Accurate mapping of quantum Heisenberg magnetic models of spin $s$ on strong-coupling magnon systems

Bang-Gui Liu* and Gerd Czycholl

Institute for Theoretical Physics, Universität Bremen, D–28334 Bremen, Germany

An infinite-$U$ term is introduced into the Holstein-Primakoff-transformed magnon hamiltonian of quantum Heisenberg magnetic models of spin $s$. This term removes the unphysical spin wave states on every site and truncates automatically the expansion in powers of the magnon occupation operator. The resultant strong-coupling magnon hamiltonians are accurately equivalent to the original spin hamiltonians. The on-site $U$ levels and their implications are studied. Within a simple decoupling approximation for our strong-coupling magnon models we can easily reproduce the results for the (sublattice) magnetizations obtained previously for the original spin model. But our bosonic hamiltonians without any unphysical states allow for substantially improved values for the spectral weight in the ground state and for lower ground-state energies than those obtained within previous approximations.

PACS numbers: 75.10Jm and 75.30Ds
1 Introduction

Quantum Heisenberg magnetic models, including ferromagnetic (FM) and antiferromagnetic (AFM) ones, are well-accepted models for insulating ferromagnets and antiferromagnets. The exact analytical solution is limited to one dimension and FM ground states. For general parameters one has to turn to some approximation methods or to numerical work. As for analytical methods, one can work directly with the original Heisenberg model, i.e. using spin operators and their algebra. In this category are decoupling approaches\cite{1, 2}, the spherical approach\cite{3}, the projection method\cite{4}, and an isotropic decoupling approach\cite{5}. The first one was a mean-field approximation in the context of Green functions, the second one was for paramagnetic states, the third one investigated the ground states only, and the last one was for short-range magnetic correlation. Anyway, a treatment in terms of the bosonic magnon operators should be advantageous because of the simpler commutation rules and the Bose statistics. For this purpose one has to map the Heisenberg model on a spin wave model using the well known Holstein-Primakoff\cite{6} or the Dyson\cite{7} transformation. In fact, many experimental physicists tend to describe their experimental results in terms of spin wave theory\cite{10, 11}. But if one chooses the Holstein-Primakoff transformation, a series expansion of a square root term in powers of magnon occupation operators is necessary\cite{3, 8}; and one has to break the spin operator relation \((S^+)\dagger = S^-\) if one chooses Dyson’s spin wave transformation\cite{7, 9}.

The most simple spin wave theory is linear spin wave theory\cite{12, 13}. Some nonlinear effects, namely essentially the next terms in the expansion of the square root, are taken into account in nonlinear spin wave theories\cite{12, 8, 1, 7, 14, 15}. But the Hilbert space on which the spin wave (magnon) operators are defined is much larger than the physical Hilbert space. For spin \(s\) the Hilbert space for a single site has the dimension 2\(s+1\). But the Hilbert space on which the magnon operators operate is infinite dimensional. In 3D ferromagnets there should be only few spin wave excitations at low temperature. As for antiferromagnets, there should be a substantial number of
magnons even at zero temperature as the sublattice magnetization is less than \( s \). The effect of the unphysical magnon states on the physical quantities becomes more serious with increasing temperature, because then a thermal occupation of the unphysical states becomes possible. In the paramagnetic (PM) phase, the unphysical states lead to serious problems. Lindgård and Danielsen \[16\] proposed the matching-of-matrix-elements (MME) method, in which operators with a complicated algebra (like spin operators) are expressed in terms of Bose operators so that not only the commutation rules but also certain matrix elements of the original operators remain unchanged and the matrix elements between unphysical states vanish. This MME-method can be considered to be a generalization of the Holstein-Primakoff transformation. Spin hamiltonians like the Heisenberg model are mapped on an interacting Bose model containing on-site interaction terms, but they operate on a Hilbert space, which has still a much larger dimension than the physical Hilbert space. In Mattis’s book\[12\] a similarity transformation is used to eliminate partly the unphysical states in FM phase. In Takahashi’s modified spin wave theory, the total number of magnons is fixed in the PM phase\[17, 18\]. But on a single site, the dimension of the magnon Hilbert space is still much larger than \( 2s + 1 \). Friedberg, Lee, and Ren \[19\] introduced an on-site interaction term into a lattice Bose Hamiltonian and proved the equivalence of this Bose model with a spin-wave model which is equivalent to a spin-\( \frac{1}{2} \) Heisenberg model; they applied the theorem to the anisotropic ferromagnetic Heisenberg model in a magnetic field\[19\].

In this paper we shall introduce a large-\( U \) term into the Holstein-Primakoff transformed magnon hamiltonian of quantum Heisenberg magnetic models of any spin \( s \). In the \( U \rightarrow \infty \) limit this term rigorously removes the unphysical magnon states on every site so that the magnon Hilbert space is mapped accurately on the original spin state space. At the same time it truncates automatically the high power terms of the magnon operators arising in the series expansion. This approach has some connections with earlier attempts \[13, 19\], but we present a formulation being valid for arbitrary spin \( s \) and apply it to the calculation of physical quantities like the order parameter. We shall study the hierarchy of the on-site \( U \) levels and its
implication on the spin physics. Within a simple decoupling approximation, we can easily reproduce results for the FM magnetization and AFM sublattice magnetization which were obtained previously only in theories working with the original spin operators and were better than the results of conventional spin wave theories. Furthermore our bosonic hamiltonians without unphysical states allow us to obtain improved values for the renormalization of the spectral factor at zero temperature and lower ground-state energies than those of the existing approximations.

2 Bosonic hamiltonians without unphysical states

Our ferromagnetic (FM) and antiferromagnetic (AFM) Heisenberg hamiltonians are defined by

$$H = \pm \sum_{\langle ij \rangle} J_{ij} \left( \frac{1}{2} (S_i^+ S_j^- + S_i^- S_j^+) + S_i^z S_j^z \right)$$ (1)

where $J_{ij}$ is positive and the summation is over the nearest neighbor sites. Here the negative sign corresponds to the ferromagnetic case and the positive sign to the antiferromagnetic case. For the AFM case it is better to make a $\pi$ spin rotation for the operators in one of the two sublattices. The rotated AFM hamiltonian reads

$$H = \sum_{\langle ij \rangle} J_{ij} \left( S_i^+ S_j^- + S_i^- S_j^+ - S_i^z S_j^z \right) - \frac{1}{4} \epsilon N$$ (2)

We choose Holstein-Primakoff (HP) transformation to transform the spin operators into the magnon operators.

$$S_i^- = a_i^\dagger \sqrt{2s - n_i}, \quad S_i^+ = a_i \sqrt{2s - n_i}, \quad S_i^z = s - n_i; \quad n_i = a_i^\dagger a_i$$ (3)

The magnon operators $a_i$ are standard bosonic operators. We prefer HP transformation because Dyson transformation breaks the conjugate relation of the spin operators. When substituting the transformation (3) into the hamiltonians, one obtains the following FM hamiltonian

$$H = \sum_i \epsilon a_i^\dagger a_i - \sum_{\langle ij \rangle} J_{ij} \left[ \frac{1}{2} (a_i^\dagger \sqrt{2s - n_i} \sqrt{2s - n_j} a_j + \text{h.c.}) + a_i^\dagger a_i a_j^\dagger a_j \right] - \frac{1}{4} \epsilon N$$ (4)
and the following AFM hamiltonian

\[ H = \sum_i \epsilon a_i^\dagger a_i + \sum_{\langle ij \rangle} J_{ij} [\frac{1}{2}(a_i^\dagger a_j^\dagger \sqrt{2s - n_i} - n_i \sqrt{2s - n_j} + \text{h.c.}) - a_i^\dagger a_j^\dagger a_j - \frac{1}{4} \epsilon N] \tag{5} \]

Here \( N \) is the total number of the sites, \( \epsilon = JZ/2 \), and \( J \) is the exchange constant in the isotropic case or the largest of the \( J_{ij} \) in the anisotropic case and \( Z \) is the coordination number. Since the operator \( a_i \) is a standard Bose operator, it operates on an infinite dimensional Hilbert space. But the physical Hilbert space corresponding to a single site is spanned by only \( 2s + 1 \) states. The extra states are unphysical. The magnon hamiltonians (4) and (5) are not equivalent to the original spin hamiltonians (1) and (2) if the unphysical states are not removed. For the exact FM ground state it is expected that there is no bosonic excitation so that the unphysical states remain unoccupied at zero temperature. The higher the temperature is, the more serious problems may arise, if the thermal occupation of the unphysical states becomes possible. In the AFM case even the ground state has some substantial bosonic excitations. The largest discrepancy appears in the paramagnetic (PM) phase where the average spin in conventional magnon theory becomes very unreasonable if one tries to calculate it without introducing some constraints.

To remove completely the effect of the unphysical magnon states on every site, we can make their energy levels infinitely higher than those of the physical spin states. We introduce a large \( U \) term into the Holstein-Primakoff transformed hamiltonians. This \( U \) term resembles the strong coupling positive \( U \) term in the Hubbard model of electronic systems. But it is not dynamical, it is introduced only as a constraint to raise the unphysical states infinitely high in energy from the physical states. This means that our new hamiltonians \( H' \) are composed of the original hamiltonians \( H \) and the following \( U \) terms.

\[ H_U = \frac{1}{(2s + 1)!} U a_i^{\dagger(2s+1)} a_i^{(2s+1)} \]

In fact, \( U \) should be considered to be infinite. Therefore, the unphysical states should be pushed infinitely high in energy from the physical states by the \( U \) term.
For the half spin case, the resultant FM hamiltonian reads

\[
H' = \sum_i (\epsilon a_i^\dagger a_i + \frac{1}{2} U a_i^2 a_i^2) - \sum_{\langle ij \rangle} J_{ij} \left[ \frac{1}{2} (a_i^\dagger a_j + a_i a_j^\dagger) + a_i^\dagger a_i a_j^\dagger a_j \right] - \frac{1}{4} \epsilon N
\]  

(6)

and the AFM hamiltonian reads

\[
H' = \sum_i (\epsilon a_i^\dagger a_i + \frac{1}{2} U a_i^2 a_i^2) + \sum_{\langle ij \rangle} J_{ij} \left[ \frac{1}{2} (a_i^\dagger a_j + a_i a_j^\dagger) - a_i^\dagger a_i a_j^\dagger a_j \right] - \frac{1}{4} \epsilon N
\]  

(7)

Here we need no chemical potential since the unphysical magnon states have been removed rigorously by the infinite-\(U\) term. Furthermore the square root terms \(\sqrt{2s - a_i^\dagger a_i}\) in the hamiltonians (4), (5) have been expanded as

\[
\sqrt{2s - a_i^\dagger a_i} = \sqrt{2s} - (\sqrt{2s} - \sqrt{2s - 1}) a_i^\dagger a_i + \left( \sqrt{2s} - 2 \sqrt{2s - 1} + \sqrt{2s - 2} \right) \frac{a_i^2 a_i^2}{2!} + \text{(terms of } a_i^\dagger a_i^n, n \geq 3) \]  

(8)

and all terms \(a_i^\dagger a_i^n\) with \(n \geq 2s\) can be neglected after introduction of the U-terms because their energy is already shifted to infinity by the U-term. In the cases of \(s = \frac{1}{2}\), all operator product terms including \(a_i^\dagger a_j^m\) \((m > 1 \text{ and/or } n > 1)\) disappear automatically so that the hamiltonians (4) and (5) are very simple. For larger spin \(s\), there are more terms resulting from the expansion of the square root because the terms including \(a_i^\dagger a_j^m\) \((m \leq 2s \text{ and } n \leq 2s)\) are allowed. This expansion is different from the 1/s expansion in the spin wave theories. We make no approximation in the expansion (8). The \(U\) term not only pushes the unphysical states infinitely high from the physical states but also truncates automatically the expansion of the square root. Our expansions of \(S_i^+\) and \(S_i^-\) are composed of only 2s terms and \(S_i^z\) is \(s - a_i^\dagger a_i\), being different from the infinite sums of the three spin operators in Ref [16]. Our mapping works for ferromagnetic and antiferromagnetic Heisenberg models of any spin \(s\), being in contrast to the equivalence theorem which works only for half-spin system[19].
3 On-site $U$ levels

To study the effect of the $U$ term, we first study the on-site $U$ levels. In the half-spin case, we have the following commutation relations:

$$[a_i^{\dagger} a^2, a_i^{\dagger} p a^q]_-= [p(p-1) - q(q-1)] a_i^{\dagger} p a^q + 2(p-q) a_i^{\dagger(p+1)} a^{(q+1)}$$  \hspace{1cm} (9)

For $q = 0$ and $p = n$, we obtain by application of this expression on the magnon vacuum:

$$H_{U}^{1/2} |n\rangle = \frac{n(n-1)U}{2} |n\rangle$$  \hspace{1cm} (10)

where $H_{U}^{1/2} = \frac{U}{2} a_i^{\dagger} a^2$ and $|n\rangle = a_i^{\dagger n} |0\rangle$. $|n\rangle$ is an eigenstate of $H_{U}^{1/2}$. The magnon states for the lowest five $U$ levels are shown in the left part of Figure 1. The magnon vacuum state $|0\rangle$ and the single magnon state $a_i^{\dagger} |0\rangle$ correspond to the two physical spin states. The multiple magnon states $a_i^{\dagger n} |0\rangle$ ($n > 1$) are separated from these physical states by an energy of the magnitude of $U$ and are thus projected out from the Hilbert space in the limit $U \to \infty$. Therefore, we expect $\langle a_i^{\dagger n} a_i^n \rangle = 0$ ($n \geq 2$) when $U$ tends to $\infty$.

As for the case of spin 1, we have the following operator equality.

$$[a_i^{\dagger 2} a^2, a_i^{\dagger} p a^q]_-= [p(p-1)(p-2) - q(q-1)(q-2)] a_i^{\dagger} p a^q + 3[p(p-1) - q(q-1)] a_i^{\dagger(p+1)} a^{(q+1)} + 3(p-q) a_i^{\dagger(p+2)} a^{(q+2)}$$  \hspace{1cm} (11)

The on-site $U$ part of the hamiltonian is $H_{U}^{1} = \frac{U}{6} a_i^{\dagger 3} a^3$. We obtain the following eigenstate equation.

$$H_{U}^{1} |n\rangle = \frac{n(n-1)(n-2)U}{6} |n\rangle$$  \hspace{1cm} (12)

The states within the first five on-site levels are shown in the right part of Figure 1. At the ground level are the magnon vacuum $|0\rangle$, single magnon state $a_i^{\dagger} |0\rangle$, and double magnon state $a_i^{\dagger 2} |0\rangle$. They correspond to the three physical states of the spin operator: $-1, 0, 1$. Other states are separated from the physical states by energies of at least $U$. Therefore, we expect $\langle a_i^{\dagger n} a_i^n \rangle = 0$ ($n \geq 3$) when $U$ tends to $\infty$. 
For higher spins $s$, we can derive some operator equations similar to (9) and (11). Always we have $2s + 1$ magnon states on the ground level, corresponding to the total physical spin states, and the unphysical states are separated from the physical states by energies of order $U$. We expect $\langle a_i^\dagger a_i^n \rangle = 0 \ (n \geq 2s + 1)$ when $U$ tends to $\infty$.

4 First-order decoupling approximation

Since the $U$ is very large, we cannot apply Hartree-Fock approximation to the magnon Hamiltonians. Now we study the FM and AFM systems of half-spin in a first-level decoupling approach of its equation of motion. We choose $a_i$ as our dynamical variable.

The FM case: Using the Zubarev notation for the commutator Green function

$$\langle [A(t), B] \rangle_z = -i \int_{-\infty}^{+\infty} \theta(t) \langle A(t), B \rangle e^{izt} \quad (13)$$

we get the equation of motion

$$(z - \epsilon) \langle a_i^\dagger a_j \rangle_z = \delta_{ij} - \frac{1}{2} \sum_l J_{il} \langle a_i^\dagger a_j^\dagger \rangle_z - \sum_l J_{il} \langle a_i n_l a_j^\dagger \rangle_z + U \langle a_i^\dagger a_i^2; a_j^\dagger \rangle_z \quad (14)$$

In the above equation the third term comes from the inter-site interaction and the fourth term comes from the on-site large $U$ interaction. Without these two terms, one recovers the conventional FM linear spin wave theory. Since $U$ is very large, the fourth term cannot be neglected. We have to write down its equation of motion to get closed equations.

$$(z - \epsilon - U - J Z n) \langle a_i^\dagger a_i^2; a_j^\dagger \rangle_z = 2n \delta_{ij} - n \sum_l J_{il} \langle a_i a_j^\dagger \rangle_z \quad (15)$$

Here $n_l = a_i^\dagger a_i$ denotes the magnon occupation operator, $n = \langle n_i \rangle$ its thermal expectation value. In the latter equation other higher order Green functions have been neglected because they involve an even higher multiple magnon occupation of a single site and, therefore, vanish for infinite $U$. Furthermore a decoupling
approximation between magnon and occupation operators for different sites has been made, but operators operating on the same site are not decoupled. Since $U$ tends to infinite and $z$ is of order of $J$, the prefactor on the left hand side can be simplified into $-U$. Substituting it into (14) and using once more the mentioned decoupling approximation, we get

$$(z - (1 - 2n)\epsilon)\langle\langle a_i; a_j^\dagger \rangle \rangle_z = (1 - 2n)\delta_{ij} - \frac{1}{2}(1 - 2n)\sum_l J_{il}\langle\langle a_i; a_j^\dagger \rangle \rangle_z$$

(16)

By Fourier transformation we obtain for the $\vec{k}$-dependent Green function

$$G_{\vec{k}}(z) = \frac{1}{N} \sum_{i,j} \langle\langle a_i; a_j^\dagger \rangle \rangle_z e^{i\vec{k}\cdot(\vec{R}_i - \vec{R}_j)} = \frac{1 - 2n}{z - (1 - 2n)\epsilon(1 - r_k)}$$

where

$$r_k = \frac{1}{Z} \sum_{\Delta} e^{i\vec{k}\cdot\vec{\Delta}}$$

(18)

denotes the (dimensionless) magnon dispersion characteristic for the lattice under consideration; $\vec{\Delta}$ denotes the nearest neighbor vectors. For $d$-dimensional simple cubic lattice, we have

$$r_k = \frac{1}{d} \sum_{i=1}^{d} \cos k_i$$

The self-consistency equation to determine $n$ reads

$$n = (1 - 2n)\frac{1}{N} \sum_{\vec{k}} 1/\left[\exp \frac{JZ(1 - 2n)(1 - r_k)}{2T} - 1\right]$$

(19)

This equation is equivalent to that expressed in terms of spin operator average, $\langle S_i^z \rangle$, obtained by Bogoliubov[1]. In the limit $T \to 0$ we obtain $n = 0$ or 1 as solutions of the above equation. These two solutions correspond to $\langle S_i^z \rangle = \frac{1}{2}$ or $-\frac{1}{2}$, respectively, since $S_i^z = \frac{1}{2} - n_i$. When temperature increases to the Curie Temperature $T_c$, the two branches converge to $n = \frac{1}{2}$, or $\langle S_i^z \rangle = 0$. For finite but small $T$ we obtain

$$\langle S_i^z \rangle = \frac{1}{2} - \alpha(T/J)^{3/2}$$

where $\alpha$ is a positive constant. When $T \to T_c$, $(1 - 2n)$ tends to zero so that we can derive an asymptotic expression of $\langle S_i^z \rangle$ as follows.

$$\langle S_i^z \rangle \propto \sqrt{1 - T/T_c}, \quad T_c = JZ/4P, \quad P = \frac{1}{N} \sum_k 1/(1 - r_k)$$

(20)

In two or one dimensions the $\vec{k}$-integration diverges, i.e. $P = \infty$ so that $T_c = 0$ in accordance with the Mermin-Wagner theorem [24].
For $T \leq T_c$ in three dimensions, we obtain two solutions. These two solutions correspond to the two degenerate ferromagnetic solutions. The resulting order parameter, i.e. the magnetization is shown in Figure 2. The 3D results of the conventional nonlinear and linear spin wave theories are also presented for comparison. The nonlinear spin wave theory produces an unphysical first-order transition at $T = 0.98J$. The magnetization obtained within our strong-coupling magnon theory according to (19) is obviously an essential improvement in the whole temperature regime; we obtain as the critical (Curie) temperature $T_c = 0.989J$ whereas the series expansion result for $T_c$ is $T_c = 0.889J$. It is interesting to compare this $T_c$ result to the spherical approximation for paramagnetic phase. The spherical approximation result, $T_c = 0.82J$, is slightly smaller than the numerical results, whereas our result $T_c = 0.989J$ is on the higher temperature side of the numerical results. Our ground state energy is $-0.25Jd$ per site in two and three dimensions, as it should be.

The AFM case: In this case the Green function $G_{ij}(z) = \langle \langle a_i; a^\dagger_j \rangle \rangle_z$ only is not sufficient but we have to consider also the "anomalous" one-particle Green function $F_{ij}(z) = \langle \langle a_i^\dagger; a^\dagger_j \rangle \rangle_z$. We obtain the following equation of motion for the Green function $G_{ij}(z)$.

\[
(z - \epsilon)G_{ij} = \delta_{ij} + \frac{1}{2} \sum_l J_d F_{lj} - \sum_l J_d \langle \langle a_i n_l; a_j^\dagger \rangle \rangle_z + U \langle \langle a_i^\dagger a_i^2; a_j^\dagger \rangle \rangle_z \quad (21)
\]

In the above equation the third term comes from the inter-site interaction and the fourth term comes from the on-site large $U$ interaction. Without these two terms, one obtains the existing AFM linear spin wave theory. In the same way as in the FM case, we have to write down a further equation of motion for the $U$ term. It reads

\[
(z - \epsilon - U - JZn) \langle \langle a_i^\dagger a_i^2; a_j^\dagger \rangle \rangle_z = 2n \delta_{ij} + n \sum_l J_d F_{lj}(z) \quad (22)
\]

where we have again decoupled magnon occupation number operators and single magnon operators at different lattice sites. Inserting this into (14) and using the
decoupling approximation once more, we get

\[(z - (1 - 2n)\epsilon)G_{ij} = (1 - 2n)\delta_{ij} + \frac{1}{2}(1 - 2n)\sum_l J_{il}F_{lj}\]  \hfill (23)

In the same way, we obtain:

\[(z - (1 - 2n)\epsilon)F_{ij} = -\frac{1}{2}(1 - 2n)\sum_l J_{il}G_{lj}\]  \hfill (24)

These two equations are closed and yield the Green functions. This approximation is similar to the first-order Hubbard approximation of the electronic Hubbard model. Since \(S_i^z = 1/2 - n_i\), it is clear that the above result is equivalent to results obtained previously for the spin model \([1, 2]\). The Green functions are given by

\[G_k = (1 - 2n)[z + (1 - 2n)\epsilon]/[z^2 - \epsilon^2(1 - 2n)^2(1 - r_k^2)]\]

\[F_k = -(1 - 2n)^2\epsilon r_k/[z^2 - \epsilon^2(1 - 2n)^2(1 - r_k^2)]\]  \hfill (25)

The self-consistent equation to determine the \(n\) is given by

\[
\frac{1}{2} = \left(\frac{1}{2} - n\right)\frac{1}{N}\sum_k \frac{1}{\sqrt{1 - r_k^2}} \coth \frac{\omega_k}{2T}
\]  \hfill (26)

where \(\omega_k = (\frac{1}{2} - n)JZ\sqrt{1 - r_k^2}\). In three dimensions we get for the zero-temperature sublattice magnetization, \(S_0 = 0.4325\), and the Néel temperature is: \(T_N = 0.989J\).

The sublattice magnetization as a function of \(T\) is shown in Figure 3. The Néel temperature is better than that of the conventional spin wave theories because the high temperature expansion result is \(0.951J\) \([20]\). For small temperature \(T\) we obtain

\[\langle S^z \rangle = S_0 - \eta(T/J)^2\]

When temperature tends to \(T_N\), the sublattice magnetization has the following asymptotic expression.

\[\langle S^z \rangle \propto \sqrt{1 - T/T_N}, \quad T_N = JZ/4P\]  \hfill (27)

The sublattice magnetization as a function of temperature is shown in Figure 3. The results of the linear spin wave theory and a nonlinear spin wave theory are also presented for comparison. The nonlinear theories produce an unphysical first order transition at \(T = 1.11J\) in three dimensions \([23]\), being similar to the FM case. The result from \([20]\) is best in the whole temperature region. In two dimensions \(T_N = 0\)
and the zero-temperature sublattice magnetization is equivalent to 0.3587, being larger than the results of the spin wave theories and a series expansion result in which the spin wave behavior was used in their extrapolation. But it is consistent to a Monte Carlo result 0.34 ± 0.01. A Green function Monte Carlo result is 0.31 ± 0.02. In one dimension the average sublattice magnetization is zero even at zero temperature. This is consistent with the Mermin-Wagner theorem. It is clear that the inter-site coupling modifies the spectra and the $U$ term reduces the spectral weight. Without these two terms, we should get the linear spin wave theory. But the $U$ term is necessary to remove the unphysical states. The linear spin wave theory overestimated the spectral weight by about thirty percent in terms of a study on the sum rules and spin excitations of the quantum AFM Heisenberg models.

The $U$ term does not contribute to the ground state energy. Our ground state energies in two and three dimensions are $E_{0}^{AFM}/\epsilon N = -0.327$ and $-0.297$, respectively. The ground state energies are a little higher than the existing results of spin wave theories. On the other hand, the spectral factor $f = 1 - 2n$ is less than 1. Therefore, some improvement to the ground state is desirable.

The AFM ground states in a relaxed decoupling: To improve our approximation, we relax the constraint of the decoupling by permitting the decoupling of the operators on a site without changing the position of the operator product in the on-site $U$ level hierarchy. In this approximation, the inter-site correlation functions enter the spectral renormalization factor $f$ so that we obtain the following nonlinear equation set of two variables at zero temperature.

\[
\frac{1}{2} = \left(\frac{1}{2} - n\right) \frac{1}{N} \sum_{k} \frac{1}{\sqrt{1 - r_{k}^{2}}}
\]

\[
\xi = -\left(\frac{1}{2} - n\right) \frac{1}{N} \sum_{k} \frac{r_{k}^{2}}{\sqrt{1 - r_{k}^{2}}}
\]

Now our magnon spectrum is defined by $\omega_{k} = \frac{1}{2} JZ f \sqrt{1 - r_{k}^{2}}$ and our spectral factor is defined by $f = 1 - 2n - 2\xi$. For the ground state we obtain the same $n$ and $\xi$ as the above. Therefore we obtain $(E_{0}^{AFM}/\epsilon N, S_{0}, f) = (-0.3106, 0.4325, 1.084)$ in
three dimensions and \((-0.345, 0.3587, 1.113)\) in two dimensions. The renormalization factors are acceptable and the ground state energies are lower than those of the spin wave theories\([13, 14, 18, 8, 1]\) and others available\([22, 23, 21, 4, 2]\). The details are summarized in Table 1. The ground state energies, $E_0$, in Table 1 are given in units of $JdN$ where $d$ is the dimension.

5 Discussion and summary

We have studied the half-spin strong-coupling magnon hamiltonians without any unphysical states in a simple Hubbard-like decoupling approximation. For higher spins the strong-coupling hamiltonians can be treated similarly. Following the routine described by Fulde\([27]\), we can also treat our magnon hamiltonians by means of the projection method. In the above simple decoupling approximation we obtain the same sublattice spins as that obtained directly from the original spin hamiltonians, but our spectral renormalization factors at zero temperature are improved substantially and our ground state energies are lower than those of existing approximations. From Figure 2 and Figure 3 it is clear that our strong-coupling magnon hamiltonians in the simple decoupling approximation improve the conventional spin wave theories. The nonlinear spin wave theories produce unphysical first-order transitions. There have been many versions for the nonlinear spin wave theory, but the main feature and drawback is similar in all these versions. But our strong-coupling magnon theories do not lead to such unphysical behavior, because all unphysical states in the Hilbert space have been removed, and is, therefore, advantageous over the original spin model and the conventional magnon hamiltonian. Compared to Ref.\([19]\), where the introduction of a similar strong-coupling U-term was suggested, we presented here a formulation, which works for ferro- and antiferromagnetic Heisenberg models of any spin $s$, and we applied for the first time a Green function decoupling approximation to this model and could calculate quantities like the order parameter (magnetization), the critical temperature $T_c$, etc.
In summary, we introduce an infinite-$U$ term into the Holstein-Primakoff magnon hamiltonian of quantum Heisenberg magnetic models of any spin $s$. This term rigorously removes the unphysical magnon states on every site and at the same time automatically truncates the expansion of the square root $\sqrt{1 - n_i/s}$. The resultant magnon hamiltonians are accurately equivalent to the original spin hamiltonians. We have studied the on-site $U$ levels and their implication on the spin physics. Within a simple decoupling approximation we obtain physically reasonable results for the FM magnetization and AFM sublattice magnetization in agreement with existing results obtained for the original spin model. But we obtain lower ground-state energies than those of the previous theories because our hamiltonians are composed of the bosonic magnon operators and free of unphysical states.

Table and Figure Captions

Table 1: The AFM ground state energy and sublattice spin available in various approximations of quantum Heisenberg models of half-spin. The $E_0$'s are in unit of $Jd$. LSW: the linear spin wave theory; NLSW: the nonlinear spin wave theory; Series+SW: the series expansion method in which some spin wave behavior was used in their extrapolation; MC: the Monte Carlo; GFMC: Green function Monte Carlo; Projection: projection method by spin operators; SGFMF: spin Green function mean-field; This work: The result of this paper.

Fig 1: left: On-site $U$ levels in the case of the half spin. At the ground level there are only $|0\rangle$ and $a_i^\dagger|0\rangle$. right: On-site $U$ levels in the case of the unit spin. At the ground level there are only $|0\rangle$, $a_i^\dagger|0\rangle$, and $a_i^{12}|0\rangle$.

Fig 2: 3D magnetization of the FM model as function of temperature. The solid line is for the approximation in this paper; the dashed line for nonlinear spin wave theories; the dotted line for linear spin wave theory. The $T_c$'s are 0.989$J$, 0.98$J$, and 1.71$J$, respectively. But a high temperature expansion result is 0.889$J$. The transition for the nonlinear spin wave theory is of first order.

Fig 3: 3D sublattice magnetization of the AFM model as function of temperature. The solid line is for the approximation in this paper; the dashed line for nonlinear spin wave theories; the dotted line for linear spin wave theory. The $T_N$'s are 0.989$J$, 1.107$J$, and 1.70$J$, respectively. But a high temperature expansion result is 0.951$J$. The transition for the nonlinear spin wave theories is of first order.
