \mathcal{L} \mathcal{M}(\rho^\text{prod}_{+, -, +, -})$$

(67)

The $\sin \phi$ term will vanish if both CP invariance holds in $(t\bar{t})$ production and $\beta_a = \beta_b = 0$ in $t$ and $\bar{t}$ decays.

Diagonal $\rho_{\pm \pm}$ and off-diagonal $\rho_{\pm \mp}$ appear here to describe the decay sequence $t \to W^+ b \to l^+ \nu b$, or $j_d j_u b$. The CP-conjugate sequences are described by $\overline{\rho_{\pm \pm}}, \overline{\rho_{\pm \mp}}$. These integrated, composite density matrix elements are defined by

$$\rho_{h_1 h_1} \equiv \frac{1}{2\pi} \int_0^{2\pi} d\phi_1 R_{h_1 h_1}/|A(0, -\frac{1}{2})|^2$$

$$\overline{\rho_{h_2 h_2}} \equiv \frac{1}{2\pi} \int_0^{2\pi} d\phi_1 \overline{R_{h_2 h_2}}/|B(0, \frac{1}{2})|^2$$

$$= \rho_{-h_2 h_2} \text{ (subscripts} 1 \to 2, a \to b)$$

$$\rho_{+-} = (\rho_{-+})^* \equiv \frac{1}{2\pi} \int_0^{2\pi} d\phi_1 r_{+-}/|A(0, -\frac{1}{2})|^2$$

$$\overline{\rho_{+-}} = (\overline{\rho_{-+}})^* \equiv \frac{1}{2\pi} \int_0^{2\pi} d\phi_1 \overline{r_{+-}}/|B(0, \frac{1}{2})|^2$$

$$= -\rho_{+-} \text{ (subscripts} 1 \to 2, a \to b, \beta_a \to \beta_b)$$

(68)

where the last lines for the CP conjugate ones shows useful CP substitution rules.

By integrating out the angle $\phi$ between the $t$ and $\bar{t}$ decay planes, a simple four-variable S2SC function is obtained.
\[ I(E_{W^+}, E_{W^-}, \tilde{\theta}_1, \tilde{\theta}_2) = \sum_{h_1, h_2} \{ \rho_{h_1h_2}^{prod} \rho_{h_1 h_1} \rho_{h_2 h_2} \} \]

\[ = \sum_i \{ \rho_{+-}(q_i \bar{q}_i \rightarrow t \bar{t})^{prod}[\rho_{++}p_{--} + \rho_{--}p_{++}] + \rho_{++}(g g \rightarrow t \bar{t})^{prod}[\rho_{++}p_{++} + \rho_{--}p_{--}] \} \]  

(69)

where the sum is over the quarks and gluons in the incident \( pp \) or \( pp \). In the second line we have assumed \( CP \) invariance in the production processes.

The simplest kinematic measurement of the above helicity parameters at the Tevatron and at the LHC would be through purely hadronic top decay modes. CDF has reported\[14\] observation of such decays. In this case the \((t\bar{t})_{cm}\) frame is accessible and the above \( I_4 \) can be used. In a separate paper\[6\] we have reported that the associated statistical sensitivities to the helicity parameters are at the percent level for measurements at the Tevatron, and at the several mill level for at the LHC. Fig. 6 shows the net \( E_{W^+}, E_{W^-} \) dependence of Eq.(69).

### 5.3 Integrated composite decay-density-matrix elements:

In (69), the composite decay-density-matrix elements are simply the decay probability for a \( t_1 \) with helicity \( \frac{h}{2} \) to decay \( t \rightarrow W^+b \) followed by \( W^+ \rightarrow j_d j_u \), or \( W^+ \rightarrow l^+\nu \) since

\[ dN/d (\cos \theta_t^l) d (\cos \tilde{\theta}_1) = \rho_{hh}(\theta_t^l, \tilde{\theta}_1) \] and for the decay of the \( \bar{t}_2 \) with helicity \( \frac{h}{2} \), \( \tilde{\rho}_{hh} = \rho_{-h,-h}(1 \rightarrow 2, addbars) \). For \( t_1 \) with helicity \( \frac{h}{2} \)

\[ \rho_{hh} = \rho_o + h \rho_c \cos \theta_t^l + h \rho_s \sin \theta_t^l \]  

(70)

where

\[ \rho_o = \frac{1}{8} \{ 6 - 2 \cos^2 \omega_1 \cos^2 \tilde{\theta}_1 - \sin^2 \omega_1 \sin^2 \tilde{\theta}_1 \]

\[ + \sigma [2 - 6 \cos^2 \omega_1 \cos^2 \tilde{\theta}_1 - 3 \sin^2 \omega_1 \sin^2 \tilde{\theta}_1] - 4(\xi - \zeta) \cos \omega_1 \cos \tilde{\theta}_1 \} \]  

(71)
\[ \rho_c = \frac{1}{8} \{ \zeta [6 - 2 \cos^2 \omega_1 \cos^2 \tilde{\theta}_1 - \sin^2 \omega_1 \sin^2 \tilde{\theta}_1] \\
+ \xi [2 - 6 \cos^2 \omega_1 \cos^2 \tilde{\theta}_1 - 3 \sin^2 \omega_1 \sin^2 \tilde{\theta}_1] + 4(1 - \sigma) \cos \omega_1 \cos \tilde{\theta}_1 \} \] (72)

\[ \rho_s = \frac{1}{\sqrt{2}} \{ \frac{1}{2} \omega \sin 2\omega_1 [\sin^2 \tilde{\theta}_1 - 2 \cos^2 \tilde{\theta}_1] + 2\eta \sin \omega_1 \cos \tilde{\theta}_1 \} \] (73)

with the Wigner rotation angle \( \omega_1 = \omega_1(E_{W^+}) \). The rotation by \( \omega_1 \) is about the implicit \( y_a \) axis in Fig. 2. It is given by[11]

\[ \sin \omega_1 = m_W \beta \gamma \sin \theta^t_1/p_1 \] (74)

\[ \cos \omega_1 = \frac{E_{cm}(m_t^2 - m_W^2 + [m_t^2 + m_W^2]\beta \cos \theta^t_1)}{4m_t^2p_1} \] (75)

where \( p_1 \) = the magnitude of the \( W^+ \) momentum in the \( (t\bar{t})_{cm} \) frame and \( \gamma, \beta \) describe the boost from the \( (t\bar{t})_{cm} \) frame to the \( t_1 \) rest frame \( [\gamma = E_{cm}/(2m_t)] \) with \( E_{cm} = \) total energy of \( t\bar{t} \), in \( (t\bar{t})_{cm} \).

Note that the \( \rho_s \) term depends only on the \( W_L - W_T \) interference intensities, whereas the \( \rho_o \) and \( \rho_c \) terms only depend on the polarized- partial-widths, specifically

\[ \rho_{o,c} = \frac{1}{2} [2 - 2 \cos^2 \omega_1 \cos^2 \tilde{\theta}_1 - \sin^2 \omega_1 \sin^2 \tilde{\theta}_1] \tilde{\Gamma}_{\pm} / \Gamma \\
\pm \frac{1}{4} [2 + 2 \cos^2 \omega_1 \cos^2 \tilde{\theta}_1 + \sin^2 \omega_1 \sin^2 \tilde{\theta}_1] \tilde{\Gamma}_{\mp} / \Gamma \mp \cos \omega_1 \cos \tilde{\theta}_1 \tilde{\Gamma}_{\mp} / \Gamma \] (76)

with \( \tilde{\rho}_{o,c} = \rho_{o,c} \) ( \( 1 \rightarrow 2, addbars \)).

For the off-diagonal elements, the analogous expression is

\[ \rho_{+-} = \rho_c \sin \theta^t_1 - \sqrt{2}(\eta \cos \theta^t_1 - i\omega') \sin \omega_1 \cos \tilde{\theta}_1 \] (77)

\[ + \frac{1}{2\sqrt{2}}(\omega \cos \theta^t_1 - i\eta') \sin 2\omega_1 [2 \cos^2 \tilde{\theta}_1 - \sin^2 \tilde{\theta}_1] \]

Figures 7-14 show the \( \cos \theta^t_1, \cos \tilde{\theta}_1 \) behaviour of the elements of these integrated, or “reduced”, composite-density-matrix \( \rho_{hh'} \) assuming the \( (V - A) \) values of Table 1 for the helicity parameters. These figures also show the dependence as the total center-of-mass energy \( E_{cm} \) is changed. Fig. 7
is for $\rho_{++}$ and $E_{cm} = 380 \text{ GeV}$. The next one, Fig. 8, is for $E_{cm} = 450 \text{ GeV}$. This dependence on $\cos \theta_1^t, \cos \tilde{\theta}_1$, i.e. the use of W decay-polarimetry, is the reason for the greater sensitivity of the S2SC function, $I_4$, than the simpler energy-energy spin- correlation function $I(E_{W+}, E_{W-})$, see Sec. 6. Figs. 9-10 show the behaviour of $\rho_{-\cdot}$. The behaviours of the real and imaginary parts of the off-diagonal elements $\rho_{+-}$ are shown in Figs. 11-14. Note that to display the imaginary part with an arbitrarily fixed overall normalization, we have set $\omega' = \eta' = 1$ in Eq.(77) since in the SM the relative phase $\beta^R_a = 0$.

If the $(V - A)$ values for the helicity parameters are empirically found to be only approximately correct, then the details of the dependence of $\rho_{hh'}$ on $\cos \theta_1^t, \cos \tilde{\theta}_1$, and $E_{cm}$ will differ but, nevertheless, the analyzating power of $\rho_{hh'}$ and of $R$ of Eq.(12) should remain large at both the Tevatron and the LHC.

### 5.4 Production density matrix elements:

The production density matrix elements for $gg \to t\bar{t}$ are calculated by the methods in [15,12]. In the usual helicity phase conventions, we obtain

$$
\rho_{++}(gg \to t\bar{t}) = \rho_{++} = \rho_{--} = \rho_{-\cdot-}\tag{78}
$$

$$
\rho_{+-}(gg \to t\bar{t}) = \rho_{+-} = \rho_{-\cdot+} = \rho_{+-+}\tag{79}
$$

where $E_t$ is the energy of the produced $t$ quark with momentum of magnitude $p_t$ at angle $\theta_t$ in the $(t\bar{t})_{cm}$ frame.

The amplitudes for $q\bar{q} \to t\bar{t}$ in the helicity phase convention are easily obtained from those in
Ref. [12]. The associated production density matrix elements are

$$\rho_{++}(q\bar{q} \rightarrow t\bar{t}) = \rho_{++} = \rho_{--}$$

$$= \frac{m_t^2}{2E_t} \sin^2 \theta_t$$

$$\rho_{+-}(q\bar{q} \rightarrow t\bar{t}) = \rho_{+-} = \rho_{-+}$$

$$= \frac{1}{3}(1 + \cos^2 \theta_t)$$

(80)

The normalization in these equations correspond to the hard parton, differential cross-sections

$$\frac{d\hat{\sigma}}{dt} = \frac{\alpha_s^2}{s^2} (\rho_{++} + \rho_{--} + \rho_{+-} + \rho_{-+})$$

(82)

6 ADDITIONAL REMARKS

The simpler stage-one spin-correlation function $I(E_{W+}, E_{W-})$ of Ref. [5] directly follows from Eq.(69) by integrating out $\tilde{\theta}_1$ and $\tilde{\theta}_2$

$$I(E_{W+}, E_{W-}) = \sum_i \{ \rho_{+-}(q\bar{q} \rightarrow t\bar{t})^{prod}[\rho_{++} + \rho_{--}] + \rho_{++}(gg \rightarrow t\bar{t})^{prod}[\rho_{++} + \rho_{--}] \}$$

(83)

where

$$\rho_{++} = 1 + \zeta S_W \cos \theta_1^i, \rho_{--} = 1 - \zeta S_W \cos \theta_1^i$$

$$\rho_{+-} = 1 - \zeta S_W \cos \theta_2^i, \rho_{-+} = 1 + \zeta S_W \cos \theta_2^i$$

(84)

However, using $I(E_{W+}, E_{W-})$ the fractional sensitivity for measurement of $\zeta$ at the Tevatron at 2 TeV is only 38% versus 2.2% by using $I(E_{W+}, E_{W-}, \tilde{\theta}_1, \tilde{\theta}_2)$. The “fractional sensitivity” is explicitly defined by Eq.(36) in [6]. Similarly, at the LHC at 14 TeV, the fractional sensitivity for measurement of $\zeta$ with $I_2$ is 2.3% versus 0.39% with $I_4$. This shows the importance of including the analyzing power of the second stage in the decay sequence, i.e. W decay- polarimetry, c.f. Sec.

28
5.3. It is also important to note that only the partial width and the $\zeta$ helicity parameter appear in this stage-one spin-correlation function. To measure the other helicity parameters ($\xi, \sigma, \ldots$), one needs to use stage-two W or b decay-polarimetry, and/or other spin-correlation functions.

This use of W decay-polarimetry and $I_4$ to significantly increase the analyzing powers does not directly make use of the threshold-type kinematics at the Tevatron of the $q\bar{q} \rightarrow t\bar{t}$ reaction. See the series of papers by Parke, Mahlon, and Shadmi [7] for spin-correlation analyses which investigate threshold techniques.

Some modern Monte Carlo simulations do include spin-correlation effects, for instance KORALB for $e^-e^+$ colliders[16]. The simple general structure and statistical sensitivities of the S2SC function $I_4$ show that spin-correlation effects should also be included in Monte Carlo simulations for $p\bar{p}$, or $pp, \rightarrow t\bar{t}X \rightarrow \ldots$. In such a Monte Carlo it should be simple and straightforward to build in the amplitudes for production of L-polarized and T-polarized $W^\pm$’s from distinct Lorentz-structure sources. Thereby, spin-correlation techniques and the results in this paper can be used for many systematic checks. For example, they could be used to experimentally test the CP and T invariance “purity” of detector components and of the data analysis by distinguishing which coefficients are or aren’t equal between various experimental data sets analyzed separately for the $t$ and $\bar{t}$ modes.

Assuming only $b_L$ couplings[17], a simple way for one to use a Monte Carlo simulation to test for possible CP violation is to add an $S + P$ coupling (to the standard $V - A$ coupling) in the $t$ decay mode such that the $S + P$ contribution has an overall complex coupling factor “c” in the $t$ mode and a complex factor “d” in the $\bar{t}$ mode. This will generate a difference in moduli and phases between the $t, \bar{t}$ modes. Then the 2 tests for CP violation are whether $|c| = |d|$, $\text{arg}(c) = \text{arg}(d)$.
experimentally.

To be model independent and of greater use to theorists, experimental analyses should not assume a mixture of only $V$ and $A$ current couplings in top decays. By consideration of polarized-partial-widths there are several fundamental quantities besides the chirality parameter and the total partial width which can be directly measured. For example, there are three logically independent tests for only $b_L$ couplings: $\xi = 1$, $\zeta = \sigma$, and $\omega = \eta$ up to $O(m_b)$ corrections[18]. If $\tilde{T}_{FS}$-violation were to occur, then the non-zero parameters $\omega' = \eta'$ if there are only $b_L$ couplings.

Acknowledgments

We thank experimental and theoretical physicists for discussions and assistance, in particular with respect to matters specific to hadron colliders. We thank Ming Yang; and for computer services, John Hagan, Christine Place-Sweet, and Mark Stephens. This work was partially supported by U.S. Dept. of Energy Contract No. DE-FG 02-96ER40291.

[17] Historically, for a complete Lorentz-invariant characterization of the charged current, there have been two popular choices for the minimal sets of couplings: Express the vector matrix element $< b|v^\mu(0)|t>$ either in terms of $V, f_M,$ and $S^-(\text{recall } S^- \text{ doesn’t contribute to the on-shell } W^+ \text{ mode})$ or of $V, S$ and $S^-$. Correspondingly, express the axial $< b|a^\mu(0)|t>$ either in terms of $A, f_E,$ and $P^-(P^-\text{doesn’t contribute to the on-shell } W^+ \text{ mode})$ or of $A, P$ and $P^-$. So if there are only $b_L$ couplings, then the chiral combinations of $V - A$ and $S + P$ can contribute significantly to the $W^+$ mode since $m_b/m_t, m_b/m_w \approx 0$. To include $b_R$ couplings, one would add $V + A$ and $S - P$ via an additional “$g_R \gamma^\mu(1 + \gamma_5) + e(k + p)^\mu(1 - \gamma_5)$” for $t$ and “$\bar{g}_R \gamma^\mu(1 + \gamma_5) + f(k + p)^\mu(1 - \gamma_5)$” for $\bar{t}$ where “ $e$ ” and “ $f$ ” are different complex coupling factors. In each case this gives the expected number of independent variables. Measurement of the overall relative phase of the $\lambda_b = -\frac{1}{2}$ and $\lambda_b = \frac{1}{2}$ couplings (and for the $\lambda_b = \pm \frac{1}{2}$ couplings of the anti-$b$ quark) by S2SC’s using $b$ quark-polarimetry is considered in Ref.[6].

[18] The corrections for $m_b = 4.5 GeV$ are given numerically in Table 3 of Ref. [6] and follow analytically from Eqs.(25-28) in the present paper.
Table Captions

Table 1: Analytic form of the helicity parameters for \( t \to W^+ b \) decay for unique Lorentz couplings: In this and following table, the mass ratios are denoted by \( w/t \equiv m_w/m_t \). We do not tabulate \( \omega' \) and \( \eta' \) because \( \omega' = \eta' = 0 \) if either (i) there is a unique Lorentz coupling, (ii) there is no \( \tilde{T}_{FS} \)-violation, and/or (iii) there is a “V and A, \( m_b = 0 \)” masking mechanism, see remark (5) in Sec. 1.

Table 2: Analytic forms and numerical values of the partial-width-intensities for polarized final states for unique Lorentz couplings.

Table 3: Helicity parameters for \( t \to W^+ b \) decay to leading-order in the case of a single additional chiral coupling \( (g_\ell) \) which is small relative to the standard \( V - A \) coupling \( (g_L) \). This table is for the \( V + A \) and for the \( S \pm P \) couplings. The next table is for additional tensorial couplings. In this paper \( \mathcal{R} \mathcal{E} \) ( \( \mathcal{I} \mathcal{M} \) ) denote respectively the real (imaginary) parts of the quantity inside the parentheses.

Table 4: Same as previous table except this table is for additional tensorial couplings. Here \( g_\pm = f_M \pm f_E \) involves \( k_t - p_b \) whereas \( \tilde{g}_\pm = g^+_{T_\pm T_5^\pm} \) involves \( k_t + p_b \), see Eqs.(22). Here \( m_t \) = mass of the \( t \) quark.

Figure Captions

FIG. 1: The three angles \( \theta_1', \theta_2' \) and \( \phi \) describe the first stage in the sequential-decays of the \((t\bar{t})\) system in which \( t \to W^+ b \) and \( \bar{t} \to W^- \bar{b} \). From (a) a boost along the negative \( z_1' \) axis transforms the kinematics from the \( t_1 \) rest frame to the \((t\bar{t})_{cm} \) frame and, if boosted further, to the \( \bar{t}_2 \) rest frame shown in (b).
FIG. 2: The two pairs of spherical angles $\theta^t_1, \phi^t_1$ and $\tilde{\theta}_a, \tilde{\phi}_a$ describe the respective stages in the sequential decay $t \to W^+ b$ followed by $W^+ \to j_d j_u$, or $W^+ \to l^+ \nu$. The spherical angles $\tilde{\theta}_a, \tilde{\phi}_a$ specify the $j_d$ jet (or the $l^+$) momentum in the $W^+$ rest frame when the boost is from the $t_1$ rest frame. For the hadronic $W^+$ decay mode, we use the notation that the momentum of the charge $\frac{1}{3}e$ jet is denoted by $j_d$ and the momentum of the charge $\frac{2}{3}e$ jet by $j_u$. In this figure, $\phi^t_1$ is shown equal to zero for simplicity of illustration.

FIG. 3: This figure is symmetric versus Fig. 2. The spherical angles $\tilde{\theta}_b, \tilde{\phi}_b$ specify the $j_d$ jet (or the $l^-$) momentum in the $W^-$ rest frame when the boost is from the $\bar{t}_2$ rest frame.

FIG. 4: The spherical angles $\tilde{\theta}_1, \tilde{\phi}_1$ specify the $j_d$ jet (or the $l^+$) momentum in the $W^+$ rest frame when the boost is directly from the $(tt)_{cm}$ frame. Similarly, $\tilde{\theta}_2, \tilde{\phi}_2$ specify the $j_d$ jet (or the $l^-$) momentum in the $W^-$ rest frame. The $W^+W^-$ production half-plane specifies the positive $x_1$ and $x_2$ axes.

FIG. 5: Display of test for $\tilde{T}_{FS}$ violation using the right-triangle relation, Eq.(60): First, side $a = \eta + \omega$ is drawn with its uncertainty $\delta_a$ and then the hypotenuse $c = \frac{1}{2}\sqrt{[(1 + \xi)^2 - (\sigma + \zeta)^2]}$ is cast to form a right-triangle. $c$’s uncertainty is shown as $\delta_c$. A resulting non-zero side $b = \eta' + \omega'$ would imply that $\tilde{T}_{FS}$ is violated either dynamically or because of a fundamental violation of canonical $T$-invariance.

FIG. 6: Display of the $W^+$ energy-$W^-$ energy correlation, $I^c_{2cm}(\cos \theta^t_1, \cos \theta^t_2)$ as predicted by the standard model for $pp \to t\bar{t}X$ (LHC). The contours shown are for $10^6$ events over 10bins · 10bins (LHC). This saddle surface peaks at $(\pm 1, \mp 1)$; and the levels range from 9,478, to 10,522 with spacing 116. [At the Tevatron at 2TeV, the saddle is inverted with dips at $(\pm 1, \mp 1)$; with levels ranging from 294 to 306 with spacing 1.2 for $3 \cdot 10^4$ events].
FIG. 7: First of 8 figures showing the $\cos \theta_1^t$, $\cos \tilde{\theta}_1$ behaviour of the elements of the “reduced” composite-density-matrix $\rho_{hh'}$. These also show the dependence as the total center-of-mass energy $E_{cm}$ is changed. This figure is for $\rho_{++}$ and $E_{cm} = 380$ GeV; the next figure is for $E_{cm} = 450$ GeV. This saddle surface peaks at about $(1, 0)$, $(-1, -1)$; and the levels range from 0.1300 to 1.3923 with spacing 0.1266.

FIG. 8: The $\cos \theta_1^t$, $\cos \tilde{\theta}_1$ behaviour of $\rho_{++}$ for $E_{cm} = 450$ GeV. The surface peaks at about $(1, 0)$, and falls towards the 3 corners; the levels range from 0.1751 to 1.3422 with spacing 0.1220.

FIG. 9: The $\cos \theta_1^t$, $\cos \tilde{\theta}_1$ behaviour of $\rho_{--}$ for $E_{cm} = 380$ GeV. The saddle surface peaks at about $(-1, 0), (1, -1)$; the levels range from 0.1231 to 1.2274 with spacing 0.1227.

FIG. 10: The $\cos \theta_1^t$, $\cos \tilde{\theta}_1$ behaviour of $\rho_{--}$ for $E_{cm} = 450$ GeV. The surface peaks at about $(-1, 1), (-0.5, -1)$; the levels range from 0.1404 to 1.4002 with spacing 0.1400.

FIG. 11: The $\cos \theta_1^t$, $\cos \tilde{\theta}_1$ behaviour of $\text{Re}[\rho_{+-}]$ for $E_{cm} = 380$ GeV. The surface peaks at about $(-0.25, 0.25)$; the levels range from $-0.5392$ to 0.4179 with spacing 0.1063.

FIG. 12: The $\cos \theta_1^t$, $\cos \tilde{\theta}_1$ behaviour of $\text{Re}[\rho_{+-}]$ for $E_{cm} = 450$ GeV. The surface peaks at about $(-0.8, 0.9)$; the levels range from $-0.5960$ to 0.4490 with spacing 0.1161.

FIG. 13: The $\cos \theta_1^t$, $\cos \tilde{\theta}_1$ behaviour of $\text{Imag}[\rho_{+-}]$ for $E_{cm} = 380$ GeV for arbitrary overall normalization $\omega' = \eta' = 1$. The surface peaks at about $(-0.5, 0.5)$; the levels range from $-0.5025$ to 0.1293 with spacing 0.0702.

FIG. 14: The $\cos \theta_1^t$, $\cos \tilde{\theta}_1$ behaviour of $\text{Imag}[\rho_{+-}]$ for $E_{cm} = 450$ GeV for arbitrary overall normalization $\omega' = \eta' = 1$. The surface peaks at about $(-1, 0.8)$; the levels range from $-0.7025$ to 0.2842 with spacing 0.1096.
