Climate Impacts and Adaptation Strategies of the Bangladeshi Coastal Communities

Edris Alam

Department of Geography and Environmental Studies, University of Chittagong, Chittagong-4331, Bangladesh

Abstract: Bangladesh is considered one of the most vulnerable countries to climate variability, fluctuation and extreme climatic events. Bangladeshi coastal communities are continuously adopting self-instinct survival strategies in order to cope with changing climatic conditions. This paper discusses the impact of climate change on livelihoods and documents current and future adaptation strategies of the Bangladeshi coastal communities from documentary sources. Later, it undertook validation processes of these finding by field visits, observations and Focus Group Discussions (FGDs). The findings suggest that climate change effects on local community may include, but not limited to, livelihood, migration and health in Bangladesh. To offset the effects of extreme climatic events, vulnerable communities are often forced to migrate within the country. The findings of the research indicate that those who migrated to another area were able to secure new places to reside but in locations that made them susceptible to other forms of disaster.

Keywords: Climate Change, Effects, Adaptation, Community Resilience, Bangladesh Coast

Introduction

Climate change is one of the greatest threats to human life and security (Burton et al., 2006; IPCC, 2007; Yamin et al., 2005; Alam et al., 2017). Mitigation of the Green House Gases (GHGs) and adaptation to live with the changing environment are considered two anthropogenic ways for tackling climate change (Fussel and Klein, 2006; IPCC, 2014). Climate change adaptation refers to adjustment of the natural or human systems in response to actual or expected climatic stimuli or their effects, which moderate harms or exploits beneficial opportunities (Perry et al., 2007). Building the capacity to adapt to climate change implies that people must protect themselves against inevitable new and exogenous threats to their health and wellbeing (Collins, 2008). The U.N. Intergovernmental Panel on Climate Change notes that “adaptation to climate change takes place through adjustments to reduce vulnerability or enhance resilience in responses to observed or expected changes in climate and associated extreme weather events” (IPCC, 2014). Coastal hazards (i.e., tropical cyclones and coastal erosion) are regarded as the greatest threats to human life and security in many countries. Bangladesh, which has a predominantly agricultural economy, a rapidly increasing population and a slow economic growth rate, is currently ranked as one of the most prone to natural disasters (WB, 2005). Bangladesh has a coastline over 710 km, joining the vast 47,201 km² area of coastal plain with the Bay of Bengal (BBS, 2011). The country has 64 administrative districts (BBS, 2011), 19 of which are considered coastal (Karim and Mimura, 2008). The coastal zone accounts for 32% of the total area of the country (Fig. 1); and 28% of the population lives in this zone. The landward limit of the coastal zone from the shore is between 30 and 195 km.

For this research, resilience means ‘the degree to which individuals able organize themselves on the basis of learning from past disasters and continuous climate change adaptation to provide better future human security and improved risk reduction strategies’. It is known that frequent natural hazards coupled with climate change will present complex development challenges for remote rural communities (CRED, 2011; Twigg and Bhatt, 1998; Ayers, et al., 2014).
Fig. 1: Location of Bangladesh coast and selected study areas for this research

Fig. 2: Devastation to houses and the type of temporary houses after Cyclone Sidr in 2007 (Source: The author)
The WB (2005) estimates that 97% of the total area and 99% of the population of Bangladesh are at risk from multiple hazards such as cyclone, flood, drought, earthquake and tornado. From the early history of human settlement on the Bangladesh coast, many people chose to situate their homes along unstable riverbanks or insecure offshore islands located in the northern end of the Bay of Bengal, where living conditions were affordable and livelihood opportunities plentiful. However, many of these offshore communities (e.g., Sandwip, Kutubdia and Hatiya) have been severely affected by coastal erosion. To offset the impact of disasters, the coastal people are continuously applying adaptation strategies for sustaining livelihoods, human habitations and health resilience.

As a signatory of the United Nations Framework Convention on Climate Change (UNFCCC), Bangladesh developed a National Adaptation Program of Actions (NAPA) in 2005. The NAPA identified potential impacts of climate change, vulnerable sectors and geographic areas; and proposed the most important and immediate adaptation actions (Huq, 2011). Three years later, the Ministry of Environment and Forests published the Bangladesh Climate Change Strategy and Action Plan (BCCSAP), a “living document” that aims at developing long-term practical strategies to mitigate climate change risks (MoEF, 2009). Non-Governmental Organizations (NGOs), too, have been making significant contributions in promoting local residents’ health, sustainable livelihoods and mitigating disasters in Bangladesh, notably in significantly reducing waterborne diseases and promoting alternative livelihoods among the Bangladeshi coastal communities. For example, the Caritas Bangladesh, an NGOs and its local partner, Sushilon, assisted local communities in southwestern Bangladesh in emptying and cleaning ponds, which are their residents’ sole sources of drinking water. The implementation of these programs has markedly decreased the incidence of diarrhea, dysentery and skin diseases, which had been widespread among the local residents (Khan et al., 2011). The hazard-affected communities in Bangladesh are well known to taking their own initiatives (Alam, 2002; Alam and Collins, 2010) to cope with major disruptive events. There is currently a clear absence of grounded research to identify local level climate change and its impacts and only a limited understanding of community level adaptation and coping even though it is known that rural communities do cope with disaster. In light of the introduction, this research aims to identify reported effects of climate change on life and livelihood of the Bangladeshi coastal communities and subsequent community led adaptation strategies to live with changing climate extremes. After documenting climate extreme impacts and adaptation strategies, this paper comments on aspects of community resilience to climate change and provides subsequent discussion and conclusions.

Reported Effects of Climate Extreme on Bangladeshi Coastal Communities

Climate change effects may include, but not limited to, livelihood, migration and health (Table 1). This paper only reports those effects that peer reviewed journal articles have attributed to climate change. It attempted to analyse key literature on climate change impact on livelihood, human habitations and health on Bangladesh coast. The real cause of migration, food insecurity and health problems or other social problems often attributed to climate change is difficult to determine because some other factors may also cause these to happen. For example, people may wish to migrate from their homes to other areas not only due to climate change and its associated problems but also for some other pull factors (i.e., job opportunity, education, health and etc.). However, it is impossible to dismiss climate change as one of the main push factors (Luetz, 2013). Bangladeshi communities are vulnerable to climate extreme and other hazards due to a variety of socio-cultural and economic factors.

Community-Led Adaptation Actions

In order to understand community-led adaptation strategies, the activities of this research can be divided into two phases. In the first phase (December 2015 to February 2016), relevant key literature on climate change adaptation for livelihoods, human habitations and health were collected, collated and analysed. In the second phase (March 2016 to April 2016), two field visits and six FGDs were conducted with local residents in Sandwip and Kutubdia islands (Fig. 1) - the locations where the other authors did not visit. Six FGDs were conducted, which include two in each location, consisting of 10 people in each group (equal number of male and female in each group) at a convenient time and place for the participants. The respondents of the FGDs were randomly selected for interview. The duration of the each FGD was approximately 1 hour. The ages of the participants in the FGDs were over twenty-five. The occupations of the FGDs participants included labourer, local vehicle drivers, farmers, fishermen, housewives and small shopkeepers.
Table 1: Reported effects of climate extreme on Bangladeshi coastal communities

| Sectors of effects       | Description of effects                                                                 | Sources                              |
|--------------------------|----------------------------------------------------------------------------------------|--------------------------------------|
| Livelihood               |                                                                                        |                                      |
| Food security            | Decrease of rice production                                                           | Ali (2006)                           |
| Fishing                  | Decrease in fish catch in the Bay of Bengal and Bangladesh coast Islam ADDIN            | Islam (2009)                         |
| Food diversity           | Decrease in crop varieties due to intrusion of saline water and monoculture           | Khan et al. (2011)                   |
| Migration                |                                                                                        |                                      |
| Forced migration from the coast to the inland Bangladesh | The inhabitants in the remote island areas of the Bay of Bengal, when lost their habitations due to coastal erosion and storm surge inundation, migrated to adjacent urban areas. They generally formed two types of settlements. These are: (i) slum dwelling within major city areas and (ii) settlements adjacent to the hills. | Black et al. (2011)                  |
| Forced migration from the coast to adjacent Indian regions | Sea level rise and natural hazard induced displaced people from the Bangladesh coast have taken shelter in adjacent India illegally. | Bose (2013)                          |
| Health                   |                                                                                        |                                      |
| Deaths and injuries      | Deaths resulting from cardio-respiratory diseases associated with high and low temperatures | Rashid et al. (2013)                 |
| Malnutrition             | Higher malnutrition rate among coastal residents due to the reduction of food diversity | Khan et al. (2011)                   |
| Safe drinking water      | Rise of tide levels and frequent coastal flooding Increase salinity in groundwater. Drinking of saline contaminated water increases eclampsia and hyper tension among women in coastal areas | Khan et al. (2008)                   |
| Gender dimensions of effects | A decrease in women income and stressful social life Mosquito-borne diseases, tick-borne diseases (e.g. malaria, dengue) and air pollution related mortality and morbidity | Pouliotte et al. (2009) |
| Increase of climate extreme related disease and sickness |                                                                                        | Rashid et al. (2013)                 |

Table 2: Community-led adaptation actions of the Bangladeshi coastal communities

| Adaptation sectors       | Description of adaptation                                                                 | Sources                              |
|--------------------------|----------------------------------------------------------------------------------------|--------------------------------------|
| (1) Livelihood           |                                                                                        |                                      |
| Changing rice crop farming to non-rice farming | Farming of different varieties of crops, cultivation of jute, wheat, plum and different types of pulses (i.e., Malaysia etc.) | Sarkar et al. (2011)                 |
| Migrating for jobs mainly to Middle | Field visits, observations and discussion with local communities by author | Field visits, observations and discussion with local communities by author |
| Increasing involvement in a variety of income sources | Earning money by wage labour, small business, construction works and livestock farming Selling land and taking loan (especially poor households) | Alam et al. (2012) |
| Gender dimensions        | Women are forced to take difficult jobs outside their comfort zone.                    | Abedin et al. (2013)                 |
| Obtaining support from relatives and social networks | Support by relatives and social networks to offset losses and to cope with devastations | Questionnaire surveys and FGDs       |
| Raising homestead and plinth | Low-lying coastal and island inhabitants often raise homestead and plinth much higher than mainland people to mitigate severe effects of coastal flooding | Alam (2003a)                         |
| Planting trees           | Planting trees around the house to reduce the intensity of storm surge attack          | Alam (2003b)                         |
| Modifying of houses      | Building a special tent-type of shed for those who have lost their houses               | Alam and Collins (2010)              |
| Changing house locations | - The changes of housing locations from the coast of offshore island to inner part of the island or migration to the adjacent mainland - Those people changes house to the adjacent mainland mostly able to manage settlement in unstable slope of hills, non-habited forest hills, coastal and river margins in the adjacent mainland or cities these areas otherwise unused and publicly owned | Field visits, observations and discussion with local communities by author |
| (2) Human habitations    |                                                                                        |                                      |
| Adopting household coping strategies | Season specific household levels strategies preventing sickness and diseases from extreme heat, cold and precipitation | Haque et al. (2013)                  |

198
Climate change adaptation may be divided into two categories. These are: Institution led adaptation strategies and community led adaptation strategies. This research reports three main sectors (Table 2) of adaptations (i.e., livelihood, human habitation and health) undertaken by communities, which were adopted as responses to tropical cyclone hazards, salinity intrusion into inland areas and other extreme climatic conditions. Apart from the initiatives taken by the national authorities and by non-governmental organizations, coastal community members have taken it upon themselves to find ways to adapt to the heightened risk of climate-related natural disasters. The review suggests that hazard-affected people have employed a variety of short-term and long-term actions to cope with disastrous conditions (Table 2). However, migration is one of the most common adaptation strategies following a disaster, primarily as a result of lost livelihood and the fear of the recurrence of another such calamity (Brook and Paul, 2003). Focus group discussions and field visits revealed that many coastal communities members—particularly those living on daily earnings who own neither land nor other property—had change their residence from the offshore islands, which they had judged to be insecure, to areas on the mainland, which they had presumed to be more safe (Fig. 3).

**Community Resilience to Climate Change**

Community resilience to climate change implies that the return of the functions of life and livelihoods of climatic stress affected community to a normal standard of living with the observed changes in climate and/or future abrupt changes in climate. The concept of resilience needs to be understood in three ways for better policy implications (Tanner *et al.*, 2014). First, it is important to identify its ‘contested nature’. The term resilience depends on differential ‘social values’ we prioritize and how resources are to be allocated to sustain it (O’Brien and Wolf, 2010). The execution of resilience concept may depend on several factors: (1) Types of activities; (2) to whom these to be implemented; (3) agents of decision-making; and (4) cultural context of implementation (Cote and Nightingale, 2012). Second, it needs to be considered how activities and institutions determine political economy of climate change resilience. This allows us to understand who are going to be benefitted by resilience activities, power relation in implementing

---

**Fig. 3**: Location of highly vulnerable areas to tropical cyclones. The yellow solid arrows show the flow direction of disaster-induced migration from the offshore islands to the mainland of Bangladesh. CC = Chittagong City, NK = Noakhali
activities, distribution of benefits, varying access to resources and concurrent inequality in society (Béné et al., 2012; Beymer-Farris et al., 2012). Third, climate resilience should be considered by considering varying level of climate impacts and capacity of different social groups to respond to climate change. The factors of impact and response to climate change may include “levels of on-the-ground social inequality, rights and unequal access to resources, poverty, poor infrastructure, lack of representation and inadequate systems of social protection, planning and risk management” (Tanner et al., 2014).

There is less understanding of community resilience to climate change. The reason for this is that the lack of understanding difference between community led autonomous and institution led imposed climate resilience activities. One example of community led or autonomous climate resilience activity is that the Bangladeshi coastal communities are by generations used to planting trees around the house to reduce the intensity of storm surge attack. One the other hand, the local communities are also transforming their rice farming land into mango orchard with the support of external organizations. However, in the past it is documented that external programmes did not bring much positive impact on local coping strategies with disasters in Bangladesh (Alam and Collins, 2010; Haque and Zaman, 1993). Although it seems that community led resilience activities in responding to tropical cyclones are more acceptable, these would require further validation to test their sustainability.

Indeed, firsthand evidence from coastal Bangladesh-an area frequently affected by tropical cyclones, riverbanks and coastal erosion-indicates that near-distance and far distant out-migration is a continuous adaptation action. The firsthand evidence was collected through frequent field visits and informal discussions with local communities in varying type of hazard prone areas of Bangladesh. Some people migrating from the offshore islands form squatter settlements along the unstable hill slopes in and adjacent to the Chittagong City (Fig. 4). Torrential rainfall in the deforested hills in Chittagong City in June 2007 caused landslides that affected 2,680 families and claimed 137 lives. An analysis of the settlement history of the victims of the landslides found that they had migrated from the offshore island areas to the unstable slopes in the Chittagong City hillside. Three-quarters of those who had migrated to these unstable areas had previously lost their houses as a result of the April 1991 cyclone or due to coastal erosion. Of those who perished in the 2007 landslides, the death toll for women and children far exceeded that of adult males (Chisty, 2014).

**Conclusion**

The research suggests that the Bangladeshi coastal community is taking continuous adaptation actions to survive the slow onset and sudden changes in climate conditions. Human induced climate change is now undeniable. A growing number of researches from around the world has evidenced symptoms and impacts of climate change (CCC, 2009; Khan et al., 2011; Luetz, 2013). Climate change and its associated impacts are experienced through livelihood changes (i.e. decrease of rice production, fish catch in the Bay of Bengal and Bangladesh coast, decrease in crop varieties due to intrusion of saline water and monoculture, etc.), changes in human settlement (i.e. forced migration from the coast to the inland Bangladesh and to adjacent Indian regions) health and wellbeing (i.e. malnutrition, safe drinking water, a decrease in women income and stressful social life, increase of climate extreme related disease and sickness, etc.) of the Bangladeshi coastal communities. The Bangladeshi coastal communities are adopting self-instinct adaptation strategies to these climatic impacts. These include changing rice crop farming to non-rice farming, migrating to other countries for livelihood purposes, raising homestead and plinth, modification of houses, season specific household levels strategies preventing sickness and diseases from extreme heat, cold and precipitation, etc. Changing location of houses from hazard-prone coastal areas to the mainland is one form of adaptation action the coastal community has undertaken. However, the ongoing research on disaster-induced migration indicates that the migrants were not able to obtain secure land but rather settled in an area that is, itself, prone to another form of disaster. The specific audiences of this research will be research academics and institutions, Government of Bangladesh, Non-Governmental Organizations in Bangladesh along with
other international developmental organizations working on disaster risk reduction, climate change adaptation and sustainable development sectors in Bangladesh and elsewhere in the world.

Acknowledgment

Dr Edris Alam thanks the University of Chittagong for approval of higher study leave at UNSW Australia. He acknowledges substantial input and correction received from anonymous reviewers and friends who wanted to be anonymous. Thanks are extended to the Disaster Action and Development Organisation (DADO), Bangladesh for helping data collection in Bangladesh.

Ethics

There are no ethical issues associated with this paper as all the respondents of interviews remain anonymous and the participants who contributed data/information did so in full consciousness of the fact of what the research was about.
