A family of non-Volterra quadratic operators corresponding to permutations

U. U. Jamilov

Abstract. In the present paper we consider a family of non-Volterra quadratic stochastic operators depending on a parameter $\alpha$ and study their trajectory behaviors. We find all fixed points for a non-Volterra quadratic stochastic operator on a finite-dimensional simplex. We construct some Lyapunov functions. A complete description of the set of limit points is given, and we show that such operators have the ergodic property.

1 Introduction

The quadratic stochastic operators frequently arise in many models of mathematical genetics, namely, in the theory of heredity (see [1], [2], [3], [5], [7], [9], [10], [12], [13], [14], [16], [18], [20], [21], [22], [23], [25], [26], [27], [28], [29]). Consider a biological population and suppose that each individual in this population belongs precisely to one of the species (genotype) $1, \ldots, m$. The scale of species is such that the species of the parents $i$ and $j$, unambiguously, determine the probability of every species $k$ for the first generation of direct descendants. Denote this probability, called the heredity coefficient, by $p_{ij,k} = P(k|(i,j))$. It is then obvious that $p_{ij,k} \geq 0$ for all $i, j, k$ and that

$$\sum_{k=1}^{m} p_{ij,k} = 1, \quad i, j, k = 1, \ldots, m.$$ 

The state of the population can be described by the tuple $(x_1, x_2, \ldots, x_m)$ of species probabilities, that is, $x_k = P(k)$ is the fraction of the species $k$ in the total population.

In the case of panmixia (random interbreeding) the parent pairs \( i \) and \( j \) arise for a fixed state \( \mathbf{x} = (x_1, x_2, \ldots, x_m) \) with probability \( x_i x_j = P(i, j) = P(i)P(j) \). Hence, the total probability of the species \( k \) in the first generation of direct descendants is defined by

\[
x'_k = \sum_{i,j=1}^{m} P(k|(i,j))P(i)P(j) = \sum_{i,j=1}^{m} p_{ij,k}x_i x_j, \quad k = 1, \ldots, m.
\]

The association \( \mathbf{x} \mapsto \mathbf{x}' \) defines an evolutionary quadratic operator. Thus evolution of a population can be studied as a dynamical system of a quadratic stochastic operator [23]. See [9] and [24] for a review of QSOs. Recently in [22], [11] a quasi-strictly non-Volterra QSO is studied. We refer the reader to [19] for a review on convex combinations of quadratic stochastic operators. The main goal of the present paper is to study a family of operators which contains a convex combination of two non-Volterra QSOs.

The paper is organised as follows. In Section 2 we recall definitions and well known results from the theory of Volterra and non-Volterra QSOs. In Section 3 we consider a class of non-Volterra QSOs and study trajectory behaviors of such operators. We show that each QSO from this class has the two fixed points. Moreover, we prove that such operator is ergodic.

2 Preliminaries

Let

\[
S^{m-1} = \left\{ \mathbf{x} = (x_1, x_2, \ldots, x_m) \in \mathbb{R}^m : \text{for any } i, \ x_i > 0 \text{ and } \sum_{i=1}^{m} x_i = 1 \right\}
\]

be the \((m - 1)\)-dimensional simplex. A map \( V \) of \( S^{m-1} \) into itself is called a quadratic stochastic operator (QSO) if

\[
(V\mathbf{x})_k = \sum_{i,j=1}^{m} p_{ij,k}x_i x_j
\]

for any \( \mathbf{x} \in S^{m-1} \) and for all \( k = 1, \ldots, m \), where

\[
p_{ij,k} \geq 0, \quad p_{ij,k} = p_{ji,k} \quad \text{for all } i, j, k \quad \text{and} \quad \sum_{k=1}^{m} p_{ij,k} = 1.
\]

Assume \( \{\mathbf{x}^{(n)} \in S^{m-1} : n = 0, 1, 2, \ldots \} \) is the trajectory (orbit) of the initial point \( \mathbf{x} \in S^{m-1} \), where \( \mathbf{x}^{(n+1)} = V(\mathbf{x}^{(n)}) \) for all \( n = 0, 1, 2, \ldots \), with \( \mathbf{x}^{(0)} = \mathbf{x} \).

One of the main problems in mathematical biology is to study the asymptotic behavior of the trajectories. This problem deeply studied for the Volterra QSOs (see [7], [8]).

**Definition 2.1.** A quadratic stochastic operator is called a *Volterra operator* if
\[ p_{ij,k} = 0 \text{ for any } k \notin \{i, j\}, \quad i, j, k = 1, \ldots, m. \]

**Definition 2.2.** A point \( x \in S^{m-1} \) is called a periodic point of \( V \) if there exists an \( n \) so that \( V^n(x) = x \). The smallest positive integer \( n \) satisfying the above is called the prime period or least period of the point \( x \). A period-one point is called a fixed point of \( V \).

Denote the set of all fixed points by \( \text{Fix}(V) \) and the set of all periodic points of (not necessarily the smallest) period \( n \) by \( \text{Per}_n(V) \). Evidently that the set of all iterates of a periodic point form a periodic trajectory (orbit).

Let \( D_x V(x^*) = (\partial V_i / \partial x_j)(x^*) \) be a Jacobian of \( V \) at the point \( x^* \).

**Definition 2.3 ([4]).** A fixed point \( x^* \) is called hyperbolic if its Jacobian \( D_x V(x^*) \) has no eigenvalues on the unit circle.

**Definition 2.4 ([4]).** A hyperbolic fixed point \( x^* \) is called:

i) **attracting**, if all the eigenvalues of the Jacobian \( D_x V(x^*) \) are less than 1 in absolute value;

ii) **repelling**, if all the eigenvalues of the Jacobian \( D_x V(x^*) \) are greater than 1 in absolute value;

iii) a saddle, otherwise.

**Definition 2.5.** A QSO \( V \) is called regular if for any initial point \( x \in S^{m-1} \), the limit \( \lim_{n \to \infty} V(x^{(n)}) \) exists. Note that the limit point is a fixed point of a QSO. Thus, the fixed points of a QSO describe limit or long run behavior of the trajectories for any initial point. The limit behavior of trajectories and fixed points play an important role in many applied problems (see [3], [5], [7], [9], [12], [13], [15], [16], [18], [21], [23], [25], [28], [29]). The biological treatment of the regularity of a QSO is rather clear: in the long run the distribution of species in the next generation coincides with the distribution of species in the previous one, i.e., it is stable.

For nonlinear dynamical systems (1) Ulam [27] suggested an analogue of a measure-theoretic ergodicity, the following ergodic hypothesis:

**Definition 2.6.** A QSO \( V \) is said to be ergodic if the limit

\[ \lim_{n \to \infty} \frac{1}{n} \sum_{k=0}^{n-1} V^k(x) \]

exists for any \( x \in S^{m-1} \).

On the basis of numerical calculations Ulam, in [27], conjectured that the ergodic theorem holds for any QSO. In [28] Zakharevich proved that this conjecture is false in
general. Later, in [6], a sufficient condition of non-ergodicity for QSOs defined on $S^2$ was established. In [5] have shown the correlation between non-ergodicity of Volterra QSOs and rock-paper-scissors games. In [20] the random dynamics of Volterra QSOs is studied.

The biological treatment of non-ergodicity of a QSO is the following: in the long run the behavior of the distributions of species is unpredictable. Note that a regular QSO is ergodic, but in general from ergodicity does not follow regularity.

Let $\omega_V(x(0))$ be the set of limit points of the trajectory

$$\{V^n(x(0)) \in S^{m-1}: n = 0, 1, 2, \ldots\}.$$  

**Definition 2.7.** A continuous function $\varphi: S^{m-1} \to R$ is called a Lyapunov function for a QSO $V$ if $\varphi(V(x)) \geq \varphi(x)$ for all $x$ (or $\varphi(V(x)) \leq \varphi(x)$ for all $x$).

Note that a Lyapunov function is very helpful to describe an upper estimate of $\omega_V(x(0))$.

**Definition 2.8.** A permutation $\pi$ of $E_n = \{1, \ldots, n\}$ is a $k$–cycle if there exists a positive integer $k$ and an integer $i \in E_n$ such that

1. $k$ is the smallest positive integer such that $\pi^k(i) = i$, and
2. $\pi$ fixes each $j \in E_n \setminus \{i, \pi(i), \ldots, \pi^{k-1}(i)\}$.

The $k$-cycle $\pi$ is usually denoted $(i, \pi(i), \ldots, \pi^{k-1}(i))$.

The set $\text{supp}(\pi) = \{i \in E_n : \pi(i) \neq i\}$ denotes the support of $\pi$ and we let $\text{supp}(k)$ denote the support of the $k$-cycle, that is, the set

$$\text{supp}(k) = \{i, \pi(i), \ldots, \pi^{k-1}(i)\}.$$  

Any permutation can be represented in the form of a product of cycles without common elements (i.e. disjoint cycles) and this representation is unique to within the order of the factors.

Let $\pi = \tau_1 \tau_2 \ldots \tau_q$ be a permutation of the set $E_{m-1} = \{1, \ldots, m-1\}$, where $\tau_1, \ldots, \tau_q$ are disjoint cycles and we denote by $\text{ord}(\tau_i)$ the order of a cycle $\tau_i$. Evidently that

$$\text{supp}(\tau_1) \cup \cdots \cup \text{supp}(\tau_q) = \text{supp}(\pi) \quad \text{and} \quad \text{supp}(\tau_i) \cap \text{supp}(\tau_j) = \emptyset, \quad \text{for any} \quad i \neq j.$$  

The following notations will be used in the below. Let

$$\partial S^{m-1} = \{x \in S^{m-1}: x_i = 0 \text{ for at least one } i \in \{1, 2, \ldots, m\}\}$$

denote the boundary of $S^{m-1}$ and let $\text{int} S^{m-1} = \{x \in S^{m-1}: x_1 x_2 \cdots x_m > 0\}$ be the interior of $S^{m-1}$. 
3 Main results

Consider a non-Volterra QSO defined on a finite-dimensional simplex which has the form

\[ V_{\pi} : \begin{cases} x'_k = 2x_m x_{\pi(k)}, & k = 1, \ldots, m - 1 \\ x'_m = x_m^2 + \left( \sum_{i=1}^{m-1} x_i \right)^2 \end{cases} \] (3)

where \( \pi \) is a permutation on the set \( E_{m-1} \).

It is worth mentioning that if \( \pi = (21)(3) \) then the QSO (3) coincides up to the rearrangement of the coordinates with the quasi-strictly non-Volterra QSO which is studied in [22].

Let \( s = \text{LCM} \left( \text{ord}(\tau_1), \ldots, \text{ord}(\tau_q) \right) \).

Theorem 3.1 ([17]). For the operator \( V_{\pi} \) the following statements are true:

i) if \( x^{(0)} \in \Gamma = \{ x \in S^{m-1} : x_m = 0 \} \cup \{ e_m \} \) then \( \omega_{V_{\pi}}(x^{(0)}) = \{ e_m \} \);

ii) if \( \pi = \text{Id} \) then \( \omega_{V_{\pi}}(x^{(0)}) = \{ \bar{x} \} \) for any \( x^{(0)} \in S^{m-1} \setminus \Gamma \);

iii) if \( \pi \neq \text{Id} \) then \( \omega_{V_{\pi}}(x^{(0)}) = \{ x_\xi, x_\xi^1, \ldots, x_\xi^{s-1} \} \).

Let \( V_1 := V_{\text{Id}} \) and \( V_2 := V_{\pi} \). Consider the convex combination of the QSOs \( V_1, V_2 \), that is,

\[ V_{\alpha} = \alpha V_1 + (1 - \alpha) V_2, \quad \alpha \in [0, 1] \]

It is easy to see that the operator \( V_{\alpha} \) has the form

\[ V_{\alpha} : \begin{cases} x'_k = 2x_m (\alpha x_k + (1 - \alpha) x_{\pi(k)}), & k = 1, \ldots, m - 1 \\ x'_m = x_m^2 + \left( \sum_{i=1}^{m-1} x_i \right)^2 \end{cases} \] (4)

where \( \pi \) is a permutation on the set \( E_{m-1} \).

It is evident that if \( \pi = \text{Id} \) then for any \( \alpha \in [0, 1] \) the operator \( V_{\alpha} \) coincides with the QSO \( V_1 \). The dynamics of the operator \( V_1 \) is given in the Theorem 3.1. In the below we consider the cases \( \pi \neq \text{Id} \).

The QSO (4) can be written as follow

\[ V_{\alpha} : \begin{cases} x'_k = 2x_m (\alpha x_k + (1 - \alpha) x_{\pi(k)}), & k \in \text{supp}(\pi) \\ x'_k = 2x_m x_k, & k \notin \text{supp}(\pi) \\ x'_m = x_m^2 + \left( \sum_{i=1}^{m-1} x_i \right)^2 \end{cases} \] (5)

where \( \pi \) is a permutation on the set \( E_{m-1} \).

Consider the function \( f(x) = 2x^2 - 2x + 1, \quad x \in [0, 1] \). We define \( f^n \) to be the \( n \)-fold composition of \( f \) with itself. One can easily verify the statements of the next proposition about dynamics of the function \( f(x) \).
Proposition 3.2. For the function \( f(x) \) the following statements are true:

1) \( \text{Fix}(f) = \{1, 1/2\} \);
2) \( x = 1 \) is a repelling and the fixed point \( 1/2 \) is an attracting;
3) for any value \( n \geq 2 \) the function \( f(x) \) has no \( n \)-periodic points, different from fixed points;
4) \( \lim_{n \to \infty} f^n(x) = 1/2 \) for any \( 0 < x < 1 \) and \( f(0) = f(1) = 1 \).

Denote \( \text{supp}(x) = \{ i : x_i > 0 \} \) and let \( |\text{supp}(x)| \) be its cardinality.

In the next Proposition we will describe the invariant sets, all fixed points and we give some Lyapunov function.

Proposition 3.3. For the operator \( V_\alpha \) the following statements are true:

1) If \( |\text{supp}(\pi)| < m - 1 \) then \( \Gamma_\beta = \{ x \in S^{m-1} : x_i = 0, \forall i \in \beta \} \) is an invariant set for any \( \beta \subset E_{m-1} \setminus \text{supp}(\pi) \). Also the sets
   \[
   M_{\mu,i} = \left\{ x \in S^{m-1} : \sum_{k \in \text{supp}(\tau_i)} x_k = \mu, \; x_m = 1/2 \right\}
   \]
   and
   \[
   M_{\nu,i,j} = \left\{ x \in S^{m-1} : \sum_{k \in \text{supp}(\tau_i)} x_k = \nu \sum_{k \in \text{supp}(\tau_j)} x_k \right\}
   \]
   are invariant sets, where \( \mu \geq 0, \nu > 0 \);
2) \( \text{Fix}(V_\alpha) = X \cup \{ e_m \} \), where \( e_m = (0, \ldots, 0, 1) \) and
   \[
   X = \{ x \in S^{m-1} : x_k = x_l, \; \forall k, l \in \text{supp}(\tau_i), \; i = 1, \ldots, q, \; x_m = 1/2 \};
   \]
3) For any \( i \in \{1, \ldots, q\} \) the function \( \varphi_i(x) = \sum_{k \in \text{supp}(\tau_i)} x_k \) is a Lyapunov function;
4) For any \( k \notin \text{supp}(\pi) \) the function \( \phi_k(x) = x_k \) is a Lyapunov function.

Proof. i) Let \( |\text{supp}(\pi)| < m - 1 \) then for any \( k \notin \text{supp}(\pi) \) from (5) one easily has \( x'_k = 0 \). Hence it follows that the set \( \Gamma_\beta \) is an invariant set.

Let \( x \in M_{\mu,i} \) and \( \tau_i \) is a cycle then from (3) we have
\[
\sum_{k \in \text{supp}(\tau_i)} x'_k = \sum_{k \in \text{supp}(\tau_i)} (\alpha x_k + (1 - \alpha)x_{\pi(k)})
\]
\[
= \alpha \sum_{k \in \text{supp}(\tau_i)} x_k + (1 - \alpha) \sum_{k \in \text{supp}(\tau_i)} x_{\pi(k)}
\]
\[
= \mu.
\]
Therefore \( V(M_{\mu,i}) \subset M_{\mu,i} \).

Let \( x \in M_{\nu,i,j} \) and \( \tau_i, \tau_j \) cycles then from (3) we have

\[
\sum_{k \in \text{supp}(\tau_i)} x'_k = \frac{2x_m}{2} \sum_{k \in \text{supp}(\tau_i)} x_k = \nu.
\]

Consequently \( V(M_{\nu,i,j}) \subset M_{\nu,i,j} \).

ii) The equation \( V_\alpha(x) = x \) has the following form

\[
\begin{cases}
  x_k = 2x_m (\alpha x_k + (1-\alpha)x_{\pi(k)}), & 1 \leq k \leq m-1, \\
  x_m = 2x_m^2 - 2x_m + 1.
\end{cases}
\]

Due to Proposition 3.2 the last equation of the system (6) has the solutions \( x_m = 1 \) and \( x_m = 1/2 \).

Evidently that if \( x_m = 1 \) then we get the vertex \( e_m = (0, \ldots, 0, 1) \).

For \( x_m = 1/2 \) from the system of equations

\[
x_k = \alpha x_k + (1-\alpha)x_{\pi(k)}, \quad 1 \leq k \leq m-1, \text{ and } x_1 + \cdots + x_{m-1} = \frac{1}{2}
\]

it follows that

\[
x_k = x_{k'} \quad \text{for all } k, k' \in \text{supp}(\tau_i), \quad i = 1, \ldots, q \text{ and }
\]

\[
x_k = x_k \quad \text{for all } k \in \text{Fix}(\pi).
\]

Using the last one has that a point \( x = (x_1, \ldots, x_m) \in X \) is a solution of the system (6).

iii) Let \( \tau_i, i \in \{1, \ldots, q\} \) be a cycle. Then \( f(x) \geq 1/2 \) for any \( 0 < x < 1 \) and we can assume that \( x_m \geq 1/2 \). Then from (3) we have

\[
\varphi_i(V_\alpha(x)) = \sum_{k \in \text{supp}(\tau_i)} x'_k = \sum_{k \in \text{supp}(\tau_i)} 2x_m (\alpha x_k + (1-\alpha)x_{\pi(k)})
\]

\[
= 2x_m \left( \alpha \sum_{k \in \text{supp}(\tau_i)} x_k + (1-\alpha) \sum_{k \in \text{supp}(\tau_i)} x_{\pi(k)} \right)
\]

\[
= 2x_m \left( \alpha \varphi_i(x) + (1-\alpha) \varphi_i(x) \right) = 2x_m \varphi_i(x)
\]

\[
\geq \varphi_i(x).
\]

Therefore the functions \( \varphi_i(x) \) are Lyapunov functions for any \( i \in \{1, \ldots, q\} \).

iv) Using \( x_m \geq 1/2 \) from (5) for any \( k \notin \text{supp}(\pi) \) one easily has that

\[
\phi_k(V_\alpha(x)) = 2x_m x_k \geq x_k = \phi_k(x).
\]

\[\square\]
Corollary 3.4. If \( p = |E_{m-1} \setminus \text{supp}(\pi)| \), then 

\[
\phi(x) = \gamma_1 \phi_1(x) + \cdots + \gamma_p \phi_p(x) \quad \text{and} \quad \varphi(x) = \beta_1 \varphi_1(x) + \cdots + \beta_q \varphi_q(x)
\]

are Lyapunov function for the QSO \( V_\alpha \) for any \( \gamma_1 \geq 0, \ldots, \gamma_p \geq 0 \) and \( \beta_1 \geq 0, \ldots, \beta_q \geq 0 \).

In the next Theorem we give the description of the set of limit points of the trajectories.

Theorem 3.5. For the operator \( V_\alpha \) the following statements are true:

i) if \( x^{(0)} \in \Gamma = \{ x \in S^{m-1} : x_m = 0 \} \cup \{ e_m \} \) then \( \omega_{V_\alpha}(x^{(0)}) = \{ e_m \} \);

ii) if \( \alpha \in (0, 1), \pi \neq \text{Id} \) then \( \omega_{V_\alpha}(x^{(0)}) = \{ b \} \), \( b \in \mathcal{X} \) for any \( x^{(0)} \in S^{m-1} \setminus (\Gamma \cup \mathcal{X}) \);

iii) if \( \alpha = 0, \pi \neq \text{Id} \) then \( \omega_{V_\alpha}(x^{(0)}) = \{ x_1, x_1^1, \ldots, x_1^{s-1} \} \);

iv) if \( \alpha = 1, \pi \neq \text{Id} \) then \( \omega_{V_\alpha}(x^{(0)}) = \{ \bar{x} \} \) for any \( x^{(0)} \in S^{m-1} \setminus \Gamma \).

Proof. i) Evidently that \( V_\alpha(x^{(0)}) = e_m \) for any \( x^{(0)} \in \Gamma \).

ii) Let \( \alpha \in (0, 1) \) and \( x^{(0)} \in S^{m-1} \setminus (\Gamma \cup \mathcal{X}) \). Then by assertion of Proposition 3.2 we obtain \( \lim_{n \to \infty} x_m^{(n)} = 1/2 \). Since \( f(x) \geq 1/2 \) for any \( 0 < x < 1 \) and we can assume that \( x_m \geq 1/2 \).

Let \( k \notin \text{supp}(\pi) \). Due to Proposition 3.3 the function \( \phi_k(x) \) is a Lyapunov function for the QSO (4). Therefore, we have

\[
\phi_k(x^{(n+1)}) \geq \phi_k(x^{(n)}), \quad k \notin \text{supp}(\pi), \quad n = 0, 1, \ldots
\]

that is there exists \( \lim_{n \to \infty} x_m^{(n)} = \lim_{n \to \infty} \phi_k(x^{(n)}) = \xi_k \) for any \( k \notin \text{supp}(\pi) \).

Denote \( \bar{X} = \{ x \in S^{m-1} : b_k = \xi_k, \forall k \notin \text{supp}(\pi), b_m = 1/2 \} \).

Let \( \tau_i, i \in \{1, \ldots, q\} \) be a cycle. Consider the function \( \psi_i(x) = \min_{k \in \text{supp}(\tau_i)} x_k \). Then from (3) we have

\[
\psi_i(V_\alpha(x)) = \min_{k \in \text{supp}(\tau_i)} 2x_m(\alpha x_k + (1 - \alpha)x_{\pi(k)}) \geq \alpha \psi_i(x) + (1 - \alpha)\psi_i(x) = \psi_i(x).
\]

Consequently, we have

\[
\psi_i(x^{(n+1)}) \geq \psi_i(x^{(n)}), \quad i = 1, \ldots, q, \quad n = 0, 1, \ldots
\]

Therefore the sequence \( \{ \psi_i(x^{(n)}) \} \) is an increasing and bounded sequence. Hence it follows existence the following limit \( \lim_{n \to \infty} \psi_i(x^{(n)}) = \xi_i \).

Let \( k \in \text{supp}(\pi) \). It is easy to see that for any \( i \in \{1, \ldots, q\} \)

\[
\psi_i(x) \leq \psi_i(b) \quad \text{and} \quad \psi_i(x) = \psi_i(b) \quad \text{iff} \quad x = b, \quad b \in \bar{X} \cap \mathcal{X}.
\]
Indeed if \( x = b \), \( b \in \bar{X} \cap X \) then it is easily follows that \( \psi_i(x) = \psi_i(b) \) for any \( i \in \{1, \ldots, q\} \). Let \( \psi_i(x) = \psi_i(b) \), \( x \in \bar{X} \) for any \( i \in \{1, \ldots, q\} \) and \( b \in \bar{X} \cap X \) then for any \( i \in \{1, \ldots, q\} \) we get \( \psi_i(x) = x_{i_1} \leq x_{i_2} \leq \cdots \leq x_{i_t} \), where \( t = \text{ord}(\tau_i) \). If we assume that some of the inequalities \( x_{i_1} \leq x_{i_2} \leq \cdots \leq x_{i_t} \) are strong inequalities in this case we have contradiction to \( x \in S^{m-1} \). Therefore we have if \( \psi_i(x) = \psi_i(b) \) for any \( i \in \{1, \ldots, q\} \) and \( b \in \bar{X} \cap X \) then for any \( i \in \{1, \ldots, q\} \) we obtain \( \psi_i(x) = x_{i_1} = x_{i_2} = \cdots = x_{i_t} \).

Next we prove that if \( \zeta_i < \psi_i(b) \) for any \( i \in \{1, 2, \ldots, q\} \), then \( \lim_{n \to \infty} x^{(n)} = b \). Suppose the converse. Then there is a sequence \( \{x^{(n_i)}\}_{i=1,2,3,\ldots} \) such that

\[
\lim_{t \to \infty} x^{(n_t)} = c \neq b. \tag{10}
\]

Using \( \min f(x) = 1/2 \) one has

\[
1 = \frac{\psi_i(b) - \zeta_i}{\psi_i(b) - \zeta_i} = \lim_{t \to \infty} \frac{\psi_i(b) - \psi_i(x^{(n+1)})}{\psi_i(b) - \psi_i(x^{(n)})} \\
= 1 + \lim_{t \to \infty} \frac{\psi_i(x^{(n)}) - 2x^{(n)}(\alpha x^{(n)}_k + (1 - \alpha)x^{(n)}_{\pi(k)})}{\psi_i(b) - \psi_i(x^{(n)})} \\
\leq 1 + \lim_{t \to \infty} \frac{\psi_i(x^{(n)}) - (\alpha x^{(n)}_k + (1 - \alpha)x^{(n)}_{\pi(k)})}{\psi_i(b) - \psi_i(x^{(n)})} \\
< 1.
\]

This is a contradiction. It follows that \( \zeta_i = \psi_i(b) \) for any \( i \in \{1, 2, \ldots, q\} \).

Thus \( \lim_{n \to \infty} x^{(n)} = b \) for any \( \alpha \in (0, 1) \) and an initial \( x^{(0)} \in S^{m-1} \setminus (\Gamma \cup X) \).

The proofs of parts iii) and iv) follows from the Theorem 3.1. \( \square \)

**Corollary 3.6.** The QSO \( V_\alpha \) is an ergodic transformation.

**Acknowledgments**

The author thanks the referees for useful comments which helped to improve the presentation.
