INTRAMOLECULAR CYCLIZATION DURING BROMINATION OF THE QUINOLINE ALKALOID HAPLOPHYLLIDINE

A. U. Ubaidullaev,1* V. I. Vinogradova,1 Sh. N. Zhurakulov,1,2 N. I. Mukarramov,1 Kh. M. Bobakulov,1,3 K. A. Turgunov,1 and B. Tashkhodzhaev1

Bromination of the furanoquinoline alkaloid haplophyllidine by molecular bromine and N-bromosuccinimide was accompanied by intramolecular cyclization to form mixtures of new compounds containing additional penta-, hexa-, and spirocyclic rings incorporating the prenyl group of haplophyllidine. The structures and absolute configurations of the chiral centers of all four bromo-derivatives were elucidated using a combination of NMR spectroscopic methods and X-ray crystal structure analyses.

Keywords: haplophyllidine, bromination, molecular bromine, N-bromosuccinimide, cyclization.

Quinoline is well known as the skeletal platform of several extremely interesting natural and synthetic biologically active compounds. Fluoroquinolones such as moxifloxacin [1] and ciprofloxacin [2] are currently widely used in medicine as antimicrobials; mefloquine (4-methanolquinoline derivative) [3] and chloroquine (4-aminoquinoline derivative) [4], as antimalariais. The last is undergoing clinical trials for treatment of COVID-19 [5, 6]. Pitavastatin, which contains a 4-fluorophenylquinoline moiety, is one of the newest statins and is used to reduce blood lipid levels and the risk of cardiovascular diseases [7].

The diverse high activity of quinoline compounds has prompted efforts to modify quinoline alkaloids. Halogenation, which can produce promising biologically active compounds and reactive intermediates, is one possible transformation pathway. Therefore, it seemed interesting to study the bromination products of haplophyllidine (1), the structure of which includes a prenyl group, by bromine and N-bromosuccinimide (NBS), which are widely used for bromination of alkenes in side chains of heteroaromatic compounds and for the synthesis of five-membered heterocyclic compounds [8]. Haplophyllidine, the structure and relative configuration of which were previously established [9], was isolated from seeds of Haplophyllum perforatum growing in Samarkand Region of Uzbekistan [10].

Herein, results from the bromination of 1 by molecular bromine in CHCl3 (method A) and by NBS in CHCl3 (method B) and DMF (method C) are reported. The addition of Br was facilitated by the two methyls on the prenyl double bond. The bromination turned out to be exceedingly interesting and promising for synthesizing a series of cyclic products. Bromination in all three reaction methods formed a mixture of products that could not always be successfully separated by column chromatography. Therefore, it seemed logical to use HPLC to estimate the product yields. As a result, it was found that four products (2–5) formed in the reactions according to methods A and B and three products (2, 4, and 5), method C (Table 1, Scheme 1). The dibromo-derivative of 1 was not observed to form in any of the reactions.

Table 1 shows that bromination in CHCl3, regardless of the reagent, gave a mixture of compounds, the major constituents of which were 3 (41%, A) and bromo-derivatives 3 and 5 (~32% each, B) while 3 was not detected under the conditions of reaction C.

The structures of isolated 3–5 were proved by spectral methods and X-ray crystal structure analyses (XSAs). The chemical structure of 2, which was isolated as an oil, was elucidated by analyzing 1H and 13C NMR spectra and HSQC, HMBC, DQF-COSY, and NOESY experiments. Resonances of protons and C atoms in 1H and 13C NMR spectra were assigned by using HSQC and COSY experiments. The strong-field part of the 1H NMR spectrum of 2 showed two singlets for methyls at $\delta$ 1.33 (H-12) and 1.45 (H-13) and resonances for three methylenes at $\delta$ 1.99 (dddd, J = 13.4, 7.5, 6.7, 5.0 Hz, H-6a), 2.13 (ddddd, J = 13.4, 8.7, 5.0 Hz, H-6b), 2.65 (dddd, J = 16.6, 6.7, 5.0 Hz, H-5a), and 2.80 (m, H-9). The middle of the proton spectrum displayed two doublets of doublets at $\delta$ 4.18 (dd, J = 7.4, 3.3 Hz, H-7) and 4.44 (dd, J = 7.3, 6.5 Hz, H-10), which were characteristic of protons on a C atom bound to oxygen, and 3H singlets at 3.14 and 4.27 ppm for C-8 and C-4 methoxyls, respectively. The aromatic part of the spectrum had only two 1H doublets with $\text{SSCC } J = 2.6$ Hz at $\delta$H 7.57 ppm (H-2) and 6.95 (H-3) that corresponded to protons of the furan ring [11].

An analysis of 13C NMR and HSQC spectra of 2 showed 18 resonances for C atoms as seven quaternary, including five on a heteroatom; four methine; three methylene; and four methyl C atoms. The weak-field region of the 13C NMR spectrum had resonances for three quaternary C atoms at $\delta$ 162.86 (C-1a), 158.01 (C-4), and 150.96 (C-8a) and for a protonated C atom at $\delta$ 142.90 (C-2), which was determined from an HSQC experiment of the furanopyridine motif. The aromatic range of C atoms revealed resonances of a second methine C atom at $\delta$ 104.82 (C-3) and two quaternary C atoms at $\delta$ 105.36 (C-3a) and 118.16 (C-4a).

Three resonances at stronger field that were characteristic of C atoms bound to oxygen were observed at $\delta$ 76.99 (C-8), 74.92 (C-11), and 71.57 (C-7). Next, the spectrum showed resonances of two methoxyls at $\delta$ 58.65 (C-14) and 51.32 (C-15), two methyls at 27.06 (C-12) and 25.63 (C-13), and the other aliphatic C atoms. The positions of the two methoxyls and two methyls were established from an HMBC experiment. The presence in the HMBC spectrum of cross-peaks H-14/C-4, H-15/C-8, and H-12(H-13)/C-10, C-11 indicated that the methoxy groups were situated on C-4 and C-8, respectively; the two methyls, on C-11. The spectrum also had cross-peaks between H-2/H-3, H-5/H-6, H-9/H-10, and C-12, C-13. Also, correlations were found in the DQF-COSY spectrum between H-2/H-3, H-5/H-6, H-9/H-10, and H-9/H-10. These data showed that an additional six-membered ring was present in 2 as compared to the starting alkaloid 1.

### TABLE 1. Yield of Bromination Products (HPLC)

| Bromination method     | Bromination product, % |
|------------------------|------------------------|
| A (Br$_2$, CHCl$_3$)   | 20.2                   |
| B (NBS, CHCl$_3$)      | 15.6                   |
| C (NBS, DMF)           | 24                     |

| Bromination product   | 2  | 3  | 4  | 5  |
|-----------------------|----|----|----|----|
| À (Br$_2$, CHCl$_3$)  | 20.2| 41 | 9  | 12 |
| (NBS, CHCl$_3$)       | 15.6| 32 | 17.2| 32.7|
| (NBS, DMF)            | 24  | Not detected | 30 | 39 |

Scheme 1. Bromination of haplophyllidine (1) by molecular bromine and N-bromosuccinimide (NBS).

The structures of isolated 3–5 were proved by spectral methods and X-ray crystal structure analyses (XSAs). The chemical structure of 2, which was isolated as an oil, was elucidated by analyzing 1H and 13C NMR spectra and HSQC, HMBC, DQF-COSY, and NOESY experiments. Resonances of protons and C atoms in 1H and 13C NMR spectra were assigned by using HSQC and COSY experiments. The strong-field part of the 1H NMR spectrum of 2 showed two singlets for methyls at $\delta$ 1.33 (H-12) and 1.45 (H-13) and resonances for three methylenes at $\delta$ 1.99 (dddd, J = 13.4, 7.5, 6.7, 5.0 Hz, H-6a), 2.13 (ddddd, J = 13.4, 8.7, 5.0 Hz, H-6b), 2.65 (dddd, J = 16.6, 6.7, 5.0 Hz, H-5a), and 2.80 (m, H-9). The middle of the proton spectrum displayed two doublets of doublets at $\delta$ 4.18 (dd, J = 7.4, 3.3 Hz, H-7) and 4.44 (dd, J = 7.3, 6.5 Hz, H-10), which were characteristic of protons on a C atom bound to oxygen, and 3H singlets at 3.14 and 4.27 ppm for C-8 and C-4 methoxyls, respectively. The aromatic part of the spectrum had only two 1H doublets with $\text{SSCC } J = 2.6$ Hz at $\delta$H 7.57 ppm (H-2) and 6.95 (H-3) that corresponded to protons of the furan ring [11].

An analysis of 13C NMR and HSQC spectra of 2 showed 18 resonances for C atoms as seven quaternary, including five on a heteroatom; four methine; three methylene; and four methyl C atoms. The weak-field region of the 13C NMR spectrum had resonances for three quaternary C atoms at $\delta$ 162.86 (C-1a), 158.01 (C-4), and 150.96 (C-8a) and for a protonated C atom at $\delta$ 142.90 (C-2), which was determined from an HSQC experiment of the furanopyridine motif. The aromatic range of C atoms revealed resonances of a second methine C atom at $\delta$ 104.82 (C-3) and two quaternary C atoms at $\delta$ 105.36 (C-3a) and 118.16 (C-4a).

Three resonances at stronger field that were characteristic of C atoms bound to oxygen were observed at $\delta$ 76.99 (C-8), 74.92 (C-11), and 71.57 (C-7). Next, the spectrum showed resonances of two methoxyls at $\delta$ 58.65 (C-14) and 51.32 (C-15), two methyls at 27.06 (C-12) and 25.63 (C-13), and the other aliphatic C atoms. The positions of the two methoxyls and two methyls were established from an HMBC experiment. The presence in the HMBC spectrum of cross-peaks H-14/C-4, H-15/C-8, and H-12(H-13)/C-10, C-11 indicated that the methoxy groups were situated on C-4 and C-8, respectively; the two methyls, on C-11. The spectrum also had cross-peaks between H-2/H-3, H-5/H-6, H-9/H-10, and C-12, C-13. Also, correlations were found in the DQF-COSY spectrum between H-2/H-3, H-5/H-6, H-9/H-10, and H-9/H-10. These data showed that an additional six-membered ring was present in 2 as compared to the starting alkaloid 1.
TABLE 2. Chemical Shifts in $^{1}$H and $^{13}$C NMR Spectra of 2 and 4 (ppm, J/Hz) and HMBC Experimental Data

| C atom | $\delta_{C}$ (ppm) | $\delta_{H}$ (ppm) | HMBC (H→C) | $\delta_{C}$ (ppm) | $\delta_{H}$ (ppm) |
|--------|------------------|------------------|-------------|------------------|------------------|
| 1a     | 162.86           |                  |             |                  | 162.18           |

| 13     | 25.63            | 1.45 (s)         | 3a, 4       | 28.70           |
| 14     | 58.65            | 4.27 (s)         | 8           | 58.60           |
|        |                  |                  |             | 4.28 (s)        |
| 15     | 51.32            | 3.14 (s)         |             | 50.90           |
|        |                  |                  |             | 3.24 (s)        |

The relative configuration of 2 was established based on the NOESY spectrum. NOE correlations between protons H-7/H-10, H-13, H-15 were indicative of coplanarity and the $\beta$-orientation of these protons. Table 2 presents detailed $^{1}$H and $^{13}$C NMR spectral data and HMBC correlations for 2. Thus, the structure (7$R$,8$R$,10$S$)-10-bromo-4,8-dimethoxy-11,11-dimethyl-5,6,7,8,10,11-hexahydro-9$H$-furo[2,3-$b$]pyrano[2,3-$h$]quinoline was found for 2 based on the above data.

Resonances in $^{1}$H and $^{13}$C NMR spectra of 4 were assigned based on HSQC and HMBC experiments (Table 2). Products 2 and 4 were found to be epimers at C-10. A comparative analysis of the results revealed several differences in the PMR spectra of these compounds. Protons H-9 in cyclic product 4 resonated at $\delta_{H}$ 2.19 (dd, J = 12.0, 12.9 Hz) and 3.50 (dd, J = 12.0, 4.2 Hz) while the resonance of $\alpha$-proton H-10 was shifted by 0.57 ppm to strong field. Also, the C-12 resonance of 4 was shifted (δ 18.23) as compared to that of 2 (δ 27.06). An XSA established the structure of 4 as (7$R$,8$R$,10$R$)-10-bromo-4,8-dimethoxy-11,11-dimethyl-5,6,7,8,10,11-hexahydro-9$H$-furo[2,3-$b$]pyrano[2,3-$h$]quinoline.

The structure of 3 was established as a bromo-derivative of an oxaspiroquinoline using 2D NMR spectroscopy and an XSA. The NMR spectroscopic data showed that 3 also contained a new ring. Thus, resonances of a methyl (H3CO-8 at δ 3.18 ppm) and an olefin [H-10 (δ 5.35 ppm) and C-10 (δ 54.64 ppm) and C-11 (δ 74.92 ppm)] disappeared from NMR spectra of starting 1. The disappearance of the C-10-C-11 double bond in 1 was compensated by the appearance in 3 of a new five-membered ring based on the prenyl group of 1. The lack of a methyl resonance at 3.18 ppm indicated that the new ring closed through the oxygen on C-8. Also, the multiplicities of the 7-OH and H-7 resonances were observed to change and the H-9b resonance shifted to strong field (δ 3.26→2.77 ppm). Proton H-10 in 3 resonated at δ 5.04 (1H, dd, J = 11.4, 7.1 Hz). The resonances of the other protons of oxaspiroquinoline 3 and starting 1, including two singlets from magnetically nonequivalent geminal CH$_3$ groups, appeared in analogous regions. The $^{13}$C NMR spectrum of 3 had resonances at δ 85.1 (spiro C), 84.0, and 53.9 ppm that were attributed to C-8, C-11, and C-10, which resonated in starting 1 at δ 79.2, 134.1, and 119.8 ppm, respectively. It is noteworthy that cycloadition at an exocyclic double bond is one of the methods used to synthesize spirocyclic compounds [12] although the prenyl double bond and the methoxyl O atom of haplophyllidine were involved in the formation of spirocyclic 3.

The $^{1}$H NMR spectrum of 5 was missing the 7-OH resonance while H-9 resonated at δ 2.15 (dd, J = 10.6, 13.3 Hz) and 2.69 (dd, J = 5.3, 13.3 Hz). Also, the H-10 resonance underwent a strong-field shift by 0.83 ppm (δH 4.52, dd, J = 9.2, 4.9 Hz) as compared to 1. The $^{13}$C NMR spectrum of 5 had substantial changes in the chemical shifts of C-7, C-8, C-10, and C-11, which were observed at δ 86.5 (C-8), 85.5 (C-10), 80.4 (C-7), and 67.5 (C-11). The structure (7$R$,8$R$,10$R$)-10-(2′-bromopropan-2′-yl)-4,8-dimethoxy-5,6,7,8,9,10-hexahydrofuro[2,3-$b$;2,3-$h$]quinoline was proposed for 5 based on the results and was confirmed by an XSA.
The formation of the variously structured intramolecular cyclization products 2–5 through the action of the brominating agents in CHCl₃ provided the basis for a scheme of the reaction mechanism that explained well the experimental results using generally known concepts of the bromination mechanism of ethylene bonds (Scheme 2). The formation of two bromonium cations (A and B) is one reason for the different directions of the reactions. The presence of hydroxyl (7α-OH), methoxyl (8β-OCH₃), and –N= groups in 1 that stabilized carbocations formed at C-10 and C-11 led to several cyclic reaction products.

The outcome of the final cyclization step depended on the degree of localization of negative charge on the oxide atoms and on the regioisomerization of the bromonium cations (A and B). The ionic charge of the bromonium ion and the ability of a methoxyl ion to attack it (bromination method C) decreased if the polarity of the solvent was increased (DMF as compared to CHCl₃).

The structures of the bromination products were difficult to establish based on spectral methods, particularly NMR spectroscopy. Therefore, the structures of the obtained compounds were established using XSA analyses, which proved the structures of 3–5 and the absolute configurations of the chiral centers of the synthesized cyclic derivatives.

Figure 1 shows the molecular structures of 3–5, which agreed with the absolute configurations. The Flack parameters for these compounds were 0.009(13), 0.027(11), and 0.020(7). The presence of the heavy Br atom in the bromination products enabled the absolute configurations to be reliably determined as 7R,8R,10S (3), 7R,8R,10R (4), and 7R,8R,10R (5). The Br atom and C-11 methyl group were disordered in 5 and exchanged places in approximately equal ratios (one of the fixed positions of the molecule is shown in Fig. 1). Therefore, the temperature factors are greater for these atoms and the Csp³–Csp³ bond distances are anomalously elongated in this motif. Otherwise, the bond distances and angles fell within 3σ of the usual values [13].

The core in the molecular structures of tetrahydrofuranoquinoline derivatives 3–5 was almost planar except for ring A. Ring A in 3 adopted a 6α-sofa conformation; the oxaspiro-bonded heterocycle, a half-chair. Ring A in 4 adopted a half-chair conformation with C-6 and C-7 deviating from the plane of the other four. The condensed six-membered oxaspiro heterocycle had a chair conformation. Ring A in 5 had another half-chair shape that was related to the deviation of C-6 and C-7 to the opposite side; the five-membered heterocycle, an envelope conformation.
Anomalously short van-der-Waals intermolecular contacts were not observed in crystals of the molecules. Thus, we showed that bromination of 1 by Br₂ and NBS was associated with addition of Br and intramolecular cyclization involving the prenyl double bond and the O atom of the hydroxyl or methoxyl group to form additional penta-, hexa-, and spirocyclic structures.

**EXPERIMENTAL**

The yield and purity of compounds were determined using a Shimadzu LC-20 HPLC (Japan) and a C18 column (Shimadzu LC-20, Japan). IR spectra were recorded from KBr pellets on a System 2000 FT-IR spectrometer (PerkinElmer, USA). Mass spectra were measured in a CAMAG TLC-MS with an ACQUITY QDa detector. NMR spectra were recorded in CDCl₃ on JNM-ECZ400R and JNM-ECZ600R spectrometers (JEOL, Japan) at operating frequencies 400 and 600 MHz for ¹H. The internal standard in PMR spectra was TMS (0 ppm); in ¹³C NMR spectra, the solvent chemical shift (CDCl₃, 77.16 ppm vs. TMS). NMR spectra were processed using MestReNova 14.2.0 software (Mestrelab Research S.L., Santiago de Compostela, Spain). The course of reactions and purity of products were monitored by TLC on Sigma-Aldrich Silufol L/W plates (10 × 20 cm) with a 254-nm fluorescent indicator (Germany) using benzene–EtOAc (2:1). Melting points of all synthesized compounds were measured on a Boetius apparatus.

**TABLE 3. Main Crystallographic Parameters and Characteristics of X-ray Crystal Structure Analyses of 3–5**

| Parameter                          | 3             | 4             | 5             |

Fig. 1. Molecular structures of 3–5.

Anomalously short van-der-Waals intermolecular contacts were not observed in crystals of the molecules. Thus, we showed that bromination of 1 by Br₂ and NBS was associated with addition of Br and intramolecular cyclization involving the prenyl double bond and the O atom of the hydroxyl or methoxyl group to form additional penta-, hexa-, and spirocyclic structures.
Haplophyllidine (5,6,7,8-tetrahydro-4,8-dimethoxy-8-(3-methyl-2-butenyl)furo[2,3-b]quinolin-7-ol (1) was isolated from seeds of *H. perforatum* by the literature method [10]. 1H NMR (400 MHz, CDCl₃, δ, ppm, J/Hz): 1.68 (3H, s, H-12), 1.73 (3H, s, H-13), 1.96 (1H, brs, 7-OH), 2.01 (1H, m, H-6a), 2.29 (1H, m, H-6b), 2.65 (1H, dd, J = 15.8, 8.4, H-9a), 2.77 (2H, m, H-5), 3.18 (3H, s, 8-OCH₃), 3.26 (1H, dd, J = 15.8, 5.8, H-9b), 4.19 (1H, m, H-7), 4.27 (3H, s, 4-OCH₃), 5.35 (1H, m, H-10), 6.96 (1H, d, J = 2.6, H-3), 7.56 (1H, d, J = 2.6, H-2). 13C NMR (100 MHz, CDCl₃, δ, ppm): 162.49 (C-1a), 158.49 (C-4), 150.53 (C-8a), 142.64 (C-2), 134.13 (C-11), 119.82 (C-10), 117.23 (C-4a), 105.15 (C-3a), 104.84 (C-3), 79.19 (C-8), 70.03 (C-7), 58.57 (C-14), 50.84 (C-15), 30.32 (C-9), 26.24 (C-13), 24.16 (C-6), 18.78 (C-5), 18.21 (C-12).

**Bromination of 1 by Molecular Br₂.** A solution of 1 (0.5 g, 1.58 mmol) in CHCl₃ (4 mL) was stirred, treated dropwise with a solution of Br₂ (0.3 g, 1.875 mmol) in CHCl₃ (2 mL) over 5 min, and stirred for 4 h at 20–25°C. The course of the reaction was monitored by TLC. When the reaction was finished, the solvent was distilled off. The oily residue containing four compounds (*Rf* 0.70, 0.67, 0.65, 0.50; benzene–EtOAc, 2:1) was purified over a column of silica gel using benzene–CHCl₃ (100:1 → 100:10). Three pure products were obtained.

(7R,8R,10S)-10-Bromo-4,8-dimethoxy-11,11-dimethyl-5,6,7,8,10,11-hexahydro-9H-furo[2,3-b]pyrano[2,3-b]quinoline (2), oily compound, *Rf* 0.65, C₁₈H₂₂BrNO₄. ESI-MS *m/z*: 364.1275 [M – OCH₃]+ for Br⁷⁹, 366.0756 [M – OCH₃]+ for Br⁸¹ (calkd for C₁₇H₁₉BrNO₃, 364.2584, 366.2563). Table 2 lists the 1H and 13C NMR spectral data.

(7R,8R,10S)-10-Bromo-4-methoxy-11,11-dimethyl-6,7,10,11-tetrahydro-9H,5H-spiro(furan-2,8-furo[2,3-b]quinolin-7-ol) (3), colorless crystals, mp 192–194°C (MeOH), *Rf* 0.70. IR (KBr, ν, cm⁻¹): 3598 (OH), 2984, 2924, 2931, 2862, 1609, 1581, 1541, 1459. 1H NMR (400 MHz, CDCl₃, δ, ppm, J/Hz): 1.45 (3H, s, H-12), 1.59 (3H, s, H-13), 1.85 (1H, m, H-6b), 2.05 (1H, d, J = 6.0, 7-OH), 2.24 (1H, m, H-6a), 2.66 (1H, dd, J = 7.1, 2.5, H-9a), 2.77 (3H, m, H-5, 8-OCH₃), 4.06 (1H, brd, J = 8.8, H-7), 4.23 (3H, s, 4-OCH₃), 5.04 (1H, dd, J = 11.4, 7.1, H-10), 6.90 (1H, d, J = 2.6, H-3), 7.51 (1H, d, J = 2.6, H-2). 13C NMR (100 MHz, CDCl₃, δ, ppm): 163.12 (C-1a), 158.28 (C-4), 153.74 (C-8a), 142.55 (C-2), 114.97 (C-4a), 110.00 (C-3a), 104.76 (C-3), 85.08 (C-11), 84.03 (C-8), 72.58 (C-7), 58.57 (C-14), 53.93 (C-10), 42.13 (C-9), 26.81 (C-13), 26.36 (C-6), 25.72 (C-5), 19.26 (C-12).

(7R,8R,10R)-10-Bromo-4,8-dimethoxy-11,11-dimethyl-5,6,7,8,10,11-hexahydro-9H-furo[2,3-b]pyrano[2,3-b]quinoline (4), colorless crystals, mp 192–194°C (MeOH), *Rf* 0.70. IR (KBr, ν, cm⁻¹): 3126, 2984, 2942, 2903, 1607, 1578, 1459. C₁₈H₂₂BrNO₄. ESI-MS *m/z*: 363.9696 [M – OCH₃]+ for Br⁷⁹, 366.0756 [M – OCH₃]+ for Br⁸¹ (calkd for C₁₇H₁₉BrNO₃, 364.2584, 366.2563). Table 2 lists the 1H and 13C NMR spectral data.

**Bromination of 1 by NBS in CHCl₃.** A solution of 1 (0.3 g, 1.875 mmol) in CHCl₃ (2 mL) was stirred, treated with a suspension of NBS (0.2 g, 1.12 mmol) in CHCl₃ (2 mL) over 10 min, and stirred for 5 h at 20–25°C. The course of the reaction was monitored by TLC. When the reaction was finished, the mixture was treated with ice water (5 mL). The resulting precipitate containing three compounds (*Rf* 0.70, 0.67, 0.65, C₁₈H₂₂BrNO₄. ESI-MS *m/z*: 363.9696 [M – OCH₃]+ for Br⁷⁹, 366.0756 [M – OCH₃]+ for Br⁸¹ (calkd for C₁₇H₁₉BrNO₃, 364.2584, 366.2563). Table 2 lists the 1H and 13C NMR spectral data.

**Bromination of 1 by NBS in DMF.** A cold (0°C) solution of 1 (0.5 g, 1.58 mmol) in DMF (5 mL) was stirred, treated with NBS (0.336 g, 1.885 mmol) over 10 min, and stirred for 4 h at 20–25°C. The course of the reaction was monitored by TLC. When the reaction was finished, the mixture was treated with ice water (5 mL). The resulting precipitate containing three compounds (*Rf* 0.70, 0.67, 0.65, 0.50) was separated and purified over a column of silica gel using benzene–EtOAc (100:1 → 100:10). Only 4 was isolated pure. Crystals, mp 192–194°C, *Rf* 0.70 (benzene–EtOAc, 2:1).

**Preparation of Solution of Reference Standard for HPLC.** An accurate weight (1.25 mg) of reference (or test) standard was placed into a 10-mL volumetric flask, treated with EtOH (5 mL), mixed for 10 min in an ultrasound bath, diluted to the mark with the same solvent, stirred, and filtered through a 0.45-μm membrane filter.

| Solvent | Time, min |
|---------|-----------|
| H₂O     | 0.01      |
| 20.00   | 0.00      |
| 40.00   | 0.00      |
| 50.00   | 0.00      |
| 51.00   | 0.00      |
| 55.00   | 0.00      |
| 55.00   | Stop      |

MeCN    30 100 100 100 30 30 30

1106
Chromatography conditions: chromatograph with manual injector, high-pressure pump, UV detector, Supelco C18 column (4.6 × 150 mm, 5 μm), room temperature, UV detection at 220 nm. The mobile phase was a gradient of H₂O and MeCN at flow rate 1.0 mL/min. The injected sample volume was 20 μL; analysis time, 55 min. The column was equilibrated with H₂O to achieve a stable baseline. For this, eluent was passed through the column for 30 min at flow rate 1.0 mL/min.

**XSA.** Single crystals were grown by slow evaporation of solvent at room temperature. They were transparent and prismatic. The unit cell constants of a crystal were determined and refined on an HPC XtaLAB Synergy diffractometer (Rigaku, Japan) using Cu Kα-radiation (T = 293 K, graphite monochromator). A three-dimensional dataset of reflections was obtained on the same diffractometer. Absorption corrections were applied by a semi-empirical method using the SADABS program [14]. Table 3 presents the main crystallographic parameters and characteristics of the XSA and refinement calculations for crystals of 3–5.

The structure was solved by direct methods using the SHELXS-97 program suite [15] and refined using calculations in the SHELXL-97 program [16]. All nonhydrogen atoms were refined by anisotropic full-matrix least-squares methods (over \( F^2 \)). Positions of H atoms were found geometrically and refined with fixed isotropic shift parameters \( U_{iso} = nU_{eq} \), where \( n = 1.5 \) for methyls and 1.2 for others and \( U_{eq} \) is the equivalent isotropic shift parameter of the corresponding C atoms. H atoms of hydroxyls were found in difference electron-density syntheses and refined isotropically.
