Abstract
We develop an exact method for computing the Casimir energy between arbitrary compact objects, both with boundary conditions for a scalar field and dielectrics or perfect conductors for the electromagnetic field. The energy is obtained as an interaction between multipoles, generated by quantum source or current fluctuations. The objects’ shape and composition enter only through their scattering matrices. The result is exact when all multipoles are included, and converges rapidly. A low-frequency expansion yields the energy as a series in the ratio of the objects’ size to their separation. As examples, we obtain this series for two spheres with Robin boundary conditions for a scalar field and dielectric spheres for the electromagnetic field. The full interaction at all separations is obtained for spheres with Robin boundary conditions and for perfectly conducting spheres.

1. Introduction
Casimir forces arise when the quantum fluctuations of a scalar, vector or even fermion field are modified by the presence of static or slowly changing external objects [1]. The objects can be modeled by boundary conditions that they place on the fluctuating field \( \phi \), by an external field, \( \sigma \), to which \( \phi \) couples [2], or, in the case of electromagnetism, by a material with space and frequency dependent dielectric and magnetic properties. The Casimir energy is the difference between the energy of the fluctuating field when then objects are present and when the objects are removed to infinite separation.

The advent of precision experimental measurements of Casimir forces [3] and the possibility that they can be applied to nanoscale electromechanical devices [4, 5] has stimulated interest in developing a practical way to calculate the dependence of Casimir energies on the
shapes of the objects. Many geometries have been analyzed over the years, but the case of compact objects has proved rather difficult. In a recent paper, we described a new method that makes possible accurate and efficient calculations of Casimir forces and torques between any number of compact objects. The method applies to electromagnetic fields and dielectrics as well as perfect conductors. It also applies to other fields, such as scalar and Dirac, and to any boundary conditions. In this approach, the Casimir energy is given in terms of the fluctuating field’s scattering amplitudes from the individual objects, which encode the effects of the shape and boundary conditions. The scattering amplitudes are known analytically in some cases and numerically in others. If the scattering amplitudes are known, then the method can be applied from asymptotically large separation down to separations that are a small fraction of the dimension of the objects. Results at large separations are obtained using low frequency and low angular momentum expansions of scattering amplitudes. The coefficients multiplying the successive orders in inverse separation can be identified with increasingly detailed characteristics of the objects. At small separations the manipulation of large matrices, whose dimensions grow with angular momentum, eventually slows down the calculation. However at these distances other methods, notably the ‘proximity force approximation’ (PFA), apply. Thus it is now possible to obtain an understanding of Casimir forces and torques at all separations for compact objects.

The aim of this talk is to provide a pedagogical introduction to our methods by treating in detail the simplest case, a scalar field obeying a boundary condition on a sharp surface. The complications of electromagnetism and smoothly varying dielectrics were already introduced in [6] and are discussed here briefly. Our result for the Casimir energy is remarkably simple. For a complex scalar field in the presence of two objects it takes the form

$$E_{12}[C] = \frac{\hbar c}{\pi} \int_{0}^{\infty} d\kappa \ln \det(I - T^{1}\underline{U}\cap T^{2}\underline{U})$$

where the determinant is over the partial wave indices on transition matrices $T^{\alpha}$ and translation matrices $\underline{U}^{\alpha\beta}$ and the integral is over $\kappa = -i\omega/c$, the imaginary wavenumber. For a (real) electromagnetic field the result has the same form with an additional factor of $1/2$ and the appropriate matrices for scattering and propagation of electromagnetic waves. In sections 4 and 5, the usefulness of this result is demonstrated through several specific applications for scalar and electromagnetic fields, respectively.

The force between atoms at asymptotically large distances was computed by Casimir and Polder and related to the atoms’ polarizabilities. For compact objects, such as two spheres, Feinberg and Sucher generalized this work to include magnetic effects. Earlier studies of the Casimir force between compact objects include a multiple reflection formalism, which in principle could be applied to perfect conductors of arbitrary shape. A formulation of the Casimir energy of compact objects in terms of their scattering matrices, for a scalar field coupled to a dielectric background, is introduced in [11], where it is suggested that it can also be extended to the EM case.

Conceptually, the effect of geometry and shape is difficult to study due to the non-additivity of fluctuation forces. Explicit consequences of this non-additivity and also non-monotonic changes in the force have been recently predicted for a pair of cylinders next to planar walls. This behavior has been interpreted in terms of collective charge fluctuations inside the bodies.

For non-planar, deformed plates, a general representation of the Casimir energy as a functional determinant of a matrix that describes reflections at the surfaces and free propagation

This presentation is based on work performed in collaboration with N Graham and M Kardar. For a complete exposition, see [6, 7].
between them has been developed in [14]. An equivalent representation has been applied to perturbative computations in the case of rough [15] and corrugated plates with perfect [16, 17] and finite conductivity [18]; for a review of the latter results see [19].

Recently Gies et al [20] used numerical methods to evaluate the Casimir force between two Dirichlet spheres for a scalar field, over a range of subasymptotic separations, and in other open geometries such as a plate and a cylinder [21] or finite plates with edges [22]. Bulgac and collaborators [23] applied scattering theory methods to the same scalar Dirichlet problem and obtained results over a wide range of separations. The only explicit calculations for subasymptotic distances up to now have been for a scalar field obeying Dirichlet boundary conditions on two spheres, a sphere and a plate [23] and for electromagnetic fields for a plate and a cylinder [24–27] and two perfectly conducting spheres [6].

2. Casimir energy from the functional integral: scalar field

In this section, we review formalism essential for our work that is based on the functional integral approach of [16, 28, 29].

2.1. Functional integral formulation

We consider a complex quantum field, \( \phi(x, t) \), which is defined over all space and constrained by boundary conditions \( C \) on a set of fixed surfaces \( \Sigma_\alpha \), for \( \alpha = 1, 2, \ldots, N \), but is otherwise non-interacting. We assume that the surfaces are closed and compact and refer to their interiors as ‘objects’. Our starting point is the functional integral representation for the trace of the propagator, \( \text{Tr} e^{-iH_C T/\hbar} \) [30],

\[
\text{Tr} e^{-iH_C T/\hbar} = \int [D\phi]_C e^{iS[\phi]} \equiv Z[C], \tag{2.1}
\]

where the subscript \( C \) denotes the constraints imposed by the boundary conditions\(^5\). The integral is over all field configurations that obey the boundary conditions and are periodic in a time interval \( T \). \( S[\phi] \) is the action for a free complex field,

\[
S[\phi] = \int_0^T dt \int dx \left( \frac{1}{c^2} |\partial_t \phi|^2 - |\nabla \phi|^2 \right), \tag{2.2}
\]

where the \( x \)-integration covers all space\(^6\).

The ground-state energy can be projected out of the trace in equation (2.1) by setting \( T = -i\lambda/c \) taking the limit \( \lambda \to \infty \),

\[
\mathcal{E}_0[C] = -\lim_{\lambda \to \infty} \frac{\hbar c}{\Lambda} \ln \left( \text{Tr} e^{-iH_C \Lambda/\hbar c} \right) = -\lim_{\lambda \to \infty} \frac{\hbar c}{\Lambda} \ln Z[C], \tag{2.3}
\]

and the Casimir energy is obtained by subtracting the ground-state energy when the objects have been removed to infinite separation,

\[
\mathcal{E}[C] = -\lim_{\Lambda \to \infty} \frac{\hbar c}{\Lambda} \ln \left( Z[C]/Z_\infty \right). \tag{2.4}
\]

In the standard formulation, the constraints are implemented by boundary conditions on the field \( \phi \) at the surfaces \( \{\Sigma_\alpha\} \). The usual choices are Dirichlet \( \phi = 0 \), Neumann \( \partial_n \phi = 0 \) or...
mixed (Robin) $\phi - \lambda \partial_n \phi = 0$, where $\partial_n$ is the normal derivative pointing out of the objects. To be specific, we first consider Dirichlet boundary conditions. The extension to the Neumann case is presented in [7]. As noted in the introduction, the only effect of the choice of boundary conditions is to determine which $T$-matrix appears in the functional determinant, equation (1.1).

Since the constraints on $\phi$ are time independent, the integral over $\phi(x, t)$ may be written as an infinite product of integrals over Fourier components,

$$\int [D\phi]_c = \prod_{n=-\infty}^{\infty} [D\phi_n(x)]_c, \quad (2.5)$$

where

$$\phi(x, t) = \sum_{n=-\infty}^{\infty} \phi_n(x) e^{2\pi i n/T}, \quad (2.6)$$

and the logarithm of $Z$ becomes a sum,

$$\ln Z[C] = \sum_{n=-\infty}^{\infty} \ln \left\{ \int [D\phi_n(x)]_c \exp \left[ \frac{T}{\hbar} \int dx \left( \frac{2\pi n}{cT} \right)^2 |\phi_n(x)|^2 - |\nabla \phi_n(x)|^2 \right] \right\}. \quad (2.7)$$

As $T \to \infty$, $\sum_k$ can be replaced by $\frac{cT}{\pi} \int_{-\infty}^{\infty} dk$, where $k = 2\pi n/(cT)$ and $\phi_n(x)$ is replaced by $\phi(x, k)$. Combining the positive and negative $k$-integrals gives

$$\ln Z[C] = \frac{cT}{\pi} \int_{-\infty}^{\infty} dk \ln \left\{ \int [D\phi(k)]_c \exp \left[ \frac{i T}{\hbar} \int dx (k^2 |\phi(x, k)|^2 - |\nabla \phi(x, k)|^2) \right] \right\}$$

$$= \frac{cT}{\pi} \int_{0}^{\infty} dk \ln \mathcal{Z}_c(k), \quad (2.8)$$

where

$$\mathcal{Z}_c(k) = \int [D\phi(x, k)]_c \exp \left[ \frac{i T}{\hbar} \int dx (k^2 |\phi(x, k)|^2 - |\nabla \phi(x, k)|^2) \right]. \quad (2.9)$$

is the functional integral at fixed $k$.

To extract the Casimir energy, we use $T = -i \Lambda/c$ and Wick rotate the $k$-integration ($k = i\kappa$ with $\kappa > 0$). Using equation (2.4), we obtain

$$\mathcal{E}[C] = -\frac{\hbar c}{\pi} \int_{0}^{\infty} d\kappa \ln \frac{\mathcal{Z}_c(i\kappa)}{\mathcal{Z}_c(0)}. \quad (2.10)$$

Here $\mathcal{Z}_c(0)$ is given by the Euclidean functional integral

$$\mathcal{Z}_c(0) = \int [D\phi(x, 0)]_c \exp \left[ -\frac{T}{\hbar} \int dx (k^2 |\phi(x, 0)|^2 + |\nabla \phi(x, 0)|^2) \right]. \quad (2.11)$$

It remains to incorporate the constraints directly into the functional integral using the methods of [31, 28]. Working in Minkowski space, we consider the fixed frequency functional integral, $\mathcal{Z}_c(k)$ (and suppress the label $k$ on the field $\phi$). Following [31, 28], we implement the constraints in the functional integral by means of a functional $\delta$-function. For Dirichlet boundary conditions the constraint reads

$$\int [D\phi(x)]_c = \int [D\phi(x)]_c \prod_{\alpha=1}^{N} \int [D\phi_{\alpha}(x)] \exp \left[ \frac{T}{\hbar} \int \mathcal{L}_{\alpha}(\phi(x) + c.c.) \right]. \quad (2.12)$$

7 A more careful treatment of the rotation of the integration contour to the imaginary axis is necessary in the presence of bound states.
where the functional integration over $\phi$ is no longer constrained. Other boundary conditions can be implemented similarly. In the resulting functional integral

$$Z_C(k) = \prod_{\alpha=1}^N \int [D\varrho_\alpha(x)] \int [D\phi(x)] \exp \left[ \frac{i}{\hbar} \left( \int dx(k^2|\phi(x)|^2 - |\nabla\phi(x)|^2 \right) + \sum_{\alpha} \int_{\Sigma_\alpha} dx(\varrho_\alpha^* \phi(x) + \text{c.c.}) \right]$$

$$\equiv \prod_{\alpha=1}^N \int [D\varrho_\alpha(x)] \int [D\phi(x)] \exp \left( \frac{i}{\hbar} \tilde{S}[\phi, \varrho] \right),$$

(2.13)

the fields fluctuate without constraint throughout space and the sources $\{\varrho_\alpha\}$ fluctuate on the surfaces. We denote the new ‘effective action’ including both the fields and sources by $\tilde{S}[\phi, \varrho]$.

### 2.2. Performing the integral over $\phi$

We start with the expression for the fixed-$k$ functional integral, equation (2.13). For any fixed sources, $\{\varrho_\alpha\}$, there is a unique classical field, $\phi_{cl}[\varrho]$, that is the solution to $\delta \tilde{S}[\phi, \varrho] / \delta \phi(x) = 0$. The classical theory defined by $\tilde{S}[\phi, \varrho]$, describes a complex scalar field coupled to a set of sources on the surfaces, and is a generalization of electrostatics. By analogy with electrostatics, the field $\phi$ is continuous throughout space, but its normal derivative jumps by $\varrho_\alpha(x)$ across $\Sigma_\alpha$. Indeed, the classical equations of motion that follow from $\delta \tilde{S} / \delta \phi = 0$ are

$$\nabla^2 \phi_{cl}(x) = 0, \quad \text{for } x \notin \Sigma_\alpha,$$

$$\Delta \phi_{cl}(x) = 0, \quad \text{for } x \in \Sigma_\alpha,$$

$$\Delta \partial_n \phi_{cl}|_x = \varrho_\alpha(x), \quad \text{for } x \in \Sigma_\alpha,$$

(2.14)

where $\Delta \phi = \phi_{in} - \phi_{out}$ and $\Delta \partial_n \phi = \partial_n \phi|_{in} - \partial_n \phi|_{out}$. The subscripts ‘in’ and ‘out’ refer to the field inside and outside the bounding surface $\Sigma_\alpha$. As before, all normals point out of the compact surfaces. The solution to equation (2.14) is unique up to solutions of the homogeneous equations, which we exclude by demanding that $\phi_{cl}$ vanish when the $\{\varrho_\alpha\} = 0$.

Continuing the analogy with electrostatics, we can write the classical field in terms of the free Green’s function and the sources,

$$\phi_{cl}(x) = \sum_{\beta} \int_{\Sigma_\beta} dx' G_0(x, x', k) \varrho_\beta(x'),$$

(2.15)

where the free Green’s function is given by

$$G_0(x, x', k) = \frac{e^{ik|x-x'|}}{4\pi|x-x'|} = \frac{ik}{4\pi} \sum_{lm} j_l(kr) h_l^{(1)}(kr) Y_{lm}(\hat{x}) Y_{lm}^*(\hat{x}')$$

(2.16)

where the notations $r, r'$ refer to whichever of $r, r'$ is the smaller (larger).

To compute the functional integral over $\phi$, we first decompose $\phi$ into the classical part given by equation (2.15) and a fluctuating part,

$$\phi(x) = \phi_{cl}(x) + \delta \phi(x).$$

(2.17)
Then, because the effective action, \( \tilde{S} \), is quadratic in \( \phi \), the \( \delta \phi \) dependent terms are independent of \( \phi_{cl} \),

\[
\tilde{S}_c(k) = \prod_{a=1}^{N} \int [D\varrho_a(x)] e^{i \frac{\bar{h}}{2} \int [D\delta \phi(x)]} \int [D\varrho(x)] \exp \left[ \frac{i T}{\hbar} \int dx (k^2 |\delta \phi(x)|^2 - |\nabla \delta \phi(x)|^2) \right].
\]

(2.18)

The classical action can be simplified by using the equations of motion, equation (2.14), which make it possible to express the action entirely in terms of integrals over the surfaces \( \{ \Sigma_a \} \),

\[
\tilde{S}_{cl}(\varrho) = \frac{1}{2} \sum_{\alpha} \int_{\Sigma_\alpha} \text{d}x (\varrho_\alpha^*(x)\phi_{cl}(x) + \text{c.c.}),
\]

(2.19)

where \( \phi_{cl}(x) \) is understood to be a functional of the sources \( \varrho_a \).

The functional integral over \( \delta \phi \) is independent of the classical field \( \phi_{cl} \) and defines the energy of the unconstrained vacuum fluctuations of \( \phi \). This term is divergent, or, more precisely, depends on some unspecified ultraviolet cutoff. However it can be discarded because it is independent of the sources and therefore common to \( Z_c \) and \( Z_\infty \). Note that this result is an explicit demonstration of the contention of [32]: the Casimir force has nothing to do with the vacuum fluctuations of \( \phi \), but is instead a consequence of the interaction between fluctuating sources in the materials. It is therefore not directly relevant to the fluctuations that are conjectured to be associated with the dark energy.

From equation (2.15) it is clear that the solution to equation (2.14) obeys the superposition principle: \( \phi_{cl}(x) \) is a sum of contributions from each of the sources,

\[
\phi_{cl}(x) = \sum_\beta \phi_\beta(x),
\]

(2.20)

where \( \phi_\beta \) satisfies equation (2.14) with all sources set equal to zero except for \( \varrho_\beta \). So the action can be expressed as a double sum over surfaces and over contributions to \( \phi_{cl} \) generated by different objects. This leaves a partition function, \( \tilde{S}_c(k) \), of the form

\[
\tilde{S}_c(k) = \prod_{a=1}^{N} \int [D\varrho_a(x)] \exp \left[ \frac{i T}{\hbar} \sum_{\alpha,\beta} \int_{\Sigma_a} \text{d}x (\varrho_\alpha^*(x)\phi_\beta(x) + \text{c.c.}) \right]
\]

(2.21)

to be evaluated.

2.3. Evaluation of the classical action

The classical action in equation (2.21) contains two qualitatively different terms, the interaction between different sources, \( \alpha \neq \beta \), and the self-interaction of the source \( \varrho_\beta \). Both can be expressed as functions of the multipole moments of the sources on the surfaces.

2.3.1. Interaction terms: \( \alpha \neq \beta \). Consider the contribution to the action from the field, \( \phi_\beta \), generated by the source, \( \varrho_\beta \), integrated over the surface \( \Sigma_\beta \),

\[
\tilde{S}_{\beta\beta} = \frac{1}{2} \int_{\Sigma_\beta} \text{d}x_\beta (\varrho_\beta^*(x_\beta)\phi_\beta(x_\beta) + \text{c.c.}),
\]

(2.22)

where the subscript \( \alpha \) on \( x_\alpha \) indicates that the integration runs over coordinates measured relative to the origin of object \( \alpha \). The field \( \phi_\beta(x_\beta) \), measured relative to the origin of object \( \beta \), can be represented as an integral over its sources on the surface \( \Sigma_\beta \) as in equation (2.15). Since every point on \( \Sigma_\beta \) is outside of a sphere enclosing \( \Sigma_\beta \), the partial wave representation
of $G_0$ simplifies. The coordinate $x_\alpha$ is always associated with $x_\beta$ and $x_\alpha$ is identified with $x'_\beta$, so equation (2.15) can be written as

$$\phi_{\beta}(x_\beta) = i k \sum_{l,m} h_1^{(1)}(kr_\beta) Y_{lm}(\hat{x}_\beta) \int_{E_\beta} dx'_\beta j_l(kr'_\beta) Y^*_{lm}(\hat{x}'_\beta) \rho_\beta(x'_\beta). \quad (2.23)$$

Note that the arguments of the Bessel functions and spherical harmonics are all defined relative to the origin $O_\beta$. In particular, $r'_\beta$ and $\hat{x}'_\beta$ are the radial and angular coordinates relative to $O_\beta$ corresponding to a point $x'$ on the surface $\Sigma_\beta$. The integrals over $\Sigma_\beta$ define the multipole moments of the source $\rho_\beta$, which will be our final quantum variables,

$$Q_{\beta,lm} = \int_{\Sigma_\beta} dx_\beta j_l(kr_\beta) Y^*_{lm}(\hat{x}_\beta) \rho_\beta(x_\beta), \quad (2.24)$$

so that

$$\phi_{\beta}(x_\beta) = i k \sum_{l,m} Q_{\beta,lm} h_1^{(1)}(kr_\beta) Y_{lm}(\hat{x}_\beta). \quad (2.25)$$

The field $\phi_{\beta}$ viewed from the surface $\Sigma_\alpha$ is a superposition of solutions to the Helmholtz equation that are regular at the origin $O_\alpha$. Using translation formulae, summarized in [33], the field generated by object $\Sigma_\beta$ can be written as function of the coordinate $x_\alpha$, measured from the origin $O_\alpha$, as

$$\phi_{\alpha}(x_\alpha) = i k \sum_{l,m} Q_{\alpha,lm} \sum_{l'm'} U_{\alpha\beta}^{l'm'} Q_{\beta,lm} + \text{c.c.} \quad (2.26)$$

The matrices $U_{l'm'l'm'}$ are shape and boundary condition independent and represent the interaction between the multipoles. This result, in turn, can be substituted into the contribution $\tilde{S}_{\alpha\beta}$ to the action, leading to the simple result

$$\tilde{S}_{\alpha\beta}[Q_{\alpha}, Q_{\beta}] = \frac{i k}{2} \sum_{l,m,l',m'} Q_{\alpha,lm}^* U_{l'm'l'm'}^\beta Q_{\beta,lm} + \text{c.c.} \quad (2.27)$$

Note that the contributions to the action that couple fields and sources on different objects make no reference to the particular boundary conditions that characterize the Casimir problem. They depend only on the multipole moments of the fields and on the geometry through the translation matrix $U_{l'm'l'm'}$.

2.3.2. Self-interaction terms. We turn to the terms in $\tilde{S}_{\alpha}$ where the field and the source both refer to the same surface, $\Sigma_\alpha$,

$$\tilde{S}_\alpha[\phi_\alpha] = \frac{1}{2} \int_{\Sigma_\alpha} dx (\phi_\alpha^*(x) \phi_\alpha(x) + \text{c.c.}) \quad (2.28)$$

For the self-interactions terms, we only use the coordinate system with origin $O_\alpha$ inside the surface $\Sigma_\alpha$, and hence drop the label $\alpha$ on the coordinates in this section. Since $\phi_\alpha(x)$ is continuous across the surface, we can regard the $\phi_\alpha$ in equation (2.28) as the field inside $\Sigma_\alpha$, $\phi_{in,a}$, which is a solution to Helmholtz’s equation that must be regular at the origin $O_\alpha$,

$$\phi_{in,a}(x) = \sum_{l,m} \phi_{in,lm} j_l(kr) Y_{lm}(\hat{x}). \quad (2.29)$$

Substituting this expansion into equation (2.28), we obtain

$$\tilde{S}_\alpha[\phi_\alpha] = \frac{1}{2} \sum_{l,m} (\phi_{in,lm} Q_{a,lm}^* + \text{c.c.}), \quad (2.30)$$

where $Q_{a,lm}$ are the multipole moments of the sources, defined in the previous subsection.
Finally, we relate $\phi_{a,lm}$ back to the multipole moments of the source to get an action entirely in terms of $Q_{a,lm}$. The field $\phi_{a,\text{out}}$ at points outside of $\Sigma_a$ obeys Helmholtz’s equation and must equal $\phi_{a,\text{in}}$ on the surface $S$. Therefore it can be written as $\phi_{a,\text{in}}$ plus a superposition of the regular solutions to the Helmholtz equation that vanish on $\Sigma_a$,

$$\phi_{a,\text{out}}(x) = \phi_{a,\text{in}}(x) + \Delta \phi_a(x)$$

$$= \phi_{a,\text{in}}(x) + \sum_{lm} \chi_{a,lm} \left( j_l(kr) Y_{lm}(\hat{x}) + \sum_{l'm'} T_{lm'lm}^a(k) h_{l'}^{(1)}(kr) Y_{l'm'}(\hat{x}) \right). \quad (2.31)$$

The second term, $\Delta \phi_a$, vanishes on $\Sigma_a$ because $T_{lm}^a$ is the scattering amplitude for the Dirichlet problem.

The field we seek is generated in response to the sources and therefore falls exponentially (for $k$ with positive imaginary part) as $r \to \infty$. Therefore the terms in equation (2.31) that are proportional to $j_l(kr)$ must cancel. Comparing equation (2.31) with equation (2.29), we conclude that $\chi_{a,lm} = -\phi_{a,lm}$, and therefore

$$\phi_{a,\text{out}}(x) = -\sum_{lm} \phi_{a,lm} \sum_{l'm'} T_{lm'lm}^a(k) h_{l'}^{(1)}(kr) Y_{l'm'}(\hat{x}). \quad (2.32)$$

On the other hand, $\phi_{a,\text{out}}(x)$ can be expressed as an integral over the source as in equation (2.15),

$$\phi_{a,\text{out}}(x) = \int_{\Sigma_a} d\mathbf{x}' g_0(x, \mathbf{x}', k) \phi_a(\mathbf{x}'). \quad (2.33)$$

Using the partial wave expansion for the free Green’s function, equation (2.16), we find

$$\phi_{a,\text{out}}(x) = i k \sum_{l'm'} Q_{a,l'm'} h_{l'}^{(1)}(kr) Y_{l'm'}(\hat{x}), \quad (2.34)$$

and comparing with equation (2.32), we see that

$$ik Q_{a,l'm'} = -\sum_{lm} T_{lm'lm}^a(k) \phi_{a,lm}$$

or

$$\phi_{a,lm} = -ik [T^a]^{-1}_{lm'lm} Q_{a,l'm'}, \quad (2.35)$$

where $[T^a]^{-1}$ is the inverse of the Dirichlet transition matrix $T^a$. When this is combined with equation (2.30), we obtain the desired expression for the self-interaction contribution to the action,

$$\tilde{S}_a[Q_a] = -ik \sum_{lm'lm} Q_{a,lm} [T^a]^{-1}_{lm'lm} Q_{a,l'm'} + \text{c.c.} \quad (2.36)$$

2.4. Evaluation of the integral over sources

Combining equation (2.36) with equation (2.27), we obtain an expression for the action that is a quadratic functional of the multipole moments of the sources on the surfaces. The functional integral equation (2.21) can be evaluated by changing variables from the sources, $\{Q_a\}$ to the multipole moments. The functional determinant that results from this change of variables can be discarded because it is a common factor which cancels between $Z_C$ and $Z_{\infty}$. To compute
the functional integral we analytically continue to imaginary frequency, $k = i\kappa, \kappa > 0,

\begin{align*}
\mathcal{Z}_c(i\kappa) &= \prod_{a=1}^{N} \int[dQ_a] \exp \left\{ -\frac{k T}{2 \hbar} \sum_a Q_a^* T_{a}^{\alpha} T^{-1} \frac{k T}{2 \hbar} \sum_{a \neq \beta} Q_{a \beta} + c.c. \right\},
\end{align*}

(2.37)

where we have suppressed the partial wave indices. The functional integral equation (2.37) yields the inverse determinant of a matrix $M_{c\beta}^{\alpha\beta}$ that is composed of the inverse transition matrices $T_{a}^{\alpha}$ on its diagonal and the translation matrices $U_{a\beta}^{\alpha\beta}$ on the off-diagonals,

\begin{align*}
M_{c\beta}^{\alpha\beta} &= [T_{a}^{\alpha}]^{-1} \delta_{a\beta} - U_{a\beta}^{\alpha\beta} (1 - \delta_{a\beta}).
\end{align*}

Finally, we substitute into equation (2.10) to obtain the Casimir energy

\begin{align*}
\mathcal{E}[C] &= \frac{\hbar c}{\pi} \int_0^\infty \mathrm{d}k \ln \frac{\det M_c(i\kappa)}{\det M_{\infty}(i\kappa)},
\end{align*}

(2.39)

where the determinant is taken with respect to the partial wave indices and the object indices $\alpha, \beta$, and $M_{c\beta}^{\alpha\beta} = [T_{a}^{\alpha}]^{-1} \delta_{a\beta}$ is the result of removing the objects to infinite separation, where the interaction effects vanish.

In the special case of two interacting objects equation (2.39) simplifies to

\begin{align*}
\mathcal{E}_2[C] &= \frac{\hbar c}{\pi} \int_0^\infty \mathrm{d}k \ln \det (1 - T_1 U_1^{12} T_2 U_2^{21}),
\end{align*}

(2.40)

where $T_{\alpha}, \alpha = 1, 2$ and $U_{a\beta}^{\alpha\beta}$ are the transition and translation matrices for the two objects.

3. Casimir energy from the functional integral: electromagnetic field

In this section, we provide a brief description of the generalization of the concepts from the previous section to electromagnetic fields [6]. Here we start directly with a formulation in terms of sources, the current and charge densities $J, \varrho$. Using that the EM gauge and scalar potential $[A(x, t), \Phi(x, t)]$ are given by

\begin{align*}
[A(x, t), \Phi(x, t)] &= \int \mathrm{d}x' G_0(x, x')[J(x'), \varrho(x')],
\end{align*}

(3.1)

where now $G_0(x, x') = e^{ik|x-x'|}/(4\pi |x-x'|)$, the action $S[J] = \int (dk/4\pi) (S_t[J] + S_\Phi[J])$ for the currents densities, defined inside the objects, can be written as

\begin{align*}
S_t[J_a] &= \frac{1}{2} \int \mathrm{d}x \mathrm{d}x' \sum_{a\beta} J_{a}^*(x) G_0(x, x') J_{\beta}(x'),
\end{align*}

(3.2)

where $G_0(x, x') = G_0(x, x') - \frac{1}{2} \nabla \otimes \nabla' G_0(x, x')$ is the tensor Green’s function. This is the analogous expression to the one for a scalar field in equation (2.21) with the solution of equation (2.15) substituted. Next we must constrain the currents to be induced sources that depend on shape and material of the objects. Formally this is achieved by integrating over currents, inserting constraints to ensure that the currents in vacuum simulate the correct induction of microscopic polarization $P_a$ and magnetization $M_a$ (from all multipoles) inside the dielectric objects in response to an incident wave.

Let us consider one object. First, the induced current is $J_a = -ik P_a + \nabla \times M_a$, and since $P_a = (\epsilon_a - 1)E_a, M_a = (1 - 1/\mu_a)B_a$ it can be expressed in terms of the total fields $E, B$ inside the object as

\begin{align*}
J_a &= -ik(\epsilon_a - 1)E_a + \nabla \times [(1 - 1/\mu_a)B_a].
\end{align*}

(3.3)
Second, the total field inside the object must consist of the field generated by \( \mathbf{J}_a \) and the incident field \( \mathbf{E}_0([\mathbf{J}_a, \mathbf{S}^\alpha_0], \mathbf{x}) \) that has to impinge on the object to induce \( \mathbf{J}_a \), so that
\[
\mathbf{E}(\mathbf{x}) = \mathbf{E}_0([\mathbf{J}_a, \mathbf{S}^\alpha_0], \mathbf{x}) + i k \int d\mathbf{x}' \mathbf{G}_0(\mathbf{x}, \mathbf{x}') \mathbf{J}_a(\mathbf{x'}). \tag{3.4}
\]

The incident field depends on the current density to be induced and on the scattering matrix \( \mathbf{S}^\alpha_0 \) of the object, which connects the incident wave to the scattered wave. It is fully specified by the multipole moments of \( \mathbf{J}_a \) (see below for details). Substituting equation (3.4) and \( \mathbf{B} = (1/ik) \nabla \times \mathbf{E} \) into equation (3.3) yields a self-consistency condition that constrains the current \( \mathbf{J}_a \). If one writes this condition as \( C^\alpha_0 [\mathbf{J}_a] = 0 \) for each object, the functional integration over the currents constrained this way for all objects yields the partition function
\[
\mathcal{Z} = \int \prod_a d\mathbf{J}_a \prod_{\mathbf{x} \in V_a} \delta(C^\alpha_0 [\mathbf{J}_a(\mathbf{x})]) \exp(i\mathcal{S}[\mathbf{J}_a(\mathbf{x})]). \tag{3.5}
\]

It is instructive to look at two compact objects at a distance \( d \), measured between the (arbitrary) origins \( \mathbf{O}_a \) inside the objects. In this case, the action of equation (3.2) is
\[
\mathcal{S}_k([\mathbf{J}_a]) = \frac{1}{2} \sum_{\alpha, \beta} \int \mathbf{d} \mathbf{x}_a \left[ \mathbf{J}_\alpha^*(\mathbf{x}_a) - \mathbf{J}_\beta(\mathbf{x}_a - \mathbf{d}_\alpha) \right] \cdot \frac{1}{i k} \mathbf{E}_0(\mathbf{x}_a - \mathbf{d}_\alpha) + \frac{1}{2} \sum_{\alpha} \int \mathbf{d} \mathbf{x}_a \left[ \mathbf{J}_\alpha^*(\mathbf{x}_a) \mathbf{G}_0(\mathbf{x}_a, \mathbf{x}_a') \mathbf{J}_\alpha(\mathbf{x}_a') \right], \tag{3.6}
\]

where we have substituted the electric field \( \mathbf{E}_0(\mathbf{x}_a) = i k \int \mathbf{d} \mathbf{x}' \mathbf{G}_0(\mathbf{x}_a, \mathbf{x}_a') \mathbf{J}_\alpha(\mathbf{x}_a') \) and the fields are measured now in local coordinates so that \( \mathbf{x} = \mathbf{O}_a + \mathbf{x}_a \), and \( \mathbf{d}_\alpha = d (-d) \) for \( \alpha = 1(2) \). The off-diagonal terms in equation (3.6) represent the interaction between the currents on the two materials. A natural way to decompose the interaction between charges is to use the multipole expansion. For each body we define magnetic and electric multipoles as
\[
Q_{M,\alpha}^{\text{eff}} \left[ \{ Q_{\beta}^{\alpha, \text{eff}} \} \right] = \frac{1}{2} \sum_{l \geq 1, |m| \leq l, \lambda} \left( Q_{\text{in}}^{\alpha, \text{eff}} U_{\text{in}}^{\alpha, \text{eff}} U_{\text{in}}^{\alpha, \text{eff}} + Q_{\text{in}}^{\alpha, \text{eff}} U_{\text{in}}^{\alpha, \text{eff}} U_{\text{in}}^{\alpha, \text{eff}} + \sum_{\alpha, \beta} Q_{\text{in}}^{\alpha, \text{eff}}[-T_{\text{in}}^{\alpha, \text{eff}}]^{-1} T_{\text{in}}^{\alpha, \text{eff}} \right), \tag{3.8}
\]

with \( Q_{\text{in}}^{\alpha, \text{eff}} = \{ Q_{M,\alpha}^{\alpha, \text{eff}}, Q_{E,\alpha}^{\alpha, \text{eff}} \} \). Formally, this action resembles that for a scalar field. The vector nature of the EM field is reflected by the presence of two different polarizations and corresponding electric and magnetic multipoles. Let us discuss the terms appearing in equation (3.8) and sketch its derivation.

Off-diagonal terms—We need to know the electric fields in equation (3.6) exterior to the source that generates them. They can be represented in terms of the multipoles as \( \mathbf{E}_0(\mathbf{x}_\beta) = -k \sum_{l \geq 1} \sum_{m} Q_{\text{out}}^{\beta, \text{in}}(\mathbf{x}_\beta) \mathbf{Y}_{lm}^\ast(\mathbf{x}_\beta) \) where \( \mathbf{Y}_{lm}^\ast(\mathbf{x}_\beta) \) are outgoing vector solutions of the Helmholtz equation in the coordinates of object \( \beta \). We would like to express the currents
\[
8 \text{ The two components of } \psi_{\text{in}}^\alpha \text{ are given by } 1/k \text{ times the weights for } E- \text{ and } M-\text{multipoles of equation (3.7) with } Y_{lm} \text{ replaced by } Y_{lm}^\ast. \text{ Similarly, } \psi_{\text{out}}^\alpha \text{ have the same expressions upon substituting Bessel by Hankel functions, } j_l \rightarrow h_l^{(1)}.}

\( \mathbf{J}_\text{r}^\alpha \) in equation (3.6) also in terms of multipoles. The difficulty in doing so is that the electric field is expressed in terms of \textit{outgoing} partial waves in the coordinates of object \( \beta \), while according to equation (3.7), the multipoles involve partial waves \( \Psi_{\text{lm}}^\text{reg}(\mathbf{x}_\text{a}) \) that are \textit{regular} at the origin \( \mathcal{O}_\alpha \), in the coordinates of object \( \alpha \). Going from the outgoing to the regular vector solutions and changing the coordinate system involves a translation and change of basis which can be expressed as \( \Psi_{\text{lm}}^\text{reg}(\mathbf{x}_\text{a} \pm \mathbf{d}) = \sum_{l'm'} U_{\text{lm}}^{\alpha l'm'} \Psi_{\text{lm}}^\text{reg}(\mathbf{x}_\text{a}) \) where the universal (shape and material independent) translation matrices \( U_{\text{12}}^\alpha \) and \( U_{\text{21}}^\alpha \) represent the interaction between the multipoles. For fixed \( (\text{lm}) \), \( (l'm') \), they are \( 2 \times 2 \) matrices (magnetic and electric multipoles), and functions of \( kd \) only. Their explicit form is known but not provided here to save space; they fall off with \( kd \) according to classical expectations for the EM field. Then the electric field becomes

\[
\frac{1}{\mu} \mathbf{E}_\alpha(\mathbf{x}_\beta \pm \mathbf{d}) = \sum_{\text{lm}} \phi_{\text{lm}}^\alpha \Psi_{\text{lm}}^\text{reg}(\mathbf{x}_\beta) \text{ with } \phi_{\text{lm}}^\alpha = i \sum_{\text{lm}} U_{\text{lm}}^{\alpha l'm'} Q_{\text{lm}}^\text{reg},
\]

and the integration in equation (3.6) leads, using equation (3.7), to the off-diagonal terms in equation (3.8).

\textbf{Diagonal terms}—The self-action, given by the second term of equation (3.6), is more interesting and more challenging. It can be expressed in terms of multipoles if we use the constraint for the currents, equations (3.3) and (3.4). To do so, we first note that in scattering theory one usually knows the incident solution and would like to find the outgoing scattered solution. We seek to relate a regular solution \( \Phi_\text{lm}(\mathbf{x}_\alpha) = \sum_{\text{lm}} \phi_{\text{lm}}^\alpha \Psi_{\text{lm}}^\text{reg}(\mathbf{x}_\alpha) \) and the outgoing scattered solution, \( \Phi_\text{lm}(\mathbf{x}_\beta) \), generated by the currents in the material—\( \text{a relation determined by the T-matrix, } \Phi_\text{lm} = (\Sigma^\alpha \Phi_\text{lm}) \) schematically \( i \Phi^\alpha = \Sigma^\alpha \Phi_\beta \) [34]. We face the inverse problem of determining \( \phi_{0,\text{lm}} \) for known scattering data \( Q_{\text{lm}}^\text{reg} \), hence,

\[
\phi_{0,\text{lm}} = i \sum_{l'm'} [T^\alpha_{l'm'}]^{-1} Q_{\text{lm}}^\text{reg},
\]

so that the incident field is given in terms of the \( S \)-matrix, as indicated in equation (3.4). Next, we express the self-action of the currents inside a body (the second term of equation (3.6)), as \( S^\alpha_{\text{reg}}[\mathbf{J}_\alpha] = \frac{1}{\mu} \int d\mathbf{x}_\alpha \{ \mathbf{E} \cdot \mathbf{D}^\alpha - \mathbf{B} \cdot \mathbf{H}^\alpha - (\mathbf{E}_\alpha \mathbf{D}_\beta^\alpha - \mathbf{B}_\alpha \mathbf{H}_\beta^\alpha) \} \), the change of the field action that results from placing the body into the \textit{fixed} (regular) incident field \( \mathbf{E}_0 = \mathbf{D}_0 \), \( \mathbf{H}_0 = \mathbf{B}_0 \), where \( \mathbf{E}, \mathbf{H} \) and \( \mathbf{D}, \mathbf{B} \) are the new total fields and fluxes in the presence of the body. Using \( \mathbf{D} = \epsilon_\alpha \mathbf{E}, \mathbf{H} = \mu_\alpha^{-1} \mathbf{B} \) inside the body and equation (3.3), straightforward manipulations lead to the simple self-action \( S^\alpha_{\text{reg}}[\mathbf{J}_\alpha] = -\frac{1}{\mu} \int d\mathbf{x}_\alpha \mathbf{J}_\alpha^\alpha \mathbf{E}_0([\mathbf{J}_\alpha, S^\beta]) \). If we substitute the regular wave expansion for \( \mathbf{E}_0 \) with coefficients of equation (3.9) and integrate by using equation (3.7), we get equation (3.8).

Having established the action for electric and magnetic multipoles, equation (3.7), the Casimir energy follows in complete analogy to the scalar case by integrating over the multipoles. Hence, the Casimir energy for two objects is again given by equation (2.40) with an additional factor of \( 1/2 \) since the electromagnetic field is real valued.

\textbf{4. Applications: scalar field}

In this section, we give a few typical applications of our method for a scalar field. We consider a \textit{real} scalar field fluctuating in the space between two spheres on which Robin boundary conditions, \( \phi - \lambda \partial_\mu \phi = 0 \), are imposed. Because a real field has half the oscillation modes
of a complex field, the Casimir energy in equation (2.40) must be divided by 2, giving
\[ \mathcal{E}_2[C] = \frac{hc}{2\pi} \int_0^\infty \text{d}k \ln \det(1 - T^\dagger\mathcal{U}T) \quad (4.1) \]

We allow for different Robin parameters \( \lambda_1, \lambda_2 \) at the spheres of radius \( R \). This choice allows us to study Dirichlet (\( \lambda/R \to 0 \)) and Neumann (\( \lambda/R \to \infty \)) boundary conditions on separate spheres as special cases. We obtain the Casimir energy as a series in \( R/d \) for large separations \( d \) and numerically at all separations. A comparison of the two approaches allows us to measure the rate of convergence of our results. We find that for Robin boundary conditions the sign of the force depends on the ratios \( \lambda_\alpha/R \) and on the separation \( d \).

### 4.1. Interaction of two spheres with Robin boundary conditions: general considerations

The Robin boundary condition \( \phi - \lambda_\alpha \partial_n \phi = 0 \) allows a continuous interpolation between Dirichlet and Neumann boundary conditions. Since the radius of the sphere introduces a natural length scale, it is convenient to replace \( \lambda \) by a dimensionless variable, \( \zeta_\alpha \equiv \lambda_\alpha/R \). For \( \zeta_\alpha > 0 \), the modulus of the field is suppressed if the surface is approached from the outside, while for \( \zeta_\alpha < 0 \) it is enhanced. Hence, for negative \( \zeta_\alpha \) bound surface states can be expected. All the information about the shape of the object and the boundary conditions at its surface is provided by the \( T \)-matrix. For spherically symmetric objects the \( T \)-matrix is diagonal and is completely specified by phase shifts \( \delta_l(k) \) that do not depend on \( m \),

\[ T_{\alpha m \alpha'}(k) = \delta_{lm} \frac{1}{\sqrt{\zeta}} (e^{2i\delta_l(k)} - 1) \quad (4.2) \]

In the discussion of the \( T \)-matrix for an individual object we again suppress the label \( \alpha \). The phase shifts for Robin boundary conditions are

\[ \cot \delta_l(k) = \frac{n_1(\xi) - \xi n_1'(\xi)}{j_1(\xi) - \xi j_1'(\xi)} \quad (4.3) \]

where \( \xi = kR \) and \( j_1(n_1) \) are spherical Bessel functions of first(second) kind. To apply equation (4.1), we have to evaluate the matrix elements of the transition matrices for imaginary frequencies \( k = i\xi \). Using \( j_1(i\xi) = i\sqrt{\pi/(2\xi)}I_{1+1/2}(\xi) \) and \( h_1^{(1)}(i\xi) = -i\sqrt{\pi/(2\xi)}K_{1+1/2}(\xi) \), we obtain for the \( T \)-matrix elements

\[ T_{\text{linm}}(i\xi) = (-1)^l \frac{\pi}{2} \left( \frac{1}{\xi} + 1/2 \right) \left( I_{1+1/2}(\xi) - zI_{1+1/2}'(\xi) \right) \sqrt{\pi/2} \left( K_{1+1/2}(\xi) - zK_{1+1/2}'(\xi) \right) \quad (4.4) \]

where \( z \equiv \kappa R \).

For two spherical objects we can assume that the center-to-center distance vector is parallel to the \( z \)-axis. Then the translation matrices simplify. For imaginary frequencies the translation matrix elements become

\[ U_{\text{linm}}(d) = \left( \begin{array}{c|c} 12 \\ \hline 21 \end{array} \right) (-1)^m i^{-l+l'} \sqrt{(2l+1)(2l'+1)} \times \sum_l \left( \begin{array}{cccc} l'' & l' & l'' & l' \\ 0 & 0 & 0 & 0 \end{array} \right) \left( \begin{array}{cc} l & -m \\ 0 & 0 \end{array} \right) \sqrt{\frac{2}{\pi \kappa d}} K_{l+l+1/2}(\kappa d) \quad (4.5) \]

where \( d \) is the separation distance.

An analysis of the \( T \)-matrix shows that it has poles for \(-1 < \zeta < 0\). For any \( \zeta \) in this interval, there exists a finite number of bound states, which increases as \( \xi \to 0 \). In the following, we restrict to \( \zeta \geq 0 \) and leave the study of interactions in the presence of bound states to a future publication.
The special case of spheres with Dirichlet boundary conditions has been studied in [23]. For two spheres of equal radius, the matrix \( \sum_{p} A_{ij}^{(m)} A_{ji}^{(m)} \) in the notation of [23] is proportional to our \( \mathbb{T}^{4} [12^{2}] \mathbb{T}^{1} \) times \( K_{s+1/2}(\kappa R) / K_{s+1/2}(\kappa R) \). It is easy to see that this proportionality factor drops out in the final result for the energy if one uses \( \ln \det = \text{tr} \ln \) in equation (4.1) and expands the logarithm around unity. Thus we agree with the results given in [23].

4.2. Asymptotic expansion for large separation

In this section, we consider the Casimir interaction between two spheres due to a scalar field obeying Robin boundary conditions, allowing for a different parameter \( \lambda_{1,2} \) on each sphere. The Casimir energy can be developed in an asymptotic expansion in \( R/d \) using \( \ln \det = \text{tr} \ln \) in equation (4.1). Expanding the logarithm in powers of \( N = \mathbb{T}^{4} [12^{2}] [2^{1}] \), since the \( \mathbb{T} \)-matrix has no poles in the region of interest we get

\[
E = -\frac{\hbar c}{2\pi} \int_{0}^{\infty} dx \sum_{p=1}^{\infty} \frac{1}{p} \text{tr}(N^{p}).
\]

We have performed the matrix operations using Mathematica. The scaling of the \( \mathbb{T} \)-matrix at small \( \kappa \) shows that the \( p \)th power of \( N \) (corresponding to \( 2p \) scatterings) becomes important at order \( d^{-(2p+1)} \). Partial waves of order \( l \) start to contribute at order \( d^{-(3l+2)} \) if the \( \mathbb{T} \)-matrix is diagonal in \( l \), which is the case for spherically symmetric objects. Hence the leading terms with \( p = 1 \) and \( l = 0 \) yield the exact energy to order \( d^{-4} \). In the following we will usually restrict the expansion to \( p \leq 3 \), \( l \leq 2 \), yielding the interaction to order \( d^{-8} \).

The large distance expansion of the Casimir energy can be written as

\[
E = \frac{\hbar c}{\pi d} \sum_{j=3}^{\infty} b_{j} \left( \frac{R}{d} \right)^{j-1},
\]

where the coefficients \( b_{j} \) of the term \( \sim d^{-j} \). These coefficients can be computed for general Robin boundary conditions [7]. Here we restrict to the limiting cases of Dirichlet and Neumann boundary conditions. An interesting property is that some coefficients \( b_{j} \) go to zero for \( \lambda_{a} \to \infty \), which corresponds to Neumann boundary conditions. If both \( \lambda_{a} \) go to infinity, the coefficients \( b_{j} \) vanish for \( j = 1, \ldots, 6 \), so that the leading term in the Casimir energy is \( \sim d^{-7} \) with a negative amplitude. Hence, Neumann boundary conditions lead to an attractive Casimir–Polder power law, as is known from electromagnetic field fluctuations. This result can be understood from the absence of low-frequency s-waves for Neumann boundary conditions. It is clearly reflected by the low-frequency expansion of the \( \mathbb{T} \)-matrix, which has a vanishing amplitude for \( \lambda_{a} \to \infty \) if \( l = 0 \). If one \( \lambda_{a} = 0 \) and the other goes to infinity, only the coefficients \( b_{3} \) and \( b_{5} \) vanish so that the energy scales as \( d^{-5} \) with a positive amplitude. In general, one has \( b_{3} < 0 \) for \( \lambda_{a} > 0 \), so that at asymptotic distances the Casimir force is attractive for all non-negative finite \( \lambda_{a} \), and for \( \lambda_{a} \) both infinite. It is repulsive if one \( \lambda_{a} \) is finite and the other infinite, i.e., if one sphere obeys Neumann boundary conditions. However, at smaller distances the interaction can change sign depending on \( \lambda_{a} \), as shown below.

More precisely, we obtain the following results. If both \( \lambda_{a} = 0 \), the field obeys Dirichlet conditions at the two spheres and the first six coefficients are

\[
\begin{align*}
&b_{3} = -\frac{1}{4}, &b_{4} = -\frac{1}{4}, &b_{5} = -\frac{77}{38}, \\
&b_{6} = -\frac{25}{16}, &b_{7} = -\frac{29837}{2880}, &b_{8} = -\frac{64911752}{17552}.
\end{align*}
\]

If Neumann conditions are imposed on both surfaces, the coefficients are

\[
\begin{align*}
&b_{3} = 0, &b_{4} = 0, &b_{5} = 0, &b_{6} = 0, \\
&b_{7} = -\frac{161}{96}, &b_{8} = 0, &b_{9} = -\frac{3011}{192}, &b_{10} = -\frac{175}{172}.
\end{align*}
\]
clearly showing that the asymptotic interaction has a Casimir–Polder power law ∼\( \mathcal{O}(d^{-7}) \). Also, as in the electromagnetic case, the next to leading order \( \mathcal{O}(d^{-8}) \) vanishes [6]. Therefore we have included the two next terms of the series. For mixed Dirichlet/Neumann boundary conditions, we obtain

\[
\begin{align*}
&b_3 = 0, & b_4 = 0, & b_5 = \frac{17}{28}, & b_6 = \frac{11}{52}, & b_7 = \frac{663}{1720}, & b_8 = \frac{235}{1720}.
\end{align*}
\]

(4.10)

It is important to note that the series in equation (4.7) is an asymptotic series and therefore cannot be used to obtain the interaction at short distances.

4.3. Numerical results for Robin boundary conditions on two spheres at all separations

The primary application of our analysis is to compute the Casimir energy and force to high accuracy over a broad range of distances. However, to obtain the interaction at all distances, equation (4.1) has to be evaluated numerically. We shall see that the domain where our method is least accurate is when the two surfaces approach one another. That is the regime where semiclassical methods like the proximity force approximation (PFA) become exact. Because of its role in this limit, and because it is often used (with little justification) over wide ranges of separations, it is important to compare our calculations with the PFA predictions.

In the proximity force approximation, the energy is obtained as an integral over infinitesimal parallel surface elements at their local distance \( L \), measured perpendicular to a surface \( \Sigma \) that can be one of the two surfaces of the objects, or an auxiliary surface placed between the objects. The PFA approximation for the energy is then given by

\[
\mathcal{E}_{\text{PFA}} = \frac{1}{A} \int_{\Sigma} \mathcal{E}_1(L) \, dS,
\]

(4.11)

where \( \mathcal{E}_1(L)/A \) is the energy per area for two parallel plates with distance \( L \). The Casimir energy for parallel plates with Robin boundary conditions has been obtained as function of \( \lambda \alpha/L \) in [7]. The behavior of the PFA at asymptotically small or large \( \lambda \alpha/L \) determines the Casimir interaction as \( L \to 0 \). For all nonzero values of \( \lambda_1, \lambda_2 \), we take \( \lambda \alpha/L \to \infty \), but for the Dirichlet case, \( \lambda = 0 \), the limit \( \lambda \alpha/L \to 0 \) applies. For parallel plates with Robin boundary conditions, in the limit \( \lambda_1, \lambda_2/L \gg 1 \) we obtain the result for Neumann boundary conditions on both plates,

\[
\Phi(\lambda_1/L, \lambda_2/L) \to \Phi_0^- = -\frac{\pi^2}{1440},
\]

(4.12)

and for \( \lambda_1, \lambda_2/L \ll 1 \) we obtain the identical result for plates with Dirichlet conditions. Finally for \( \lambda_1, \lambda_2/L \ll 1 \ll \lambda_2, \lambda_1/L \), we obtain the parallel plate result for unlike (Dirichlet/Neumann) boundary conditions,

\[
\Phi(\lambda_1/L, \lambda_2/L) \to \Phi_0^+ = -\frac{7}{8} \Phi_0^- = \frac{7\pi^2}{11520}.
\]

(4.13)

The last case is relevant at short distances if one of the \( \lambda \alpha = 0 \). For two spheres of radius \( R \) and center-to-center separation \( d \) with Robin boundary conditions, the PFA results can now be obtained easily from equation (4.11). In terms of the surface-to-surface distance \( L = d - 2R \), we get

\[
\mathcal{E}_{\text{PFA}} = \Phi_0^\pm \frac{\pi}{2} \frac{R \hbar c}{(d - 2R)^2},
\]

(4.14)

where + applies if one and only one \( \lambda \alpha = 0 \), and − in all other cases. Hence, at small separation the interaction becomes independent of \( \lambda \alpha \), in the sense that it only depends on whether one \( \lambda \alpha \) is zero.
Table 1. The sign of the Casimir force between two plates and two spheres with Robin boundary conditions at asymptotically small and large surface-to-surface distance $L$. The sign in these two limits is identical for plates and spheres. Here ‘$-$’ and ‘$+$’ indicate attractive and repulsive forces, respectively.

| $\lambda_1$ | $\lambda_2$ | $L \to 0$ | $L \to \infty$ | Remark |
|------------|------------|-----------|----------------|--------|
| 0          | 0          | $-$       | $-$            | $-$ for all $L$ |
| $\infty$   | 0          | $+$       | $+$            | $+$ for all $L$ |
| $\infty$   | $\infty$  | $-$       | $-$            | $-$ for all $L$ |
| $]0, \infty[$ | $]0, \infty[$ | $-$       | $-$            | $+$ at intermediate $L$ for large enough ratio of $\lambda_1$, $\lambda_2$, (for plates $\lambda_1/\lambda_2$ or $\lambda_2/\lambda_1 \gtrsim 2.8$) |
| $]0, \infty[$ | 0          | $+$       | $-$            | |
| $]0, \infty[$ | $\infty$  | $-$       | $+$            | |

With the results obtained above, we can analyze the sign of the interaction between plates and spheres at both asymptotically large and small distances. Since the PFA result is expected to hold in the limit where the distance tends to zero, equation (4.14) predicts the sign of the interaction between spheres in the limit of vanishing distance. In the limit of large distances, we can compare the results for parallel planes from equations (4.12) and (4.13) to our calculations for two spheres. We find that the sign of the asymptotic interaction depends on the choice for $\lambda_\alpha$ and is identical for plates and spheres. Hence, we obtain a complete characterization of the sign of the interaction at asymptotically large and small distances for the plate and sphere geometry, which is summarized in table 1. However, as we have seen above, the power-law decay at large distance is quite different for plates and spheres.

4.3.1. Casimir forces for all separations. To go beyond the analytic large distance expansion, we compute numerically the interaction between two spheres of the same radius $R$ with Robin boundary conditions. Guided by the classification of the Casimir force according to its sign at small, intermediate and large separations, we discuss the six different cases listed in table 1. Our numerical approach starts from equation (4.1). Using the matrix elements of equations (4.4) and (4.5), we compute the determinant and the integral over imaginary frequency numerically. We truncate the matrices at a finite multipole order $l$ so that they have dimension $(1+l)^2 \times (1+l)^2$, yielding a series of estimates $E^{(l)}$ for the Casimir energy.

$E^{(1)}$ gives the exact result for asymptotically large separations, while for decreasing separations an increasing number of multipoles has to be included. The exact Casimir energy at all separations is obtained by extrapolating the series $[E^{(l)}]$ to $l \to \infty$. We observe an exponentially fast convergence as $|E^{(l)} - E| \sim e^{-\delta l (d/R-2)}$, where $\delta$ is a constant of order unity. Hence, as the surfaces approach each other for $d \to 2R$, the rate of convergence tends to zero. However, we find that the first $l = 20$ elements of the series are sufficient to obtain accurate results for the energy at a separation with $R/d = 0.48$, corresponding to a surface-to-surface distance of the spheres of $L = 0.083R$, i.e., approximately 4% of the sphere diameter. In principle, our approach can be extended to even smaller separations by including higher order multipoles. However, at such small separations semiclassical approximations like the PFA start to become accurate and can be also used.

The results for Dirichlet and Neumann boundary conditions are shown in figure 1. All energies are divided by $E_{\text{PFA}}$, given in equation (4.14), with the corresponding amplitude $\Phi_\alpha^\phi$ (repulsive at small separations) or $\Phi_\alpha^\psi$ (attractive at small separations). For like boundary conditions, either Dirichlet or Neumann, the interaction is attractive at all separations, but for
 Unlike boundary conditions it is repulsive. At large separations the numerical results show excellent agreement with the asymptotic expansion derived above. Note that the reduction of the energy compared to the PFA estimate at large distances depends strongly on the boundary conditions, showing the different power laws at asymptotically large separations. In the limit of a vanishing surface-to-surface distance \((R/d \to 1/2)\), the energy approaches the PFA estimate in all cases. Generically, the PFA overestimates the energy: \(E_{\text{PFA}}\) is approached from below for \(R/d \to 1/2\), except in the case of Dirichlet boundary conditions on both spheres, where the PFA underestimates the actual energy in a range of \(0.3 \lesssim R/d < 1/2\). The deviations from the PFA are most pronounced for Neumann boundary conditions. At a surface-to-surface distance of \(L = 3R\ (R/d = 0.2)\), the PFA overestimates the energy by a factor of 100.
Casimir interactions for Robin boundary conditions with finite $\lambda_\alpha$ are shown in figure 2. If $\lambda_1 = \lambda_2$ the interaction is always attractive. If $\lambda_\alpha$ are not equal and their ratio is sufficiently large, the Casimir force changes sign either once or twice. This behavior resembles the interaction of two plates with Robin boundary conditions. However, the criterion for the existence of sign changes in the force now depends not only on $\lambda_1/\lambda_2$, but on both quantities $\lambda_1/R$ and $\lambda_2/R$ separately. Even with $\lambda_1/\lambda_2$ fixed, for smaller $\lambda_\alpha/R$ there can be sign changes in the force, while for larger $\lambda_\alpha/R$ the force is attractive at all distances. When the ratio $\lambda_1/\lambda_2$ is sufficiently large (or formally infinite for Dirichlet or Neumann boundary conditions), we...
can identify three different generic cases where sign changes in the force occur:

- First, we consider Dirichlet boundary conditions ($\lambda_1 = 0$) on one sphere and a finite non-vanishing $\lambda_2/R$ at the other sphere. Figure 2(a) displays the energy for $\lambda_2/R = 10$ as a typical example. At large distances the energy is negative, while it is positive at short separations with one sign change in between. The asymptotic expansion of equation (4.7) yields the exact energy at separations well below the sign change [7]. While the expansion predicts qualitatively the correct overall behavior of the energy, it does not yield the actual position of the sign change correctly. Of course, for the Casimir interaction between compact objects, the sign of the force $F = -\partial E/\partial d$ is the physically important quantity, not the energy. The distance at which the force vanishes cannot be deduced directly from the slope of the curve for $\hat{E} = E/E_{PFA}$, since one has

$$\hat{E}'(d) = \frac{1}{E_{PFA}(d)} \left[ E'(d) + \frac{2}{d - 2R} E(d) \right]. \quad (4.15)$$

The force vanishes at the distance $d_0$ if $E'(d_0) = 0$, so that

$$\hat{E}'(d_0) = \frac{2}{d_0 - 2R} \hat{E}(d_0). \quad (4.16)$$

Hence the distance at which the force vanishes is determined by the position $d_0$ where the curve of the auxiliary function $t(d) = \tau(d/R - 2)^2$ is tangent to the curve of $\hat{E}$. The two unknown quantities $d_0$ and $\tau$ are then determined by the conditions $\hat{E}(d_0) = t(d_0)$ and $\hat{E}'(d_0) = t'(d_0)$. This procedure allows us to obtain the distance at which the force vanishes easily, without computing derivatives numerically. The tangent segment of the curve for $t(d)$ is shown in figure 2(a) as a dotted line. From this construction we find that at a distance $d_{\rightarrow R}$ the force changes from attractive to repulsive for decreasing separations. The position $d_{\rightarrow R}$ corresponds to a minimum of the energy and decreases with decreasing $\lambda_2/R$, so that in the limit $\lambda_2/R \rightarrow 0$ it approaches the case of two spheres with Dirichlet boundary conditions, where the force is always attractive.

- Second, we study Neumann boundary conditions on one sphere and a finite non-vanishing $\lambda_2/R$ at the other sphere. As an example we choose again $\lambda_2/R = 10$, as shown in figure 2(b). The energy is positive at large distances and becomes negative at small distances. The asymptotic expansion is found to be valid well below the separation where the sign of the energy changes [7]. Hence, the expansion describes the behavior of the energy qualitatively, but does not predict the precise position of the sign change. The sign change of the force can be obtained by the method described above. At a position $d_{\rightarrow R}$, the force changes from repulsive to attractive with decreasing separation and the energy is maximal. A decreasing (increasing) $\lambda_2/R$ shifts $d_{\rightarrow R}$ to smaller (larger) separations. This result is consistent with an entirely repulsive (attractive) force for Neumann–Dirichlet (Neumann–Neumann) boundary conditions.

- The third case is obtained if both $\lambda_1$ are finite and nonzero. A typical example with $\lambda_1/R = 20$ and $\lambda_2/R = 1$ is shown in figure 2(c). The energy is negative both at large and small separations but turns positive at intermediate distances. The asymptotic expansion applies again at sufficiently large separations beyond the position where the energy becomes positive. For values of the ratio $\lambda_1/\lambda_2$ that are larger than an $R$-dependent threshold, the force changes sign twice, so that it is repulsive between the separations $d_{\rightarrow R}$ and $d_{\rightarrow R}$. The energy has a minimum (maximum) at $d_{\rightarrow R}$ ($d_{\rightarrow R}$). If $\lambda_1/R$ increases and $\lambda_2/R$ decreases, the repulsive region grows until eventually the force becomes repulsive at all separations, corresponding to the limit of Dirichlet/Neumann boundary conditions. Decreasing $\lambda_1/R$ and increasing $\lambda_2/R$ reduces the interval with repulsion. In this case,
where the first ten coefficients are
\[ c_n = -\frac{\eta K_{l+1}(-z)}{2} n I_{l+1/2}(n z) - n I_{l+1/2}(n z) [I_{l+1/2}(z) + 2z I_{l+1/2}''(z)]. \]

where \( E \) are Bessel functions.

Due to symmetry, the multipoles are decoupled so that the T-matrix is diagonal,
\[ T_{lmlm}^{11} = (-1)^{l} \frac{\eta I_{l+1/2}(-z)}{2} n I_{l+1/2}(n z) - n I_{l+1/2}(n z) [I_{l+1/2}(z) + 2z I_{l+1/2}''(z)]. \]

where \( R, z = \kappa R, n = \sqrt{\epsilon(\kappa \mu(\kappa))}, \eta = \sqrt{\epsilon(\kappa \mu(\kappa))} \) and \( I_{l+1/2}, K_{l+1} \) are Bessel functions. \( T_{lmlm}^{22} \) is obtained from equation (5.1) by interchanging \( \epsilon \) and \( \mu \). For all partial waves, the leading low-frequency contribution is determined by the static electric multipole polarizability, \( \alpha^{E} = \frac{1}{\sqrt{\epsilon(\kappa \mu(\kappa))}} \) and the corresponding magnetic polarizability, \( \alpha^{M} = \frac{1}{\sqrt{\kappa \mu(\kappa)}} \). Including the next to leading terms, the T-matrix has the structure
\[ T_{lmlm}^{11} = \kappa^{2} \left[ (\frac{1}{2l+1})^{1/2} [1 + \gamma_{M}^{E}] \kappa^{2} + \gamma_{M}^{E} \kappa^{4} + \ldots \right], \]

and \( T_{lmlm}^{22} \) is obtained by interchanging \( \alpha^{E} \) and \( \alpha^{M} \). The first terms are \( \gamma_{M}^{E} = -\frac{4}{\mu} + \frac{\mu}{\mu - 6} \) and \( \gamma_{E}^{M} = \frac{4}{9}(4/\mu - 1)/(\mu + 2)^2 \). Matrix operations are performed with Mathematica, and we find the interaction
\[ E = -\frac{hc}{\pi} \left\{ \frac{23}{4} \left[ (\alpha_{1}^{E})^2 + (\alpha_{1}^{M})^2 \right] - \frac{7}{2} \alpha_{1}^{E} \alpha_{1}^{M} \right\} \frac{1}{d^3} \]
\[ + \frac{9}{16} \left[ \alpha_{1}^{E} (59 \alpha_{2}^{E} - 11 \alpha_{2}^{M} + 86 \gamma_{13}^{E} - 54 \gamma_{13}^{M}) + E \leftrightarrow M \right] \frac{1}{d^3} \]
\[ + \frac{315}{16} \left[ \alpha_{1}^{E} (7 \gamma_{14}^{E} - 5 \gamma_{14}^{M}) + E \leftrightarrow M \right] \frac{1}{d^{10}} + \ldots \],

where \( E \leftrightarrow M \) indicates terms with exchanged superscripts. The leading term, \( \sim d^{-7} \), has precisely the form of the Casimir–Polder force between two atoms [8], including magnetic effects [9]. The higher order terms are new, and provide the first systematic result for dielectrics with strong curvature. There is no \( \sim 1/d^9 \) term.

The limit of perfect metals follows for \( \epsilon \to \infty, \mu \to 0. \) Then higher orders are easily included, yielding an asymptotic series
\[ E = -\frac{hc}{\pi} \frac{R^6}{d^3} \sum_{n=0}^{N} c_n \left( \frac{R}{d} \right)^n, \]

where the first ten coefficients are \( c_0 = 143/16, c_1 = 0, c_2 = 7947/160, c_3 = 2065/32, c_4 = 27705/100800, c_5 = -55251/64, c_6 = 137321255041/144506880, c_7 = -7583389/320, c_8 = -2516749/144274023/44508119040, c_9 = 24795358965739/275251200. \) This series is obtained by expanding in powers of \( \mathbb{N} \) and frequency \( \kappa, \) and does
not converge for any fixed $R/d$. To obtain the energy at all separations, one has to compute equation (2.40) without these expansions. This is done as before in the case of a scalar field: we truncate the matrix $N$ at a finite multipole order $l$, and compute the determinant and the integral numerically. The result is shown in figure 3 for perfect metal spheres. Our data indicate again that the energy converges as $e^{-\lambda(d/R - 2\delta)}$ to its exact value at $l \to \infty$, with $\delta \sim O(1)$. Our result spans all separations between the Casimir–Polder limit for $d \gg R$, and the proximity force approximation (PFA) for $R/d \to 1/2$. At a surface-to-surface distance $L = 4R/3$ ($R/d = 0.3$), PFA overestimates the energy by a factor of 10. Including up to $l = 32$ and extrapolating based on the exponential fit, we can accurately determine the Casimir energy down to $R/d = 0.49$, i.e. $L = 0.04R$. A similar numerical evaluation can be also applied to dielectrics [7].
