Abstract
The $L_2$-minimax risk in Sobolev classes of densities with non-integer smoothness index is shown to have an analog form to that in integer Sobolev classes. To this end, the notion of Sobolev classes is generalized to fractional derivatives of order $\beta \in \mathbb{R}^+$. A minimax kernel density estimator for such a classes is found. Although there exists no corresponding proof in the literature so far, the result of this article was used implicitly in numerous papers. A certain necessity that this gap had to be filled, can thus not be denied.

Keywords: exact asymptotics, fractional derivative, Fourier transform, minimax risk, Sobolev classes
Mathematical Subject Classification: 62C20

1 Introduction
When trying to describe the goodness of an estimator, minimax performance is one optimality criterium possible to be consulted. The minimax risk of density estimators can be regarded in various settings, e.g. we differentiate between the local risk in a single point and the integrated risk over the whole curve. Several loss functions have been under consideration, such as absolute, quadratic and supremum norm, Hellinger and Kullback-Leibler distance. But exact asymptotics is up to now limited to a few special cases: to supremum risk in Hölder classes, and to mean integrated square error (MISE) in analytical and in Sobolev classes.

The latter has been examined for quite a while since in 1983, Efroimovich and Pinsker completed the asymptotic minimax rate of the lower bound of MISE (Samarow [8]) by the still lacking asymptotically exact constant, using tools that are common in information theory. The results were enhanced and new methods of proof found by Golubev [3] and [4], Golubev, Levit [6] and Schipper [10]. Sobolev classes are classes of $L_2$-integrable functions, in the present problem densities, for which smoothness is measured through the $L_2$-norm of their $\beta^{th}$ derivative, $\beta \in \mathbb{N}$.

$$S_\beta(L) = \left\{ f \in L_2 \mid \int \left( f^{(\beta)}(x) \right)^2 dx \leq L \right\}, \quad L < \infty$$

Nowadays it is well known that

$$\inf_{f_n} \sup_{f \in S_\beta(L)} n^{2\beta+1} \mathbb{E}^f \| \hat{f}_n - f \|^2_2 = \gamma(\beta,L) \left( 1 + o(1) \right)$$

be found by means of the van Trees inequality. The Bayesian risk over a least favorable

$\gamma(\beta, L) = (2\beta + 1) \left( \frac{\pi (2\beta + 1)(\beta + 1)}{\beta} \right)^{-\frac{\beta}{2\beta + 1}} L^{-\frac{1}{2\beta + 1}}$

is Pinsker's constant. Estimators attaining minimax rates of convergence have been studied in abundance, e.g. kernel estimators, but also wavelet estimators and a wide range of others. More care has to be taken when envisaging asymptotically exact minimax estimators.

However, the characterization of the smoothness of a given density function is incomplete when just assigning it to some $S_\beta(L)$, $\beta \in \mathbb{N}$. Recalling the Sobolev criterion,

$$ L \geq \int \left( f^{(\beta)}(x) \right)^2 dx = \frac{1}{2\pi} \int |\omega^\beta \hat{f}(\omega)|^2 d\omega, $$

we immediately observe that $S_\beta(L)$ contains densities which do not lie in $S_{\beta + 1}$, although for suitably chosen $L' < \infty$ and $\varepsilon < 1$, they certainly do satisfy $\frac{1}{2\pi} \int |\omega^{\beta + \varepsilon} \hat{f}(\omega)|^2 d\omega \leq L'$.

The present article is interested in the question of whether the minimax risk can also be calculated for such generalized Sobolev classes. Corresponding claims are implicit in a number of recent papers, yet their proofs cover but the entire case. For our purpose we will employ the concept of the so-called fractional derivative after Riemann and Liouville, thoroughly discussed in Samko [4]:

$$ f^{(\beta)}(x) = \frac{d^\beta}{dx^\beta} f(x) = \frac{1}{\Gamma([\beta] - \beta)} \frac{d^{[\beta]}}{dx^{[\beta]}} \int t^{\beta - [\beta]} f(x + t) dt $$

with $[\beta]$ the smallest integer greater than the positive real number $\beta$. For $\beta \in \mathbb{N}$, $f^{(\beta)}$ is the $\beta$th derivative of $f$, for $\beta \in \mathbb{R}^+ \setminus \mathbb{N}$ it is the $\beta$th fractional derivative of $f$ (Samko [4], p. 137). In case $f^{(\beta)}$ is continuous and $L_1$-integrable, then $f^{(\beta)}(\omega) = (-i\omega)^\beta \hat{f}(\omega)$. The other way around, if $(-i \cdot i)^\beta \hat{f}$ is $L_1$- or $L_2$-integrable, the inverse transform from the Fourier into the time domain exists and for our purpose we define:

$$ f^{(\beta)}(x) := \frac{1}{2\pi} \int (-i\omega)^\beta \hat{f}(\omega) e^{-ix\omega} d\omega $$

existence and uniqueness of the $\beta$th fractional derivative of $f$ follow thus from $\frac{1}{2\pi} \int |\omega^\beta \hat{f}(\omega)|^2 d\omega \leq L$, and Parseval's equality gives $\int (f^{(\beta)}(x))^2 dx = \frac{1}{2\pi} \int |\omega^\beta \hat{f}(\omega)|^2 d\omega$.

Adopting the idea of Schipper [10], we find upper and lower bounds for the asymptotic minimax risk in $S_\beta(L)$, $\beta > 1/2$, which are then shown to converge towards each other. Thereby it will be verified that the minimax risk is determined by $\gamma(\beta, L)$, where $\gamma(\beta, L)$ is an analogue of Pinsker's constant. A minimax kernel function for kernel density estimation is obtained as a byproduct from the calculation. On benefit of our a statement, it is for instance possible to show the asymptotically exact minimax- adaptivity of non-parametric estimation procedures such as the recently proposed Stein's blockwise estimator for densities (Rigollet [7]) and the cross-validation kernel choice for density estimation (Dalelane [1]).

The calculation of the upper bound in Schipper [10] actually holds for both entire and non-entire smoothness indices, so Schipper's Theorem 3 (Math. Meth. of Statistics (1996), Vol. 5 No. 3, page 258-260) applies directly. To show the lower bound in Section 2, we replace original problem of estimating a curve by the problem of estimating a finite-dimensional parameter $\theta$ (of increasing dimension). A lower bound for the risk of such an estimator may be found by means of the van Trees inequality. The Bayesian risk over a least favorable parametric family of densities $\mathcal{F}_\Theta$, and a least favorable prior distribution $\Lambda$ on the space of finite-dimensional parameters $\Theta$, such that $f_\theta \in S_\beta(L)$ with a high probability, provides us
with a lower bound for the minimax risk on $S_\beta(L)$. It is exactly this gap in the literature: $f_\theta$ asymptotically in $S_\beta(L)$ for $\beta \notin \mathbb{N}$, which we have been able to close in the present paper. Although the demonstrations follow in general the same lines as Schipper [10], the least favorable family of densities had to be constructed in a different way. The proof of the essential property (Theorem 2) applies Riemann-Liouville calculus along with approximations in the Fourier domain and is not similar to Schipper [10].

The result for the lower bound can be considered as a special case of the theorem in Golubev [5], who yields lower bounds for the quadratic risk of non-parametric estimation problems in a variety of elliptic density classes via Local Asymptotic Normality. Unfortunately the proof in Golubev [5] is heavily abbreviated (the proof of a claim corresponding to our Theorem 2 is actually omitted) and not easy to retrace. We hope that by our detailed proof, we are able to somehow enlighten the complicated matters.

2 Minimax bounds

Let $X_1, \ldots, X_n$ be i.i.d. random variables with common density function $f$ and let $\tilde{f}_n$ be an arbitrary estimator for $f$ depending but on the sample.

**Theorem 1** (see Schipper [10] Theorem 3) Let $S_\beta(L)$ be the Sobolev class of those $L_2$-integrable densities, which satisfy

$$\frac{1}{2\pi} \int |\omega^\beta \hat{f}(\omega)|^2 d\omega \leq L$$

for some constants $\beta > 0$ and $L < \infty$. Then it holds, that

$$\inf_{\tilde{f}_n} \sup_{S_\beta(L)} n^{\frac{2\beta}{2\beta+1}} E_f \|\tilde{f}_n - f\|_2^2 \leq \gamma(\beta, L)$$

The bound is maintained by a kernel estimator with the minimax kernel $K_\beta$, that is the inverse Fourier transform of $\hat{K}_\beta(\omega) = (1 - e_{\min}(L) \cdot |\omega|^{\beta})_+$ with $e_{\min} = \left(nL(2\beta+1)(\beta+1)\right)^{-\beta/(2\beta+1)}$.

Generally speaking, the derivation of the lower bound proceeds similarly to Schipper [10] (Subsection 4.1, page 262-268). However it is not the same, and so we give a little more detail. The following steps lead to the desired result, which can partly be effected analogously to Schipper [10], partly new proofs had to found:

1) Construction of a least favorable parametric family of densities $F_\Theta$, proof that the elements of $F_\Theta$ are contained in an $\varepsilon$-neighborhood of the considered Sobolev class $S_\beta(L)$. Both our center function of $F_\Theta$ and our perturbation functions had to be constructed in a distinct way to Schipper [10], whereas the parameter set $\Theta$ is the same. The proof of our Theorem 2 is different to that of Schipper’s corresponding lemmata (Lemma 1 through 4).

2) Definition of a least favorable prior distribution $\Lambda$ on the parameter set $\Theta$, proof that under $\Lambda$ the elements of $F_\Theta$ are contained in $S_\beta(L)$ itself with high probability. This time, Schipper’s distribution $\Lambda$ and his proof (Lemma 5, p. 266-267) are possible to transfer to our context.

3) Main approximation of the lower bound via the Bayes risk over $F_\Theta$ with respect to $\Lambda$ by means of the van Trees inequality. Again the proof of Schipper’s Proposition 2 (p. 267-268) resembles our demonstration.

The problem of searching a lower bound for the minimax risk over the Sobolev class $S_\beta(L)$, can be reverted to a parametric subset of $S_\beta$. Whether the minimax risk over the subclass...
prove that

These perturbations will be weighted by factors $f$ for all $\beta < \infty$, so that for every $\beta < \infty$. Let $g_A$ be the indicator function on $[-A + 1/2, A - 1/2]$ times the factor $\frac{1}{2A - 1}$, i.e.

$$g_A(x) := \frac{1}{2A - 1} I([-A + 1/2, A - 1/2])(x).$$

Then $f_0 * g_A$ is a symmetric density within $\mathcal{S}$, that takes the constant value $\frac{1}{2A - 1}$ on $[-A + 1, A - 1]$, and decreases smoothly towards 0 on $[A - 1, A]$ and $[-A, -A + 1]$. In order to constitute a sufficiently difficult estimation problem departing from this very smooth density, let us add some perturbation functions to $f_0 * g_A$:

$$\varphi_k(x) := \begin{cases} \frac{1}{\sqrt{A}} \cos \frac{k\pi}{A} I([-A,A])(x), & k > 0 \\ \frac{1}{\sqrt{A}} \sin \frac{k\pi}{A} I([-A,A])(x), & k < 0 \end{cases}$$

These perturbations will be weighted by factors $\theta_k$, where $\theta = (\ldots, \theta_{-2}, \theta_{-1}, \theta_1, \theta_2, \ldots)$ is (asymptotically) in the set:

$$\Theta_A(L) := \left\{ \theta \in \mathbb{R}^\infty \middle| \sum_{k \neq 0} |\theta_k| \leq A^{-2\beta + 1} \text{ and } \sum_{k \neq 0} \theta_k^2 \left( \frac{k\pi}{A} \right)^{2\beta} \leq 4A^2L \right\}$$

The set $\{f_\theta | \theta \in \Theta_A(L)\}$ will from now on be the family of densities under consideration.

$$f_\theta(x) := \frac{1}{b(\theta)} f_0 * g_A(x) \left( 1 + \sum_{k \neq 0} \theta_k \varphi_k(x) \right),$$

where $b(\theta)$ is the normalizing constant. We cannot prove that $\{f_\theta | \theta \in \Theta_A(L)\} \subseteq \mathcal{S}_\beta(L)$, but instead that for all $\varepsilon > 0$ there exists an $A_\varepsilon < \infty$, so that for every $A \geq A_\varepsilon$ the following holds: $\sup_{\theta \in \Theta_A(L)} \|f_\theta^{(j)}\|_2^2 \leq L + \varepsilon$.

**Theorem 2** Let $f_\theta$ and $\Theta_A(L)$ be defined as above. Then, as $A \longrightarrow \infty$:

$$\sup_{\Theta_A(L)} \|f_\theta^{(j)}\|_2^2 = L + o(1)$$

This theorem is the main assertion of our paper. Filling the gap in the hitherto existing literature, it enables us to go on proving the minimax bound for non-integer Sobolev classes. Its cumbersome and unpleasantly lengthy proof is to be found in Section 5.

The next step leading to the lower bound requires the definition of a prior distribution $\Lambda$, which is done accordingly to [1], so as to yield a parameter $\theta$ of finite dimension: Let $\varepsilon > 0$, $W > 0$ and $\sigma_k^2 > 0$

$$\lambda(\theta) = \prod_{0 < |k| < W} \lambda_k(\theta_k) \prod_{|k| \geq W} \delta_0(\theta_k),$$

4
where $\delta_0(.)$ is the Dirac function on 0, and for $|k| < W$: $\lambda_k(\theta_k)$ are absolutely continuous densities with $E\theta_k^2 = \sigma_k^2$, $\theta_k^2 \leq G^2\sigma_k^2$ (A-f.s.) for some $G < \infty$, and the Fisher information $I_k := \int \frac{\lambda_k^2(\theta_k)}{\lambda_k(\theta_k)} d\theta_k \leq (1 + \varepsilon)\sigma_k^{-2}$ (with respect to the translation group $\{\lambda_k(-u)|u \in \mathbb{R}\}$). (These conditions are satisfied, for example, by independent bounded, zero mean random variables $\sigma_k \xi_k$, $|k| < W$, with $|\xi_k| < G$, $E\xi_k^2 = 1$ and the Fisher-information of the density of $\xi_k$ smaller than $1 + \varepsilon$.) Let us set

$$W = \frac{A}{\pi} \left( \frac{L(1 - \varepsilon)n(2\beta + 1)(\beta + 1)\pi}{\beta} \right)^{\frac{1}{2\beta + 1}} \quad (10)$$

$$\sigma_k^2 = \frac{4A}{n} \left( \frac{|W|^\beta}{k} - 1 \right)$$

As $W$ grows with $n \to \infty$, the dimension of the parameter $\theta$ will tend to infinity, allowing for more and more perturbation functions $\varphi_k$ in the definition of $f_\theta$. At the end of Section 3 it will be shown that $\sigma_k^2$ and $W$ of this form approximately maximize the lower bound of the minimax risk for the prior distribution $\Lambda$.

Since $\Lambda$ is not supported on $\Theta_A(L)$, we will have to show that at least the probability of $\theta \in \Theta_A(L)$ grows with $n \to \infty$:

First consider that $\lambda$ has a bounded support, $|\theta_k| \leq G\sigma_k$ for $|k| < W$, and else $\theta_k = 0$. With the above construction of $\sigma_k^2$ and $W$, letting $A \sim \ln n$, condition $\sum |\theta_k| \leq A^{-2\beta + 1}$ is fulfilled for $n$ sufficiently large. Lemma 1 takes care of $\sum \theta_k^2 \left( \frac{|\xi_k|}{n} \right)^{2\beta} \leq 4A^2L$.

**Lemma 1** For the prior distribution $\Lambda$ defined above, with $W$ and $\sigma_k^2$ as in (10), it holds that for $n \to \infty$:

$$P_\Lambda \left( \theta \not\in \Theta_A(L) \right) = o(n^{-1})$$

This lemma corresponds to Lemma 5 in Schipper [10], p. 266. Its proof is exactly the same (p. 266-267) and we abstain from quoting it here (also see Dalelane [1] for more details).

**Theorem 3** For $L < \infty$, $\beta > 1/2$ and $\gamma(\beta, L)$ equal to Pinsker’s constant we have:

$$\liminf_{n \to \infty} \inf_{f_n} \sup_{f \in \mathcal{S}_\beta(L)} n^{\frac{2\beta}{2\beta + 1}} E_f ||f_n - f||_2^2 \geq \gamma(\beta, L)$$

**Proof** Let us at first reduce the supremum of the risk by restricting the set of density functions. According to Theorem 2 we know that for $A \sim \ln n$, $\lim_{A \to \infty} \{f_\theta | \theta \in \Theta_A(L)\} \subseteq \mathcal{S}_\beta(L)$.

$$\liminf_{n \to \infty} \inf_{f_n} \sup_{f \in \mathcal{S}_\beta(L)} E_f ||f_n - f||_2^2 \geq \liminf_{n \to \infty} \inf_{f_n} \sup_{f \in \Theta_A(L)} E_{f_\theta} ||f_n - f_\theta||_2^2 \quad (11)$$

For any fixed $A$, we find a lower bound for the supremum over $\Theta_A(L)$ through the Bayesian risk with respect to $\Lambda$.

$$\inf_{f_n} \sup_{f \in \Theta_A(L)} E_{f_\theta} ||f_n - f_\theta||_2^2 \geq \inf_{f_n} \int_{\Theta_A(L)} E_{f_\theta} ||f_n - f_\theta||_2^2 d\Lambda(\theta) \quad (12)$$
Furthermore, because of orthonormality

\[ \langle \theta_k \varphi_k \rangle = \sum \theta_k^2 \leq \sum |\theta_k| \leq A^{-2\beta+1}, \]

so we can derive, for all \( \theta \in \Theta_A(L) \):

\[
\|f_{\theta}\|_2 = \frac{1}{b(\theta)} \|f_0 * g_A \left( 1 - \sum_{k \neq 0} \theta_k \varphi_k \right) \|_2 \\
\leq \frac{1}{b(\theta)} \max f_0 * g_A \|I_{[-A,A]} + \sum \theta_k \varphi_k \|_2 \\
\leq \frac{\text{const.}}{\sqrt{A}} =: \frac{1}{\sqrt{A_0}}
\]

Because the set of all densities with \( \|f\|_2 \leq 1/A_0 \) is convex, we may in (13) also restrict the set estimators to \( \|\tilde{f}_n\|_2^2 \leq 1/A_0 \) without increasing the supremum.

\[
\inf_{\tilde{f}_n} \int_{\Theta_A(L)} E_{f_0} \|\tilde{f}_n - f_{\theta}\|_2^2 \, d\Lambda(\theta) = \inf_{\|\tilde{f}_n\|_2^2 \leq A_0^{-1}} \int_{\Theta_A(L)} E_{f_0} \|\tilde{f}_n - f_{\theta}\|_2^2 \, d\Lambda(\theta) = \frac{1}{A_0} \inf_{\|\tilde{f}_n\|_2^2 \leq A_0^{-1}} \int_{\Theta_A(L)} E_{f_0} \|\tilde{f}_n - f_{\theta}\|_2^2 \, d\Lambda(\theta) = \frac{1}{A_0} P_\lambda(\theta \notin \Theta_A(L))
\]

Due to \( \|f_{\theta}\|_2^2 \leq A_0^{-1} \) and \( \|\tilde{f}_n\|_2^2 \leq A_0^{-1} \) it holds in (14) that \( \|\tilde{f}_n - f_{\theta}\|_2^2 \leq 4A_0^{-1} \). In (15) we return to the complete set of estimators.

Since \( f_{\theta} \) has bounded support, i.e. \([-A,A]\), it is equivalent, as regards the quadratic risk, either to estimate the function \( f_{\theta} \) in the time domain or its Fourier coefficients. \( (\hat{f}_{\theta}(0) = 1 \) is known)

\[
E_{\lambda}E_{f_0} \|\tilde{f}_n - f_{\theta}\|_2^2 = \frac{1}{A_0} \sum_{\kappa \neq 0} \left( \hat{f}_n \left( \frac{\kappa \pi}{A} \right) - \hat{f}_{\theta} \left( \frac{\kappa \pi}{A} \right) \right)^2 \\
= E_{\lambda}E_{f_0} \frac{1}{A_0} \sum_{\kappa \neq 0} \text{Re}^2 \left( \hat{f}_n \left( \frac{\kappa \pi}{A} \right) - \hat{f}_{\theta} \left( \frac{\kappa \pi}{A} \right) \right) + \text{Im}^2 \left( \hat{f}_n \left( \frac{\kappa \pi}{A} \right) - \hat{f}_{\theta} \left( \frac{\kappa \pi}{A} \right) \right) \\
= E_{\lambda}E_{f_0} \frac{1}{A_0} \sum_{\kappa \neq 0} \left( \text{Re} \tilde{f}_n \left( \frac{\kappa \pi}{A} \right) - \text{Re} \tilde{f}_{\theta} \left( \frac{\kappa \pi}{A} \right) \right)^2 + \left( \text{Im} \tilde{f}_n \left( \frac{\kappa \pi}{A} \right) - \text{Im} \tilde{f}_{\theta} \left( \frac{\kappa \pi}{A} \right) \right)^2
\]

The van Trees inequality (Gill, Levit) may now be applied on every single summand. For technical reason, the real parts are derived with respect to \( \theta_{|\kappa|} \), while the imaginary ones are derived with respect to \( \theta_{-|\kappa|} \).

\[
E_{\lambda}E_{f_0} \left[ \text{Re} \tilde{f}_n \left( \frac{\kappa \pi}{A} \right) - \text{Re} \tilde{f}_{\theta} \left( \frac{\kappa \pi}{A} \right) \right]^2 \geq \frac{E_{\lambda}^2 \left[ \partial \text{Re} \tilde{f}_{\theta} \left( \frac{\kappa \pi}{A} \right) / \partial \theta_{|\kappa|} \right]}{nE_{\lambda}I_{f_0}(\theta_{|\kappa|}) + I_{|\kappa|}}
\]

\[
E_{\lambda}E_{f_0} \left[ \text{Im} \tilde{f}_n \left( \frac{\kappa \pi}{A} \right) - \text{Im} \tilde{f}_{\theta} \left( \frac{\kappa \pi}{A} \right) \right]^2 \geq \frac{E_{\lambda}^2 \left[ \partial \text{Im} \tilde{f}_{\theta} \left( \frac{\kappa \pi}{A} \right) / \partial \theta_{-|\kappa|} \right]}{nE_{\lambda}I_{f_0}(\theta_{-|\kappa|}) + I_{-|\kappa|}}
\]
where we denote $I_{f_{\theta}}(\theta_{\kappa}) = \int (\partial f_{\theta}(x)/\partial \theta_{\kappa})^2 \, dx$. $I_{\kappa}$ is the “Fisher information” of $\lambda_{\kappa}$ and by construction $\leq (1 + \varepsilon)\sigma_{\kappa}^2$ for $|\kappa| < W$ and $= \infty$ for $|\kappa| \geq W$, respectively. Hence all summands with $|\kappa| \geq W$ vanish from the sum. Approximations for $I_{f_{\theta}}(\theta_{\kappa})$, $\partial \text{Re } f_{\theta}(\frac{\kappa\pi}{A})/\partial \theta_{|\kappa|}$ and $\partial \text{Im } f_{\theta}(\frac{\kappa\pi}{A})/\partial \theta_{-|\kappa|}$ are available from

**Lemma 2** For $A \rightarrow \infty$:

$$I_{f_{\theta}}(\theta_{\kappa}) = \frac{1 + o(1)}{2A} \quad \text{and} \quad \frac{\partial \text{Re } f_{\theta}(\frac{\kappa\pi}{A})}{\partial \theta_{|\kappa|}} = \frac{1 + o(1)}{2\sqrt{A}} \quad \text{and} \quad \frac{\partial \text{Im } f_{\theta}(\frac{\kappa\pi}{A})}{\partial \theta_{-|\kappa|}} = \frac{1 + o(1)}{2\sqrt{A}}$$

with $o(1)$ independent of $\kappa$ and $\theta_{\kappa}$. The proof is postponed to Section 5. From (15) completed by (14), the van Trees approximation (17) and Lemma 2 we thus have:

$$\inf_{f_n} E_\lambda E_{f_{\theta}} \|\tilde{f}_n - f_{\theta}\|^2 = \inf_{f_n} E_\lambda E_{f_{\theta}} \frac{1}{2A} \sum_{\kappa \neq 0} \left|\tilde{f}_n \left(\frac{\kappa\pi}{A}\right) - f_{\theta} \left(\frac{\kappa\pi}{A}\right)\right|^2$$

$$\geq \frac{1}{2A} \sum_{\kappa \neq 0} \left(\frac{1 + o(1)}{2\sqrt{A}}\right)^2 + \frac{1}{n} \left(\frac{1 + o(1)}{2\sqrt{A}}\right)^2 \sum_{0 < |\kappa| < W} \frac{1}{n + 2A\sigma^2}$$

All sums obtained from $W$ and $\sigma^2$ through (18), i.e. from a prior distribution $\Lambda$ satisfying Lemma 1, are thus lower bounds of the minimax risk.

What we are searching for is a bound as large as possible, we hence maximize (18) subject to the constraint $\sum \sigma^2 (\frac{\kappa\pi}{A})^{2\beta} \leq (1 - \varepsilon)4A^2L$, such that $P(\theta \neq \Theta\lambda(L)) = o(n^{-1})$ remains valid. The solution to this problem is $W$ and $\sigma^2$ from (14). The maximum in (18) can be approximated as follows:

$$\frac{1}{2A(1 + \varepsilon)n} \sum_{0 < |\kappa| < W} \left|\frac{W}{\kappa}\beta - 1\right| \left|\frac{\kappa}{W}\right|^\beta$$

$$= \frac{1}{A(1 + \varepsilon)n} \sum_{0 < \kappa < W} \left(1 - \left(\frac{\kappa}{W}\right)^\beta\right)$$

$$= \frac{A}{A(1 + \varepsilon)n} \frac{\beta}{\beta + 1} W(1 + o(1))$$

$$= \frac{(2\beta + 1)}{\beta} \frac{1 + o(1)}{\beta + 1} W^\beta L^{\frac{2\beta}{2\beta + 1}} (1 - \varepsilon)^{\frac{2\beta + 1}{2\beta + 1}} (1 + o(1))$$

$$= n^{\frac{2\beta}{2\beta + 1}} \gamma(\beta, L) \left(1 + o(1)\right)$$

(19)

Combining (11) with (12), (13), (18) and (19), we obtain the required result:

$$\lim_{n \to \infty} \inf_{f_n} \sup_{S_{\beta}(L)} n^{\frac{2\beta}{2\beta + 1}} E_f \|\tilde{f}_n - f\|^2 \geq \gamma(\beta, L)$$
3 Remaining Proofs

Proof of Theorem 2 For \( f_\theta \) defined in equation (8), it holds that

\[
\|f_\theta^{(b)}\|_2 = \frac{1}{b(\theta)} \left\| (f_0 * g_A)^{(\beta)} + \left( f_0 * g_A \sum_{k \neq 0} \theta_k \varphi_k \right)^{(\beta)} \right\|_2 \\
\leq \frac{1}{b(\theta)} \left\| (f_0 * g_A)^{(\beta)} \right\|_2 + \frac{1}{b(\theta)} \left\| \left( f_0 * g_A \sum_{k \neq 0} \theta_k \varphi_k \right)^{(\beta)} \right\|_2
\]

\( b(\theta), \left\| (f_0 * g_A)^{(\beta)} \right\|_2 \) and \( \left\| (f_0 * g_A \sum_{k \neq 0} \theta_k \varphi_k)^{(\beta)} \right\|_2 \) are then considered one by one. Remember definition (3): \( \varphi_k(x) = A^{-1/2} \cos(\pi k / A) I(|x| \leq A) \) for \( k > 0 \), and the same with sine for \( k < 0 \). Take first the normalizing constant \( b(\theta) \):

\[
b(\theta) = \int_{-A}^{A} f_0 * g_A(x) \left( 1 + \sum_{k \neq 0} \theta_k \varphi_k(x) \right) dx
\]

\[
= 1 + \sum_{k > 0} \theta_k \int_{-A}^{A} f_0 * g_A(x) \varphi_k(x) dx
\]

\[
= 1 + \sum_{k > 0} \theta_k \int_{-A}^{A} f_0 * g_A(x) \frac{1}{\sqrt{A}} \cos \frac{k \pi x}{A} dx + \sum_{k < 0} \theta_k \int_{-A}^{A} f_0 * g_A(x) \frac{1}{\sqrt{A}} \sin \frac{k \pi x}{A} dx
\]

\[
= 1 + \sum_{k > 0} \theta_k \int_{-A}^{A} f_0 * g_A(x) \frac{1}{\sqrt{A}} \cos \frac{k \pi x}{A} dx + 0
\]

\[
= 1 + \frac{1}{\sqrt{A}} \sum_{k > 0} \theta_k \left[ \int_{-A}^{A} \frac{1}{2A - 1} \cos \frac{k \pi x}{A} dx - 2 \int_{A-1}^{A} \left( \frac{1}{2A - 1} - f_0 * g_A(x) \right) \cos \frac{k \pi x}{A} dx \right]
\]

\[
= 1 + \frac{1}{\sqrt{A}} \sum_{k > 0} \theta_k \left[ 2 \int_{A-1}^{A} \left( \frac{1}{2A - 1} - f_0 * g_A(x) \right) \cos \frac{k \pi x}{A} dx \right]
\]

For the second term on the right-hand side we have:

\[
\frac{2}{\sqrt{A}} \left| \sum_{k > 0} \theta_k \int_{A-1}^{A} \left( \frac{1}{2A - 1} - f_0 * g_A(x) \right) \cos \frac{k \pi x}{A} dx \right| \leq \frac{2}{\sqrt{A}} \sum_{k > 0} \left| \theta_k \right| \int_{A-1}^{A} \frac{1}{2A - 1} \left| \cos \frac{k \pi x}{A} \right| dx
\]

\[
\leq \frac{2}{\sqrt{A(2A - 1)}} \sum_{k > 0} \left| \theta_k \right|
\]

\[
\leq \frac{1}{\sqrt{A(A - 1/2)}} A^{-2\beta + 1},
\]

so that for \( \beta > 1/2 \) and \( A \) sufficiently large, it follows that

\[
1 - A^{-3/2} \leq b(\theta) \leq 1 + A^{-3/2}
\]

(\( f_0 * g_A)^{(\beta)} \) is integrable in \( L_2 \). So instead of the \( L_2 \)-norm of \( f_0 * g_A \) in the time domain, by Parseval’s equality we may as well study the \( L_2 \)-norm of its Fourier transform.

\[
\left\| (f_0 * g_A)^{(\beta)} \right\|^2_2 = \int_{-A}^{A} \left| (f_0 * g_A)^{(\beta)}(x) \right|^2 dx
\]
As usual, little knowledge about fractional derivatives. For two sufficiently regular functions \(f, g\), the Leibnitz formula takes the following form:

\[
\sum_{i=0}^{\infty} \binom{\beta}{i} f^{(i)} \cdot g^{(\beta-i)}
\]

where \(\binom{\beta}{i}\) an analogue to the binomial coefficient with natural numbers:

\[
\binom{\beta}{i} = \frac{\beta!}{i!(\beta-i)!} = \frac{\beta(\beta-1)(\beta-2)\cdots}{i!(\beta-i)(\beta-i-1)\cdots} = \frac{\beta \cdots (\beta-i+1)}{i!}
\]

As usual, \(\binom{\beta}{0} = 1\). Now we apply this expansion to \((f_0 * g_A \cdot \sum_{k \neq 0} \theta_k \varphi_k)^{(\beta)}\). Recall the definition:

\([x]\) is the integer part of a real number \(x\), and for \(x\) positive (as in our case) \([x] := [x] + 1\).

\[
\| \left( f_0 * g_A \cdot \sum_{k \neq 0} \theta_k \varphi_k \right)^{(\beta)} \|_2
\]

\[
= \sum_{i=0}^{\infty} \binom{\beta}{i} \left( f_0 * g_A \right)^{(i)} \left( \sum_{k \neq 0} \theta_k \varphi_k \right)^{(\beta-i)} \|_2
\]

\[
\leq \sum_{i=0}^{[\beta]} \binom{\beta}{i} \left( f_0 * g_A \right)^{(i)} \left( \sum_{k \neq 0} \theta_k \varphi_k \right)^{(\beta-i)} \|_2 + \sum_{i=[\beta]}^{\infty} \binom{\beta}{i} \left( f_0 * g_A \right)^{(i)} \left( \sum_{k \neq 0} \theta_k \varphi_k \right)^{(\beta-i)} \|_2
\]

\[
\leq \sum_{i=0}^{[\beta]} \binom{\beta}{i} \max |f_0 * g_A|^{|i|} \left( \sum_{k \neq 0} \theta_k \varphi_k \right)^{(\beta-i)} \|_2 + \sum_{i=[\beta]}^{\infty} \binom{\beta}{i} \left( f_0 * g_A \right)^{(i)} \left( \sum_{k \neq 0} \theta_k \varphi_k \right)^{(\beta-i)} \|_2
\]

\[
\leq \sum_{i=0}^{[\beta]} \binom{\beta}{i} \frac{\| f_0 \|^{|i|}}{2A-1} \left( \sum_{k \neq 0} \theta_k \varphi_k \right)^{(\beta-i)} \|_2 + \sum_{i=[\beta]}^{\infty} \binom{\beta}{i} \left( f_0 * g_A \right)^{(i)} \left( \sum_{k \neq 0} \theta_k \varphi_k \right)^{(\beta-i)} \|_2
\]

where \(\| f_0 \|^{|i|}\) is of course equal to 1 for \(i = 0\) and finite for \(i = 1, \ldots, [\beta]\). When \(\beta \in \mathbb{N}\), then

For \(\beta \geq 1\), clearly \(\| f_0^{(\beta-1)} \|_2 < \infty\) because \(f_0\) lies in \(S\). For \(1/2 < \beta < 1\) we can calculate \(\| f_0^{(\beta-1)} \|_2 = \frac{1}{2\pi} \int |\omega^{\beta-1} \widehat{f}_0(\omega)|^2 d\omega \leq \| f_0 \|^2 + \frac{1}{2\pi} (2\beta - 1)^{-1}\), which is also less than infinity.
\((\beta) = 0\) for all \(i \geq \lfloor \beta \rfloor\), so there is no residual. In the next step we employ:

\[
\left\| \left( \sum_{k \neq 0} \theta_k \varphi_k \right)^{(\gamma)} \right\|_2 = \sum_{k \neq 0} \theta_k^2 \left( \frac{k \pi}{A} \right)^{2\gamma}
\]

(23)

for all \(\gamma\), proven in (28). Furthermore, for \(\Theta_A(L)\), \(\sum |\theta_k| \leq A^{-2\beta+1}\) and \(\sum \theta_k^2 \left( \frac{k \pi}{A} \right)^{2\beta} \leq 4A^2L\) had been determined in (7). Therefrom we can show in (29) that

\[
\sum_{k \neq 0} \theta_k^2 \left( \frac{k \pi}{A} \right)^{2\beta-l} \leq (1 + 4L)A^{2-l} \quad \text{for } 0 < l < 2\beta
\]

(24)

Hence continuing at inequality number (22):

\[
\left\| \left( f_0 * g_A \cdot \sum_{k \neq 0} \theta_k \varphi_k \right)^{(\beta)} \right\|_2 = \sum_{i=0}^{\lfloor \beta \rfloor} \left( \begin{array}{c} \beta \\ i \end{array} \right) \| f_0^{(i)} \|_1 \left( \sum_{k \neq 0} \theta_k^2 \left( \frac{k \pi}{A} \right)^{2(\beta-i)} \right) + \sum_{i=1}^{\lfloor \beta \rfloor} \left( \begin{array}{c} \beta \\ i \end{array} \right) \left( f_0 * g_A \right)^{(i)} \left( \sum_{k \neq 0} \theta_k \varphi_k \right)^{(\beta-i)} \right\|_2
\]

\[
\leq \frac{1}{2A-1} \sqrt{4LA^2} + \sum_{i=1}^{\lfloor \beta \rfloor} \left( \begin{array}{c} \beta \\ i \end{array} \right) \left( \frac{f_0^{(i)}}{2A-1} \right) \left( \sum_{k \neq 0} \theta_k \varphi_k \right)^{(\beta-i)} \right\|_2
\]

(25)

For the residual we apply Lemma 3 to our functions. It states that for functions with support in \([-A, A]\):

\[
\left\| \left( \sum_{i=\lfloor \beta \rfloor} \left( \begin{array}{c} \beta \\ i \end{array} \right) f^{(i)} \cdot g^{(\beta-i)} \right) \right\|_2 = o(A^2) \| f^{(\lfloor \beta \rfloor)} \|_2 \| g \|_2
\]

Setting \(f := f_0 * g_A\) and \(g := \sum \theta_k \varphi_k\), we proceed at inequality number (25):

\[
\left\| \left( f_0 * g_A \cdot \sum_{k \neq 0} \theta_k \varphi_k \right)^{(\beta)} \right\|_2 \leq \frac{1}{2A-1} \sqrt{4LA^2} + \sum_{i=1}^{\lfloor \beta \rfloor} \left( \begin{array}{c} \beta \\ i \end{array} \right) \left( \frac{f_0^{(i)}}{2A-1} \right) \sqrt{(1 + 4L)A^{2-i}}
\]

\[
+ o(A) \| \left( f_0 * g_A \right)^{(\lfloor \beta \rfloor)} \|_1 \left\| \sum_{k \neq 0} \theta_k \varphi_k \right\|_2
\]

\[
= \frac{1}{2A-1} \sqrt{4LA^2} + \sum_{i=1}^{\lfloor \beta \rfloor} \left( \begin{array}{c} \beta \\ i \end{array} \right) \left( \frac{f_0^{(i)}}{2A-1} \right) \sqrt{(1 + 4L)A^{2-i}}
\]

\[
+ o(A) \| \left( f_0 * g_A \right)^{(\lfloor \beta \rfloor)} \|_1 \sqrt{\sum_{k \neq 0} \theta_k^2}
\]

(26)

After having derived the claim of Theorem 2, we will show in (30) that

\[
\left\| (f_0 * g_A)^{(\lfloor \beta \rfloor)} \right\|_1 \leq \frac{\left\| f_0^{(\lfloor \beta \rfloor)} \right\|_1}{A - 1/2}, \quad \text{where} \quad \left\| f_0^{(\lfloor \beta \rfloor)} \right\|_1 < \infty
\]

(27)
Furthermore \( \sum \theta_k^2 \leq \sum |\theta_k| \leq A^{-2\beta+1} \), but \(-2\beta + 1 < 0\), such that (26) can be continued as

\[
\left\| (f_0 * g_A \cdot \sum_{k \neq 0} \theta_k \varphi_k)^{(\beta)} \right\|_2 < \frac{1}{2A-1} \sqrt{4LA^2} + \sum_{i=1}^{\lfloor \frac{\beta}{2} \rfloor} \left\| f_0^{(i)} \right\|_1 \frac{1}{2A-1} \sqrt{(1 + 4L)A^{2-i}}
\]

\[
+ o(A) \frac{1}{\sqrt{A}} \sqrt{\frac{\beta(\beta+1)}{2}} \sqrt{A^{-2\beta+1}}
\]

\[
= \frac{1}{2A-1} \sqrt{4LA^2} + \sum_{i=1}^{\lfloor \frac{\beta}{2} \rfloor} \left\| f_0^{(i)} \right\|_1 \frac{1}{2A-1} \sqrt{(1 + 4L)A^{2-i}}
\]

\[
+ o(A) \frac{1}{\sqrt{A}} \sqrt{\frac{\beta(\beta+1)}{2}} \sqrt{A^{-2\beta+1}}
\]

This result in connection with (20) and (21) completes Theorem 2:

\[
\left\| f_\theta^{(\beta)} \right\|_2 \leq \frac{1}{b(\theta)} \left\| (f_0 * g_A)^{(\beta)} \right\|_2 + \frac{1}{b(\theta)} \left\| (f_0 * g_A \sum_{k \neq 0} \theta_k \varphi_k)^{(\beta)} \right\|_2
\]

\[
= O \left( A^{-1} \right) \left\| f_0^{(\beta-1)} \right\|_2 + \sqrt{L} \left( 1 + o(1) \right)
\]

Still we are left to prove the intermediate assertions (23), (24) and (27).

As an exception to the ordinary case, sine and cosine enjoy an easy to calculate fractional derivative: \( \sin^{(\gamma)}(ax) = a^\gamma \sin \left( ax + \frac{\gamma \pi}{2} \right) \) and the like for cosine (Samko [9], p. 174). Obviously, the orthogonality between our functions \( \varphi_k \) is preserved through derivation.

\[
\int \left( \sum_{k \neq 0} \theta_k \varphi_k^{(\gamma)}(x) \right)^2 \, dx
\]

\[
= \int \sum_{k \neq 0} \theta_k^2 \varphi_k^{(\gamma)}(x)^2 \, dx
\]

\[
= \int_{-A}^{A} \sum_{k > 0} \theta_k^2 \left( \frac{k \pi}{A} \right)^{2\gamma} \cos^2 \left( \frac{k \pi x}{A} + \frac{\gamma \pi}{2} \right) + \sum_{k < 0} \theta_k^2 \left( \frac{k \pi}{A} \right)^{2\gamma} \sin^2 \left( \frac{k \pi x}{A} + \frac{\gamma \pi}{2} \right) \, dx
\]

\[
= \sum_{k > 0} \theta_k^2 \left( \frac{k \pi}{A} \right)^{2\gamma} \frac{1}{A} \int_{-A}^{A} \cos^2 \left( \frac{k \pi x}{A} + \frac{\gamma \pi}{2} \right) \, dx + \sum_{k < 0} \theta_k^2 \left( \frac{k \pi}{A} \right)^{2\gamma} \frac{1}{A} \int_{-A}^{A} \sin^2 \left( \frac{k \pi x}{A} + \frac{\gamma \pi}{2} \right) \, dx
\]

\[
= \sum_{k > 0} \theta_k^2 \left( \frac{k \pi}{A} \right)^{2\gamma} \frac{1}{A} \int_{-A}^{A} \frac{2k \pi x}{A} \, dx + \sum_{k < 0} \theta_k^2 \left( \frac{k \pi}{A} \right)^{2\gamma} \frac{1}{A} \int_{-A}^{A} \frac{2k \pi x}{A} \, dx
\]

\[
= \sum_{k > 0} \theta_k^2 \left( \frac{k \pi}{A} \right)^{2\gamma} \frac{1}{A} A + \sum_{k < 0} \theta_k^2 \left( \frac{k \pi}{A} \right)^{2\gamma} \frac{1}{A} A
\]

\[
= \sum_{k \neq 0} \theta_k^2 \left( \frac{k \pi}{A} \right)^{2\gamma}
\]
Referring to step (24), $0 < l < 2\beta$:

$$
\sum_{k \neq 0} \theta_k^2 \left( \frac{k\pi}{A} \right)^{2\beta-l} = \sum_{0 \neq |k| \leq A^2/\pi} \theta_k^2 \left( \frac{k\pi}{A} \right)^{2\beta-l} + \sum_{|k| > A^2/\pi} \theta_k^2 \left( \frac{k\pi}{A} \right)^{2\beta} \\
\leq A^{2\beta-l} \sum_{0 \neq |k| \leq A^2/\pi} \theta_k^2 + A^{-l} \sum_{|k| > A^2/\pi} \theta_k^2 \left( \frac{k\pi}{A} \right)^{2\beta} \\
\leq A^{2\beta-l} \sum_{k \neq 0} |\theta_k| + A^{-l} \sum_{k \neq 0} \theta_k^2 \left( \frac{k\pi}{A} \right)^{2\beta} \\
= A^{1-l} + 4LA^{2-l} \\
\leq (1 + 4L)A^{2-l} \quad (29)
$$

Proof of (27):

$$
\| (f_0 \ast g)(\lfloor |\beta| \rfloor) \|_1 = \int |\omega|^{|\beta|} \hat{f}_0(\omega) \hat{g}_1(\omega) |d\omega \\
= \int |\omega|^{|\beta|} \hat{f}_0(\omega) \frac{2\sin(A - 1/2)\omega}{(2A - 1)\omega} |d\omega \\
= \frac{1}{A - 1/2} \int |\omega|^{|\beta|} \hat{f}_0(\omega) \sin(A - 1/2)\omega |d\omega \\
\leq \frac{\| f_0(\lfloor |\beta| \rfloor) \|_1}{A - 1/2} \quad (30)
$$

$\| f_0(\lfloor |\beta| \rfloor) \|_1$ exists, because we chose $f_0 \in S$. This concludes the proof of Theorem 2. \hfill \Box

**Lemma 3** For functions $f$ and $g$, which are both $L_2$-integrable, sufficiently regular and have support in $[-A, A]$, it holds that

$$
\left\| \sum_{i=|\beta|}^{\infty} \binom{\beta}{i} f^{(i)} \cdot g^{(\beta-i)} \right\|_2^2 = o(A^2) \left\| f(\lfloor |\beta| \rfloor) \right\|_1^2 \cdot \| g \|_2^2
$$

**Proof** This proof takes a detour via Fourier coefficients. Begin with the following discussion: The power function is an analytical function. We may thus for instance expand $(\frac{\kappa \pi}{A})^\beta$ into an infinite Taylor series at point $(\kappa - \lambda)\pi / A$.

$$
(\frac{\kappa \pi}{A})^\beta = \sum_{i=0}^{\infty} \binom{\beta}{i} \left( \frac{\lambda \pi}{A} \right)^i \left( \frac{(\kappa - \lambda)\pi}{A} \right)^{\beta-i}
$$

We cut the Taylor expansion of $(\frac{\kappa \pi}{A})^\beta$ after $|\beta|$ and bound the residual.

$$
\left| \sum_{i=|\beta|}^{\infty} \binom{\beta}{i} \left( \frac{\lambda \pi}{A} \right)^i \left( \frac{(\kappa - \lambda)\pi}{A} \right)^{\beta-i} \right| \\
= \sum_{i=|\beta|}^{\infty} \binom{\beta}{i} \left( \frac{\lambda \pi}{A} \right)^{|\beta|+i} \left( \frac{(\kappa - \lambda)\pi}{A} \right)^{\beta-|\beta|-i}
$$
The bound of the Taylor series: $|\beta\rangle$. Now we expand the tail of our Leibnitz formula into a Fourier series and plug in the bound: 

$$
\leq \left(\frac{\beta}{[\beta]}\right) |\lambda\pi\rangle \sum_{i=0}^{\infty} \frac{(|\beta|\pi)\cdots(\beta-\beta-i+1)}{i!} \left(\frac{\lambda\pi}{A}\right)^{\beta-\beta-i} \cdot |1\rangle \cdot |\lambda\pi\rangle \cdot \frac{\lambda\pi}{A} \cdot \frac{\lambda\pi}{A} 
$$

The product $(\beta - [\beta]) \cdots (\beta - [\beta] - i + 1)$ consists of $i$ factors, which are all negative. We can write $((\beta - [\beta]) \cdots (\beta - [\beta] - i + 1)) = (-1)^i(\beta - [\beta]) \cdots (\beta - [\beta] - i + 1)$, such that 

$$
|\sum_{i=0}^{\infty} \frac{\beta \cdots (\beta - [\beta] - i + 1)}{([\beta] + i)!} \left(\frac{\lambda\pi}{A}\right)^{\beta+i} \cdot \left(\frac{(\beta - [\beta])\pi}{A}\right)^{\beta-\beta-i} |
$$

$$
= \left(\frac{\beta}{[\beta]}\right) \left|\lambda\pi\right| \sum_{i=0}^{\infty} \frac{(-1)^i(\beta - [\beta]) \cdots (\beta - [\beta] - i + 1)}{i!} \left|\lambda\pi\right|^i \left|\frac{\lambda\pi}{A}\right| \left|\frac{\lambda\pi}{A}\right| \left|\frac{\lambda\pi}{A}\right| 
$$

Since we know that $-1 < \beta - [\beta] < 0$, we can approximate $\left(\frac{(\lambda - \lambda - [\lambda])\pi}{A}\right)^{\beta-\beta} = O(\lambda^{\beta-\beta}) = o(A)$. Now we expand the tail of our Leibnitz formula into a Fourier series and plug in the bound of the Taylor series:

$$
\left\|\sum_{i=0}^{\infty} \left(\frac{\beta}{i}\right) f(i) \cdot g^{(\beta-i)}\right\|_2^2
$$

$$
= \frac{1}{2A} \sum_{\kappa \in \mathbb{Z}} \left(\sum_{i=0}^{\infty} \left(\frac{\beta}{i}\right) f(i) \cdot g^{(\beta-i)} \left(\frac{\lambda\pi}{A}\right)^2 \right)
$$

$$
= \frac{1}{2A} \sum_{\kappa \in \mathbb{Z}} \left(\sum_{i=0}^{\infty} \left(\frac{\beta}{i}\right) \frac{1}{2A} \sum_{\lambda \in \mathbb{Z}} f(i) \left(\frac{\lambda\pi}{A}\right) \cdot g^{(\beta-i)} \left(\frac{\lambda\pi}{A}\right)^2 \right)
$$

$$
= \frac{1}{2A} \sum_{\kappa \in \mathbb{Z}} \left(\sum_{i=0}^{\infty} \left(\frac{\beta}{i}\right) \frac{1}{2A} \sum_{\lambda \in \mathbb{Z}} f(i) \left(\frac{\lambda\pi}{A}\right) \cdot g^{(\beta-i)} \left(\frac{\lambda\pi}{A}\right)^2 \right)
$$

$$
\leq \frac{1}{2A} \sum_{\kappa \in \mathbb{Z}} \left(\frac{1}{2A} \sum_{\lambda \in \mathbb{Z}} o(A) \left(\frac{\beta}{[\beta]}\right) \left|\lambda\pi\right| \left|\frac{\beta}{[\beta]}\right| \cdot g^{(\beta-i)} \left(\frac{\lambda\pi}{A}\right)^2 \right)
$$

$$
= o(A^2) \frac{1}{2A} \sum_{\kappa \in \mathbb{Z}} \sum_{\lambda \in \mathbb{Z}} \left(\frac{\beta}{[\beta]}\right) \left|\lambda\pi\right| \left|\frac{\beta}{[\beta]}\right| \cdot g^{(\beta-i)} \left(\frac{\lambda\pi}{A}\right)^2 \right)
$$
\begin{align*}
\times \frac{1}{2A} \sum_{\mu \in \mathbb{Z}} \left( \beta \right) \left| \frac{\mu \pi}{A} \right| |f(\frac{\mu \pi}{A})| \cdot \hat{g}(\frac{(\kappa - \mu)\pi}{A}) \\
= o(A^2) \left( \frac{\beta}{|\beta|} \right)^2 \left( \frac{1}{2A} \sum_{\lambda \in \mathbb{Z}} |\frac{\lambda \pi}{A}| \right) \left| \hat{f}(\frac{\lambda \pi}{A}) \right| \left( \frac{1}{2A} \sum_{\mu \in \mathbb{Z}} |\frac{\mu \pi}{A}| \right) \left| \hat{f}(\frac{\mu \pi}{A}) \right| \\
\times \frac{1}{2A} \sum_{\kappa \in \mathbb{Z}} \left| \hat{g}(\frac{(\kappa - \lambda)\pi}{A}) \right| \cdot \left| \hat{g}(\frac{(\kappa - \mu)\pi}{A}) \right| \\
\leq o(A^2) \left( \frac{\beta}{|\beta|} \right)^2 \left( \frac{1}{2A} \sum_{\lambda \in \mathbb{Z}} |\frac{\lambda \pi}{A}| \right) \left| \hat{f}(\frac{\lambda \pi}{A}) \right| \left( \frac{1}{2A} \sum_{\mu \in \mathbb{Z}} |\frac{\mu \pi}{A}| \right) \left| \hat{f}(\frac{\mu \pi}{A}) \right| \\
\times \sqrt{\frac{1}{2A} \sum_{\kappa \in \mathbb{Z}} \left| \hat{g}(\frac{(\kappa - \lambda)\pi}{A}) \right|^2} \sqrt{\frac{1}{2A} \sum_{\kappa \in \mathbb{Z}} \left| \hat{g}(\frac{(\kappa - \mu)\pi}{A}) \right|^2} \\
= o(A^2) \left( \frac{\beta}{|\beta|} \right)^2 \left( \frac{1}{2A} \sum_{\lambda \in \mathbb{Z}} |\frac{\lambda \pi}{A}| \right) \left| \hat{f}(\frac{\lambda \pi}{A}) \right|^2 \cdot \|g\|_2^2
\end{align*}

For growing $A$, the Fourier expansion approaches the Fourier transform, and hence

\begin{equation}
\left\| \sum_{i=\lfloor \beta \rfloor}^{\infty} \left( \frac{\beta}{i} \right) f(i) : g(\beta - i) \right\|_2^2
\end{equation}

\begin{align*}
= o(A^2) \left( \frac{\beta}{|\beta|} \right)^2 \left( \frac{1}{2\pi} \int |\omega^{|\beta|} \hat{f}(\omega)| d\omega \left( 1 + o(1) \right) \right)^2 \cdot \|g\|_2^2 \\
= o(A^2) \left\| \hat{f}(|\beta|) \right\|_1^2 \cdot \|g\|_2^2
\end{align*}

which is the statement of Lemma 3. \hfill \square

**Proof of Lemma 2** We start with

\begin{align*}
I_{f_\theta}(\theta, \kappa) \\
= \int_{-\theta}^{\theta} \frac{(\partial f_\theta(x)/\partial \theta)^2}{f_\theta(x)} dx \\
= \frac{1}{b^2(\theta)} \int_{-\theta}^{\theta} \frac{1}{f_\theta(x)} \left[ -f_\theta(x) \int_{-\theta}^{\theta} f_0 * g_A(y) \varphi_\kappa(y) dy + f_0 * g_A(x) \varphi_\kappa(x) \right]^2 dx \\
= \frac{1}{b^2(\theta)} \int_{-\theta}^{\theta} \left[ f_\theta(x) \left( \int_{-\theta}^{\theta} f_0 * g_A(y) \varphi_\kappa(y) dy \right)^2 - 2 \int_{-\theta}^{\theta} f_0 * g_A(y) \varphi_\kappa(y) dy \ f_0 * g_A(x) \varphi_\kappa(x) \right. \\
+ \left. \frac{1}{f_\theta(x)} \left( f_0 * g_A(x) \varphi_\kappa(x) \right)^2 \right] dx \\
= -\frac{1}{b^2(\theta)} \left[ \int_{-\theta}^{\theta} f_0 * g_A(y) \varphi_\kappa(y) dy \right]^2 + \frac{1}{b^2(\theta)} \int_{-\theta}^{\theta} \frac{\left( f_0 * g_A(x) \right)^2}{f_\theta(x)} \frac{\varphi_\kappa^2(x)}{1 + \sum_{\lambda \neq 0} \theta_\lambda \varphi_\lambda(x)} dx \\
= -\frac{1}{b^2(\theta)} \left[ \int_{-\theta}^{\theta} f_0 * g_A(y) \varphi_\kappa(y) dy \right]^2 + \frac{1}{b(\theta)} \int_{-\theta}^{\theta} \frac{f_0 * g_A(x) \varphi_\kappa^2(x)}{1 + \sum_{\lambda \neq 0} \theta_\lambda \varphi_\lambda(x)} dx
\end{align*}
Acknowledgement: I would like to thank Prof. M. Neumann for initiating and supporting the present work.
