Legendrian and transverse twist knots

Received December 1, 2010 and in revised form September 14, 2011

Abstract. In 1997, Chekanov gave the first example of a Legendrian nonsimple knot type: the $m(5_2)$ knot. Epstein, Fuchs, and Meyer extended his result by showing that there are at least $n$ different Legendrian representatives with maximal Thurston–Bennequin number of the twist knot $K_{-2n}$ with crossing number $2n + 1$. In this paper we give a complete classification of Legendrian and transverse representatives of twist knots. In particular, we show that $K_{-2n}$ has exactly $\lceil n^2/2 \rceil$ Legendrian representatives with maximal Thurston–Bennequin number, and $\lceil n/2 \rceil$ transverse representatives with maximal self-linking number. Our techniques include convex surface theory, Legendrian ruling invariants, and Heegaard Floer homology.

Keywords. Legendrian knot, transverse knot, twist knots

1. Introduction

Throughout this paper, we consider Legendrian and transverse knots in $\mathbb{R}^3$ with the standard contact structure $\xi_{std} = \ker (dz - y dx)$.

A twist knot is a twisted Whitehead double of the unknot, specifically, any knot $K = K_m$ of the type shown in Figure 1. Twist knots have long been an important class of knots to consider, particularly in contact geometry. If Legendrian knots in a given topological knot type are determined up to Legendrian isotopy by their classical invariants, namely their Thurston–Bennequin and rotation numbers, then the knot type is said to be Legendrian simple; otherwise it is Legendrian nonsimple. While there is no reason to believe all knot types should be Legendrian simple, it has historically been difficult to prove otherwise. Chekanov [C] and, independently, Eliashberg [El2] developed invariants of Legendrian knots that show that $K_{-4} = m(5_2)$ has Legendrian representa-
Fig. 1. The twist knot $K_m$; the box contains $m$ right-handed half-twists if $m \geq 0$, and $|m|$ left-handed half-twists if $m < 0$.

Twists that are not determined by their classical invariants, providing the first example of a Legendrian nonsimple knot. Shortly thereafter, Epstein, Fuchs, and Meyer [EFM] generalized the result of Chekanov and Eliashberg to show that $K_m$ is Legendrian nonsimple for all $m \leq -4$, and in fact that these knot types contain an arbitrarily large number of Legendrian knots with the same classical invariants. Again these were the first such examples.

One can also ask if a knot is transversely simple, that is, are transverse knots in that knot type determined by their self-linking number? It is more difficult to prove transverse nonsimplicity than Legendrian nonsimplicity. In particular, there are knot types that are Legendrian nonsimple but transversely simple [EH2], whereas any transversely nonsimple knot must be Legendrian nonsimple as well. The first examples of transversely nonsimple knots were produced in 2005–6 by Birman and Menasco [BM], and Etnyre and Honda [EH3]. It has long been suspected that some twist knots are transversely nonsimple, and this was proven very recently by Ozsváth and Stipsicz [OS] using the transverse invariant in Heegaard Floer homology from [LOSS].

Although twist knots have long supplied a useful test case for new Legendrian invariants, such as contact homology and Legendrian Heegaard Floer invariants (cf. the work of Epstein–Fuchs–Meyer and Ozsváth–Stipsicz above), a complete classification of Legendrian and transverse twist knots has been elusive. In this paper, we establish this classification and in particular identify which twist knots are Legendrian and transversely nonsimple. As a byproduct, we obtain a complete classification of an infinite family of transversely nonsimple knot types. This is one of the first (Legendrian or transversely) nonsimple families where a classification is known; see also [ELT].

Theorem 1.1 (Classification of Legendrian twist knots). Let $K = K_m$ be the twist knot of Figure 1, with $m$ half-twists. We discard the case $m = -1$, which is the unknot.

1. For $m \geq -2$ even, there is a unique representative of $K_m$ with maximal Thurston–Bennequin number, $tb = -m - 1$. This representative has rotation number $rot = 0$, and all other Legendrian knots of type $K_m$ destabilize to the one with maximal Thurston–Bennequin number.

2. For $m \geq 1$ odd, there are exactly two representatives with maximal Thurston–Bennequin number, $tb = -m - 5$. These representatives are distinguished by their rotation numbers, $rot = \pm 1$, and a negative stabilization of the $rot = 1$ knot is isotopic to a
positive stabilization of the rot $= -1$ knot. All other Legendrian knots destabilize to at least one of these two.

(3) For $m \leq -3$ odd, $K_m$ has $-(m+1)/2$ Legendrian representatives with $(tb, \text{rot}) = (-3, 0)$. All other Legendrian knots destabilize to one of these. After any positive number of stabilizations (with a fixed number of positive and negative stabilizations), these $-(m+1)/2$ representatives all become isotopic.

(4) For $m \leq -2$ even with $m = -2n$, $K_m$ has $\lceil n^2/2 \rceil$ different Legendrian representations with $(tb, \text{rot}) = (1, 0)$. All other Legendrian knots destabilize to one of these. These Legendrian knots fall into $\lfloor n/2 \rfloor$ different Legendrian isotopy classes after any given positive number of positive stabilizations, and $\lceil n/2 \rceil$ different Legendrian isotopy classes after any given positive number of negative stabilizations. After at least one positive and one negative stabilization (with a fixed number of each), the knots all become Legendrian isotopic.

In particular, $K_m$ is Legendrian simple if and only if $m \geq -3$.

The content of Theorem 1.1 is depicted in the Legendrian mountain ranges in Figures 2–4. The Legendrian representatives of $K_m$ with maximal Thurston–Bennequin number will be given in Section 3. Note that the cases $-3 \leq m \leq 2$ in Theorem 1.1 were already known by the classification of Legendrian unknots by Eliashberg and Fraser [EF] and Legendrian torus knots and the figure eight knot by Etnyre and Honda [EH1].

Fig. 2. Schematic Legendrian mountain range for $K_{2n}$ ($n \geq -1$) (left) and $K_{2n-1}$ ($n \geq 1$) (right). Rotation number is plotted in the horizontal direction, Thurston–Bennequin number in the vertical direction. The numbers represent the number of Legendrian representatives for a particular $(tb, \text{rot})$ (here, all numbers are 1 since these knot types are Legendrian simple), and the signed arrows represent positive and negative stabilization.

Fig. 3. Legendrian mountain range for $K_{-2n-1}$ ($n \geq 1$).
Theorem 1.2 (Classification of transverse twist knots). Let \( K = K_m \) be the twist knot of Figure 1, with \( m \) half-twists.

1. If \( m \) is even and \( m \geq -2 \) or \( m \) is odd, then \( K_m \) is transversely simple. Moreover, the transverse representative of \( K_m \) with maximal self-linking number has \( \text{sl} = -m - 1 \) if \( m \geq -2 \) is even, \( \text{sl} = -m - 4 \) if \( m > -1 \) is odd, \( \text{sl} = -1 \) if \( m = -1 \), and \( \text{sl} = -3 \) if \( m < -1 \) is odd.

2. If \( m \leq -4 \) is even with \( m = -2n \), then \( K_m \) is transversely nonsimple. There are \( \lceil n/2 \rceil \) distinct transverse representatives of \( K_m \) with maximal self-linking number \( \text{sl} = 1 \). Any two of these become transversely isotopic after a single stabilization, and all other transverse representatives of \( K_m \) destabilize to one of these.

We prove these classification theorems by using convex surface techniques, along the lines of the recipe described in [EH1], to produce an exhaustive list of all nondestabilizable Legendrian twist knots. This is the most technically difficult part of the proof and is deferred until Section 4. Given this list, we use the Legendrian ruling invariants of Pushkar’–Chekanov and Fuchs, along with the aforementioned result of Ozsváth–Stipsicz, to distinguish nonisotopic classes of Legendrian and transverse twist knots; this is done in Section 3. We begin with a review of some necessary background in Section 2.

2. Background and preliminary results

In this section we recall some basic facts about convex surfaces and bypasses, as well as ruling invariants of Legendrian knots.

2.1. Convex surfaces and bypasses

Convex surfaces are the primary tool we will use in this paper. We assume the reader is familiar with this theory at the level found in [EH1, G, H]. For the convenience of the reader and to clarify various orientation issues we will briefly recall some of the facts...
about convex surfaces most germane to the proofs below, but for the basic definitions and results the reader is referred to the above references.

Recall that if \( \Sigma \) is a convex surface and \( \alpha \) a Legendrian arc in \( \Sigma \) that intersects the dividing curves \( \Gamma_{\Sigma} \) in three points \( p_1, p_2, p_3 \) (where \( p_1, p_3 \) are the endpoints of the arc), then a bypass for \( \Sigma \) (along \( \alpha \)) is a convex disk \( D \) with Legendrian boundary such that

- \( D \cap \Sigma = \alpha \),
- \( \text{tb}(\partial D) = -1 \),
- \( \partial D = \alpha \cup \beta \),
- \( \alpha \cap \beta = \{p_1, p_3\} \) are corners of \( D \) and elliptic singularities of \( D_\xi \).

The most basic property of bypasses is how a convex surface changes when pushed across a bypass.

**Theorem 2.1** (Honda [H]). Let \( \Sigma \) be a convex surface and \( D \) a bypass for \( \Sigma \) along \( \alpha \subset \Sigma \). Inside any open neighborhood of \( \Sigma \cup D \) there is a (one-sided) neighborhood \( N = \Sigma \times [0, 1] \) of \( \Sigma \cup D \) with \( \Sigma = \Sigma \times \{0\} \) (if \( \Sigma \) is oriented, orient \( N \) so that \( \Sigma = -\Sigma \times \{0\} \) as oriented manifolds) such that \( \Gamma_{\Sigma} \) is related to \( \Gamma_{\Sigma \times \{1\}} \) as shown in Figure 5.

![Fig. 5. Result of a bypass attachment: original surface \( \Sigma \) with attaching arc \( \alpha \) (left); the surface \( \Sigma' = \Sigma \times \{1\} \) (right). The dividing curves \( \Gamma_\Sigma \) and \( \Gamma_{\Sigma'} \) are shown as thicker curves.](image)

In the above discussion the bypass is said to be attached from the front. To attach a bypass from the back one needs to change the orientation of the interval \([0, 1]\) in the above theorem and mirror Figure 5.

If \( \Sigma \) and \( \Sigma' \) are two convex surfaces, \( \partial \Sigma' \) is a Legendrian curve contained in \( \Sigma \), and \( \Sigma \cap \Sigma' = \partial \Sigma' \), then if \( \Sigma' \) has a boundary-parallel dividing curve (and there are other dividing curves on \( \Sigma' \)) then one can always find a bypass for \( \Sigma \) contained in \( \Sigma' \) (and containing the boundary-parallel dividing curve). This is a simple application of the Legendrian realization principle [K]. It is useful to be able to find bypasses in other ways too. For this we have the notion of bypass rotation.

**Lemma 2.2** (Honda, Kazez, and Matić [HKM]). Suppose \( \Sigma \) is a convex surface containing a disk \( D \) such that \( D \cap \Gamma_\Sigma \) is as shown in Figure 6. Also suppose \( \delta \) and \( \delta' \) are as shown in the figure. If there is a bypass for \( \Sigma \) attached along \( \delta \) from the front side of the diagram, then there is a bypass for \( \Sigma \) attached along \( \delta' \) from the front.

We end our brief review of convex surfaces by describing how two convex surfaces that come together along a Legendrian circle in their boundary can be made into a single convex surface by rounding their corners.
Lemma 2.3 (Honda [H]). Suppose that $\Sigma$ and $\Sigma'$ are convex surfaces with dividing curves $\Gamma$ and $\Gamma'$ respectively, and $\partial \Sigma' = \partial \Sigma$ is Legendrian. Model $\Sigma$ and $\Sigma'$ in $\mathbb{R}^3$ by $\Sigma = \{(x, y, z) : x = 0, y \geq 0\}$ and $\Sigma' = \{(x, y, z) : y = 0, x \geq 0\}$. Then we may form a surface $\Sigma''$ from $S = \Sigma \cup \Sigma'$ by replacing $S$ in a small neighborhood $N$ of $\partial \Sigma$ (thought of as the $z$-axis) with the intersection of $N$ with $\{(x, y, z) : (x - \delta)^2 + (y - \delta)^2 = \delta^2\}$. For a suitably chosen $\delta$, $\Sigma''$ will be a smooth surface (actually just $C^1$, but it can then be smoothed by a $C^1$ small isotopy which can easily be seen not to change the characteristic foliation) with dividing curve as shown in Figure 7.

In this lemma, rounding a corner between two convex surfaces causes the dividing curves on the two surfaces to connect up as follows: moving from $\Sigma$ to $\Sigma'$, the dividing curves move up (resp. down) if $\Sigma'$ is to the right (resp. left) of $\Sigma$.

2.2. Ruling invariants

In order to distinguish between Legendrian isotopy classes of twist knots in Section 3, we use invariants of Legendrian knots in standard contact $\mathbb{R}^3$ known as the $\mu$-graded ruling invariants, as introduced by Pushkar’–Chekanov [PC] and Fuchs [F]. Here we very briefly recall the relevant definitions and results; for further details, see, e.g., the above papers or [Et].

Given the front $(xz)$ projection of a Legendrian knot in $\mathbb{R}^3$, a ruling is a one-to-one correspondence between left and right cusps, along with a decomposition of the front as a union of pairs of paths beginning at a left cusp and ending at the corresponding right cusp, satisfying the following conditions:

- all paths are smooth except possibly at double points (crossings) in the front, and never change direction with respect to $x$-coordinate.
- the two paths for a particular pair of cusps do not intersect except at the two cusp endpoints;
- any two arbitrary paths intersect at most at cusps and crossings;
- at a crossing where two paths (which must necessarily have different endpoints) intersect and one lies entirely above the other (such a crossing is a switch), the two paths and their companion paths must be arranged locally as in Figure 8.

![Fig. 8. Allowed and disallowed switches in a ruling. In each diagram, the two solid arcs are paired together (i.e., share cusp endpoints), as are the two dashed arcs. Other pairs of arcs, which may be present, are not shown.](image)

See Figure 9 for examples of rulings; note that a ruling is uniquely determined by its switches, and can be thought of as a “partial 0-resolution” of the front.

![Fig. 9. Rulings of Legendrian versions of the twist knots $K_{–4}$, $K_3$, and $K_4$. Dots indicate switches.](image)

One can refine the concept of a ruling by considering Maslov degrees. Removing the $2c$ left and right cusps from a front (not necessarily with a ruling) yields $2c$ arcs, each connecting a left cusp to a right cusp. If $\text{rot}$ is the rotation number of the front, then we can assign integers (Maslov numbers) mod $2\text{rot}$ to each of these arcs so that at each cusp, the upper arc (with higher $z$ coordinate) has Maslov number 1 greater than the lower arc; for a connected front, these numbers are well-defined up to adding a constant to all arcs. To each crossing in the front, we can define the Maslov degree to be the Maslov number of the strand with more negative slope minus the Maslov number of the strand with more positive slope. Finally, if $\rho$ is any integer dividing $2\text{rot}$, then we say that a ruling of the front is $\rho$-graded if all switches have Maslov degree divisible by $\rho$. In particular, a 1-graded ruling (also known as an ungraded ruling) is a ruling with no condition on the switches.

**Proposition 2.4** (Pushkar’ and Chekanov [PC]). Let $K$ be a Legendrian knot with rotation number $\text{rot}(K)$. For any $\rho$ dividing $2\text{rot}(K)$, the number of $\rho$-graded rulings of the front of $K$ is an invariant of the Legendrian isotopy class of $K$. 
The existence of rulings is closely related to the maximal Thurston–Bennequin number of a knot.

**Proposition 2.5** (Rutherford [R]). *If a Legendrian knot $K$ admits an ungraded ruling, then it maximizes Thurston–Bennequin number within its topological class.*

For twist knots, Proposition 2.5 allows easy calculation of the maximal value of $tb$; we note that the following result can also be derived from the more general calculation for two-bridge knots from [N].

**Proposition 2.6.** The maximal Thurston–Bennequin number for $K_m$ is

$$
\overline{tb}(K_m) = \begin{cases} 
-m - 1, & m \geq 0 \text{ even}, \\
-m - 5, & m \geq 1 \text{ odd}, \\
-1, & m = -1, \\
1, & m \leq -2 \text{ even}, \\
-3, & m \leq -3 \text{ odd}.
\end{cases}
$$

**Proof.** Figure 9 shows ungraded rulings for Legendrian forms of $K_{-4}$, $K_3$, and $K_4$; these have obvious generalizations to Legendrian knots of type $K_m$ for $m \leq -2$, $m \geq 1$ odd, and $m \geq 0$ even, respectively, each of which has an ungraded ruling. It follows from Proposition 2.5 that each of these knots maximizes $tb$. Easy calculations of Thurston–Bennequin numbers for each case (along with the fact that $K_{-1}$ is the unknot) yield the proposition. \(\square\)

### 3. The classification of Legendrian twist knots

In this section we will classify Legendrian and transverse twist knots by proving Theorems 1.1 and 1.2. We begin with several preliminary results that will be proved in Section 4.

**Theorem 3.1.** *For $m \leq -2$, any Legendrian representative of $K = K_m$ with maximal $tb$ is Legendrian isotopic to some Legendrian knot whose front projection is of the form depicted in Figure 10, where the rectangle contains $|m + 2|$ negative half-twists each of which is of type $Z$ or $S$.

![Fig. 10. A front projection for $K_m$ for $m \leq -2$, and half-twists of type $S$ and $Z$.](image)
Theorem 3.2. For \( m \geq 0 \), any Legendrian representative of \( K = K_m \) with maximal \( \text{tb} \) is Legendrian isotopic to the Legendrian knot with front projection depicted in Figure 11, where the rectangle contains \( m \) positive half-twists each of which is of type \( X \).

\[ \text{Fig. 11. A front projection for } K_m \text{ for } m \geq 0, \text{ and crossings of type } X. \]

The techniques developed for the proof of the above theorems also give the following result.

Theorem 3.3. Let \( K \) be a Legendrian representative of the twist knot \( K_m \). Whenever \( \text{tb}(K) < \text{tb}(K_m) \) then \( K \) destabilizes.

We will see below that Theorems 3.2 and 3.3 establish items (1) and (2) in Theorem 1.1, the classification of Legendrian \( K_m \) for \( m \geq -2 \). To classify Legendrian \( K_m \) for \( m \leq -3 \), we need to distinguish between the distinct representatives of \( K_m \) with maximal Thurston–Bennequin number and understand when they become the same under stabilization.

We begin by considering \( K_m \) when \( m \leq -4 \) is even. According to Theorem 3.1, we can represent each of the maximal-tb representatives of \( K_{-2n} \) by a length \( 2n - 2 \) word in the letters \( Z^+, Z^-, S^+, S^- \), where these letters represent the Legendrian half-twists shown in Figure 12 and letters must alternate in sign. Given such a word \( w \), let \( z^+(w), z^-(w), s^+(w), s^-(w) \) denote the number of \( Z^+, Z^-, S^+, S^- \) in \( w \), respectively, and note that \( z^+(w) + s^+(w) = z^-(w) + s^-(w) = n - 1 \).

\[ \text{Fig. 12. Denoting a maximal-tb twist knot by a word in } Z \text{'s and } S \text{'s.} \]

Lemma 3.4. Two words of length \( 2n \) with the same \( z^+, z^-, s^+, s^- \) correspond to Legendrian-isotopic knots.

Proof. A local computation (Figure 13) shows that \( S^\pm S^\mp Z^\pm \) and \( Z^\pm S^\mp S^\pm \) are Legendrian isotopic as Legendrian tangles. (Alternatively, the fact that these are Legendrian...
Fig. 13. Legendrian isotopy between SSZ and ZSS.

isotopic follows from the Legendrian satellite construction [NT]. Similarly, $Z^\pm Z^\pm S^\pm$ and $S^\pm Z^\pm Z^\pm$ are Legendrian isotopic. It follows that we can transpose consecutive $+$ letters in a word while preserving Legendrian-isotopy class, and the same for consecutive $-$ letters. Thus two words with the same $z^+, z^-, s^+, s^-$ that begin with the same sign correspond to Legendrian-isotopic knots.

Fig. 14. Moving a $Z$ from the beginning of a word to the end.

To complete the proof, it suffices to show that $Z^\pm w$ and $wZ^\pm$ correspond to Legendrian isotopic knots for a length $2n - 3$ word $w$, as do $S^\pm w$ and $wS^\pm$. For $Z^\pm w = wZ^\pm$, see Figure 14; for $S^\pm w = wS^\pm$, reflect Figure 14 in the vertical axis. □

By Lemma 3.4, we can define Legendrian isotopy classes $K_{z^+, z^-}$ for $0 \leq z^\pm \leq n - 1$ corresponding to words with the specified $z^+, z^-$. We then have the following result.

**Lemma 3.5.** The Legendrian isotopy classes $K_{z^+, z^-}$ and $K_{n-1-z^+, n-1-z^-}$ are the same.

**Proof.** The map $(x, y, z) \mapsto (-x, -y, z)$ is a contactomorphism of $\mathbb{R}^3$ that preserves Legendrian isotopy classes, as can easily be seen in the $xy$ projection, where it is a rotation by $180^\circ$. In the $xz$ projection, this map sends tangles $Z^\pm$ to $S^\pm$ and $S^\pm$ to $Z^\pm$ and thus sends $K_{z^+, z^-}$ to $K_{n-1-z^+, n-1-z^-}$.

We are now in a position to classify the $K_{z^+, z^-}$’s and all Legendrian knots obtained from the $K_{z^+, z^-}$’s by stabilization. The key ingredients are a result of Ozsváth and Stipsicz [OS] on distinct transverse representatives of twist knots, and the ruling invariant discussed in
Section 2.2. Let $St^+$, $St^-$ denote the operations on Legendrian isotopy classes given by positive and negative stabilization.

**Proposition 3.6.** For $0 \leq z^\pm, z'^\pm \leq n - 1$, we have:

1. $K_{z^+, z^-}$ is Legendrian isotopic to $K_{z'^+, z'^-}$ if and only if $(z^+, z^-) = (z'^+, z'^-) = (n - 1 - z^+, n - 1 - z^-)$;

2. $K_{z^+, z^-}$ and $K_{z'^+, z'^-}$ are Legendrian isotopic after some positive number of positive stabilizations if and only if $z'^\pm = z^\pm$ or $z'^\pm = n - 1 - z^\pm$, and in these cases the knots are isotopic after one positive stabilization;

3. $K_{z^+, z^-}$ and $K_{z'^+, z'^-}$ are Legendrian isotopic after some positive number of negative stabilizations if and only if $z^\pm = z'^\pm$ or $z^\pm = n - 1 - z'^\pm$, and in these cases the knots are isotopic after one negative stabilization;

4. $St^+ St^- K_{z^+, z^-}$ is Legendrian isotopic to $St^+ St^- K_{z'^+, z'^-}$ for all $z^\pm, z'^\pm$.

**Proof.** We first establish (3). It is well-known [EFM] that $Z^-$ and $S^-$ become Legendrian isotopic after one negative stabilization; see Figure 15. Consequently, for $z^- < n - 1$, $St^- K_{z^+, z^-} = St^- K_{z'^+, z'^-} + 1$, and thus $St^- K_{z^+, z^-} = St^- K_{z'^+, z'^-} = St^- K_{n-1-z^+, z^-}$ for any $z^+, z^-, z'^+, z'^-$. It follows from this that there is exactly one $\rho$-graded ruling of the front unless $\rho \mid 2(z^+ + z^- - 1)$, in which case there are two $\rho$-graded rulings; see Figure 15.

It remains to establish (1). The “if” part follows from Lemma 3.5. For “only if”, we use graded ruling invariants; one could also use Legendrian contact homology [C]. The Maslov degrees of the two uppermost (clasp) crossings in a representative front diagram for $K_{z^+, z^-}$ are readily seen to be $\pm 2(z^+ + z^- + 1 - n)$. It follows from this that there is exactly one $\rho$-graded ruling of the front unless $\rho \mid 2(z^+ + z^- + 1 - n)$, in which case there are two $\rho$-graded rulings; see Figure 16.

Now suppose that $K_{z^+, z^-} = K_{z'^+, z'^-}$. By Proposition 2.4, we must have $|z^+ + z^- + 1 - n| = |z'^+ + z'^- + 1 - n|$. On the other hand, by (2) and (3), $z'^\pm \in \{z^\pm, n - 1 - z^\pm\}$ and $z'^\pm \in \{z^\pm, n - 1 - z^\pm\}$. Combined, these equations imply that $(z^+', z^-') = (z^+, z^-)$ or $(n - 1 - z^+, n - 1 - z^-)$, as desired. $\square$

**Fig. 15.** $Z$ and $S$ tangles are isotopic after an appropriate stabilization of each.
We next consider $K_m$ when $m \leq -3$ is odd, say $m = -2n - 1$; the argument here is similar to, but simpler than, the case of $m \leq -4$ even. According to Theorem 3.1, we can represent each of the maximal-tb representatives of $K_{-2n-1}$ by a length $2n - 1$ word in the letters $Z^+, Z^-, S^+, S^-$, where these letters represent the Legendrian half-twists shown in Figure 12 and letters must alternate in sign and begin and end with the same sign. The Legendrian isotopy at the end of the proof of Lemma 3.4 shows that we may assume that the word begins (and ends) with a letter with a plus sign. As above, given such a word $w$, let $z^+(w), z^-(w), s^+(w), s^-(w)$ denote the number of $Z^+, Z^-, S^+, S^-$ in $w$, respectively, and note that $z^+(w) + s^+(w) = z^-(w) + s^-(w) + 1 = n$.

Essentially the same proof as for Lemma 3.4 gives the following result.

**Lemma 3.7.** Two words of length $2n - 1$ with the same $z^+, z^-, s^+, s^-$ correspond to Legendrian-isotopic knots.

By Lemma 3.7, we can define Legendrian isotopy classes $K_{z^+, z^-}$ for $0 \leq z^\pm \leq n$ corresponding to words with the specified $z^+, z^-$. We then have the following result.

**Lemma 3.8.** The Legendrian isotopy classes $K_{z^+, z^-}$ and $K_{n-z^+, n-1-z^-}$ are the same. If $z^+ < n$ and $z^- \geq 1$, then the Legendrian isotopy classes of $K_{z^+, z^-}$ and $K_{z^+, z^-+1}$ are the same.

**Proof.** The first statement follows as in the proof of Lemma 3.5. For the second statement, let $S^+ Z^- w'$ be a word representing $K_{z^+, z^-}$, where $w'$ is some word of length $2n - 3$; then $Z^+ S^- w'$ represents $K_{z^+, z^-+1}$. The isotopy in Figure 14 shows that $Z^+ S^- w'$ and $S^- w' S^-$ correspond to Legendrian isotopic knots, while the reflection of this isotopy in the $z$ axis shows that $S^+ Z^- w'$ and $Z^- w' S^-$ correspond to Legendrian isotopic knots. But $S^- w' Z^-$ and $Z^- w' S^-$ are also Legendrian isotopic by Lemma 3.7.

It follows from Theorem 3.1 and Lemma 3.8 that every maximal-tb knot has a representative of the form $K_{n, z^-}$ for some $0 \leq z^- \leq n - 1$; we denote this representative by $K_{z^-}$.

**Proposition 3.9.** For $0 \leq z^-, z'^- \leq n - 1$, we have:

1. $K_{z^-}$ is Legendrian isotopic to $K_{z'^-}$ if and only if $z'^- = z^-;
2. St^\pm K_{z^-}$ is Legendrian isotopic to $St^\pm K_{z'^-}$ for all $z^-, z'^-$. 

Proof. The proof of (2) is exactly the same as the proof of (2) and (3) in Proposition 3.6. For item (1) we again use \( \rho \)-graded rulings. As in the proof of Proposition 3.6, all of the crossings in \( K_{z^-} \) have Maslov degree 0, except for the top two crossings, which have grading \( \pm (2z^- + 1) \). So \( K_{z^-} \) has one \( \rho \)-graded ruling unless \( 2z^- + 1 \) is divisible by \( \rho \), in which case it has two. By Proposition 2.4, \( K_{z^-} \) and \( K_{z^-}' \) cannot be Legendrian isotopic unless \( z^- = z'^- \).

We are now ready for the proof of our main theorem.

Proof of Theorem 1.1. We begin with items (1) and (2) of the theorem concerning the knot type \( K_m \) with \( m \geq 0 \) (the case \( m = -2 \) is covered by (4)). Theorem 3.2 says that there is a unique Legendrian representative for \( K_m \) with maximal Thurston–Bennequin number if orientations are ignored. For \( m \) odd, when we take orientations into account, there are two maximal tb representatives \( K_+ \) and \( K_- \) of \( K_m \) and they are distinguished by their rotation numbers, \( \text{rot}(K_+) = \pm 1 \). Using the isotopy described in the proof of Lemma 3.5, one easily verifies that \( S_{\theta}^{-}(K_+) \) is Legendrian isotopic to \( S_{\theta}^{+}(K_-) \). Since Theorem 3.3 says that all other representatives destabilize to \( K_{\pm} \), we conclude that \( K_m \) is Legendrian simple if \( m \geq 1 \) is odd. When \( m \geq 0 \) is even, one may again use the isotopy described in the proof of Lemma 3.5 to check that the two oriented Legendrian representatives of \( K_m \) coming from Theorem 3.2 are Legendrian isotopic. Thus there is a unique representative of \( K_m \) with maximal Thurston–Bennequin number and all other Legendrian representatives are stabilizations of this one. This completes the proof for \( m \geq 0 \).

Next consider the case when \( m \) is negative and even. The maximal Thurston–Bennequin number representatives of \( K_{-2n} \) are of the form \( K_{z^+, z^-} \) for \( z^+, z^- \in [0, \ldots, n-1] \), by Theorem 3.1. (This is even true after considering possible orientations, since the orientation reverse of \( K_{z^+, z^-} \) is \( K_{z^-, z^+} \).) Moreover, Proposition 3.6 says \( K_{z^+, z^-} = K_{z'^+, z'^-} \) if and only if \( (z^+, z^-) = (z'^+, z'^-) \) or \( (z^+, z^-) = (n-1-z^+, n-1-z^-) \). Since there are \( n \) choices for \( z^+ \) and \( z^- \) it is clear that there are \( \lceil n^2/2 \rceil \) distinct representatives. Similarly we see that after strictly positive or strictly negative stabilizations there are \( \lceil n/2 \rceil \) distinct representatives and after both types of stabilizations there is just one representative. This completes the proof for (4) of the theorem.

Similarly, when \( m = -2n - 1 \) is negative and odd, item (1) in Proposition 3.9 implies there are at least \( n \) Legendrian representatives with maximal tb, while Lemma 3.8 and the discussion around it implies there are at most \( n \). Moreover Theorem 3.3 says all Legendrian representatives with nonmaximal tb destabilize to one of these. Thus item (3) of the theorem is completed by item (2) in Proposition 3.9.

Proof of Theorem 1.2. We use the fact, due in this setting to [EFM], that the negative stable classification of Legendrian knots is equivalent to the classification of transverse knots. More precisely, two transverse knots are transversely isotopic if and only if any of their Legendrian approximations are Legendrian isotopic after some number of negative stabilizations. Then Theorem 1.2 is a direct corollary of Theorem 1.1.
4. Normalizing the front projection

In this section we prove Theorems 3.1–3.3, thus completing the proof of our main Theorem 1.1. To this end, notice that since $K_m$ is a rational knot, we can find an embedded 2-sphere $S$ in $S^3 (= \mathbb{R}^3 \cup \{\infty\})$ intersecting $K_m$ in four points and dividing $K_m$ into unknotted pieces. More precisely, we can choose $S$ as shown in Figure 17, intersecting $K$ in four points labeled 1, 2, 3 and 4 in the figure and separating $S^3$ into two balls $B_{in}$ and $B_{out}$, such that: $K_m$ intersects $B_{out}$ as a (vertical) 2-braid with two negative half-twists, which we denote $K_{out} = K \cap B_{out}$, and $K_m$ intersects $B_{in}$ as a (horizontal) 2-braid with $m$ positive half-twists, which we denote $K_{in} = K \cap B_{in}$.

![Fig. 17. Model of the knot $K_m$, intersecting a 2-sphere $S$ in four points. The closed curve $C$ on $S$ intersects $K_m$ in four points and the closed curve $B$ on $S$ separates the points 1, 2 from 3, 4.](image)

We begin by normalizing the dividing curves on $S$. After this we study the contact structures on the 3-balls $B_{in}$ and $B_{out}$.

4.1. Normalizing the sphere $S$

Throughout this section, we fix a standard model for $K_m$ as shown in Figure 17, and we assume $m \neq -1$. A Legendrian realization $\mathcal{K}$ of $K_m$ defines an isotopy $\psi: S^3 \to S^3$ mapping $K_m$ to $\mathcal{K}$ and $S$ to $\psi(S)$. We can change the isotopy $\psi$ so that $\psi(S)$ is a convex surface, and a standard neighborhood $N$ of $\mathcal{K}$ with meridional ruling curves intersects $\psi(S)$ in four Legendrian unknots. Let $P$ be the sphere with four punctures $P = S \setminus \nu(K_m)$. The position of the pullback $\Gamma_P$ of the dividing curves on $\psi(P)$ depends on the chosen convex representation of $\psi(S)$, and thus on the isotopy $\psi$, but we can always choose $\psi$ so that $\Gamma_P$ is normalized as follows.

**Theorem 4.1.** Let $m \neq -1$, and fix $K_m$ along with a neighborhood $\nu(K_m)$ and the surfaces $S$ and $P$ as above. For any Legendrian realization $\mathcal{K}$ of $K_m$, there exists an isotopy $\psi: S^3 \to S^3$ such that $S$ (and thus $P$) is convex, $\psi(\nu(K_m)) = N$ is a standard contact neighborhood of $\mathcal{K}$, and the pullback $\Gamma_P \subset P$ of the dividing curves on $\psi(P)$ is as shown in Figure 18.

Before proving Theorem 4.1, we establish the following lemma.
Lemma 4.2. If \( m \neq -1 \) and \( K \) is a Legendrian realization of \( K_m \), then there is a Legendrian unknot \( L \) with \( \operatorname{tb}(L) = -1 \) that, in the complement of \( K \), is topologically isotopic to the curve \( B \) in Figure 17.

Proof. There exists some Legendrian knot \( L \) in the topological class of \( B \), disjoint from \( K_m \). Suppose that \( L \) has been chosen so that \( \operatorname{tb}(L) \) is maximal for Legendrians in this class, say \( \operatorname{tb}(L) = -n \) for some \( n > 0 \). We will show that the assumption that \( n > 1 \) leads to a contradiction.

Let \( N_L \) be a standard neighborhood of \( L \) disjoint from \( K \). Set \( Q = \overline{S^3 - N_L} \). Clearly \( Q \) is a solid torus \( S^1 \times D^2 \) with convex boundary, and the boundary has two dividing curves of slope \(-n\). We can assume the ruling curves are meridional and then choose two disks \( D_1 \) and \( D_2 \) in \( Q \) bounding these ruling curves as shown in Figure 19. Specifically, \( \partial Q \setminus (\partial D_1 \cup \partial D_2) \) consists of two annuli \( A_1 \) and \( A_2 \) such that \( A_1 \cup D_1 \cup D_2 \) (after rounding corners) represents the sphere \( S \). We can isotope each \( D_i \) so that a standard neighborhood \( N \) of \( K \) intersects \( D_i \) in two disks with Legendrian boundary (which are meridional ruling curves on \( \partial N \)) and \( D_i \) is convex. Let \( P_i = D_i \setminus N \). Then \( P_i \) is a pair of pants with three boundary components, which we label \( c_{i,1}, c_{i,2}, c_{i,3} \) so that \( c_{i,3} \) is the boundary component contained in \( \partial Q \) and \( c_{i,1}, c_{i,2} \) are ruling curves in \( \partial N \).

Fig. 18. The dividing curves on \( P \) can always be arranged to be as shown (assuming \( m \neq -1 \)).

Fig. 19. The torus \( \partial Q = \partial N_L \) on the left with the disk \( D_1 \) and \( D_2 \) shaded. On the right is the annulus \( A_1 \) and the disks \( D_1 \) and \( D_2 \) whose union can be taken to be \( S \).

Notice that \( \Gamma_{P_i} = \Gamma_P \cap P_i \) intersects each of \( c_{i,1} \) and \( c_{i,2} \) exactly twice and intersects \( c_{i,3} \) exactly \( 2n \) times. If \( \Gamma_D \) has more than two boundary-parallel dividing curves then \( \Gamma_{P_i} \) will have at least one boundary-parallel dividing curve along \( c_{i,3} \) and thus we can use this
to construct a bypass to destabilize $L$ in the complement of $K$. As this is a contradiction, we know the dividing curves on $P_i$ can be described in the following way (see Figure 20 for an illustration): There is a coordinate system on $D_i$ so that:

- $D_i$ is the unit disk in the $xy$ plane;
- $K \cap D_i = \{0, \pm 1/2\}$;
- $C \cap D_i$ is the line segment $x = 0$, where $C$ is as shown in Figure 17;
- $P_i$ is $D_i$ with small disks around $(0, \pm 1/2)$ removed.

Let $A_{i,j}$ be small annular neighborhoods of $c_{i,j}$ in $P_i$, and let $P_i'$ be the closure of the complement of these annuli in $P_i$. For $n > 1$, the dividing curves on $P_i'$ can be assumed to be $n - 2$ horizontal line segments, along with the line segments in $P_i'$ given by $y = \pm 1/2$. In addition, in each $A_{i,j}$, the dividing curves can be assumed to be the obvious extension of the dividing curves in $P_i'$, with some number of half-twists in $A_{i,1}$ and $A_{i,2}$ and some rigid rotation in $A_{i,3}$. To elaborate on this last point, identify the closure of $A_{i,3}$ radially with $S^1 \times [0, 1]$ so that $\Gamma_{P_i} \cap (S^1 \times \{0\})$ is $2n$ equally spaced points $p_1, \ldots, p_{2n}$ in the circle $c_{i,3}$ and $\Gamma_{P_i} \cap (S^1 \times \{1\})$ is the corresponding set of $2n$ points $p_1', \ldots, p_{2n}'$ in the other boundary component of $A_{i,3}$; then in $A_{i,3}$, $\Gamma_{P_i}$ consists of $2n$ nonintersecting segments connecting $p_1, \ldots, p_{2n}$ to $p_1', \ldots, p_{2n}'$ in some (cyclically permuted) order.

After rounding the corners of $D_1 \cup D_2 \cup A_1$, define $A$ to be the annulus $A_1 \cup A_{1,3} \cup A_{2,3}$. Notice that on $A$ there are $2n$ dividing curves running from one boundary component to the other (we know the dividing curves on $A_1$ as $A_1$ is part of $\partial N_L = \partial Q$); let $\Gamma_A$ denote the union of these dividing curves. As above we can choose a product structure $S^1 \times [0, 1]$ on the closure of $A$ so that $S^1$ has length $2n$, $\Gamma_A \cap (S^1 \times \{0\})$ and $\Gamma_A \cap (S^1 \times \{1\})$ each consist of $2n$ equally spaced points, and $\Gamma_A$ connects these two sets of points through $2n$ nonintersecting segments. The dividing curve on the 2-sphere $S$ must be connected since we are in a tight contact structure, and thus the slope $s$ of the curves in $\Gamma_A$ must be relatively prime to $n$.

Define curves $\gamma$ and $\gamma'$ in $S$ as shown in Figure 21. Then $\gamma$ and $\gamma'$ bound disks $D_{out}$ in $B_{out}$ and $D_{in}$ in $B_{in}$, respectively, where both disks are disjoint from $K$. We can assume
that both $\gamma$ and $\gamma'$ intersect the dividing curves of $S$ only in $A$, and that the curve $\gamma$ intersects $A$ in four arcs $\gamma_1, \gamma_2, \gamma_3, \gamma_4$ as shown in Figure 21. If $\gamma$ is isotoped so that it intersects the $P'_i$ in horizontal arcs, then using the above identification of the closure of $A$ with $S^1 \times [0, 1]$, the slopes of $\gamma_i$ can be taken to be $2, 0, n, n - 2$, respectively. Similarly $\gamma'$ intersects $A$ in two parallel linear arcs $\gamma'_1$ and $\gamma'_2$ of slope $nm$.

Legendrian-realize $\gamma$ and $\gamma'$, and make $D_{out}$ and $D_{in}$ convex. If $\gamma$ or $\gamma'$ does not have maximal tb, then $D_{out}$ or $D_{in}$ has at least two boundary-parallel dividing curves and thus there are at least two bypasses for $S \setminus N_L$ in the complement of $K$. (Notice that when there are only two dividing curves the two bypasses are not disjoint; however, we will see below that we will only need one bypass in this case, and in most cases.) Let $c$ be the curve along which one of the bypasses is attached. (Note that since $\gamma'$ bounds a disc in $B_{in}$, the bypass in that case is attached from the back so its action on the dividing curves of $S$ is the mirror of Figure 5.) We will show that in most cases the bypass reduces $n$, leading to a contradiction. In particular, we have the following claim.

**Claim 4.3.** If $c \cap (P'_1 \cup P'_2)$ has at most one component and $n \geq 2$, then we can destabilize $L$ (contradicting the maximality of $tb(L)$) except possibly when $n = 3$, in which case we can change $s$ by 1 or $-1$ depending on whether $c$ is on $\gamma$ or $\gamma'$.

**Remark 4.4.** In the proof below notice that when $n = 3$ we can sometimes destabilize $L$ and sometimes change $s$. In the exceptional case when $L$ does not destabilize notice that $s$ must be relatively prime to $n$. Thus we can only attach such an exceptional bypass once and any subsequent bypasses attached from the same side of $S$, if it exists, cannot be exceptional and must then provide a destabilization of $L$.

We first prove the claim, then use it to complete the proof of the lemma.

**Proof of Claim.** First note that if $c \cap (P'_1 \cup P'_2) = \emptyset$, then when we attach the bypass to $A$, we see a destabilization for $L$ in the complement of $K$, which contradicts the maximality of $tb(L)$. Thus to prove the claim, we may assume that $c \cap (P'_1 \cup P'_2)$ has one component. We treat the cases $n \geq 4$, $n = 3$, and $n = 2$ separately. For $n \geq 4$, there are eight subcases
shown in Figure 22. The subcases for $\gamma'$ (when the bypass is attached from the back) are the mirrors of these cases. In subcases 3, 4, 7, 8, one can use bypass rotation, Lemma 2.2, to obtain a bypass disjoint from $P'_1 \cup P'_2$ and hence destabilize $L$. The bypasses in subcases 2 and 6 are disallowed: if there is a bypass there then we would have a convex sphere with disconnected dividing set, contradicting tightness. In subcases 1 and 5 we can still destabilize $L$ if $n > 3$. Thus we contradict the minimality of $n$ in all subcases except when $n \leq 3$.

For $n = 3$, we argue as above except for subcases 1 and 5. In these cases, notice that attaching the bypass does not destabilize $L$ but it does alter the dividing curves. Specifically pushing across the bypass adds 1 to (or, in the case of $\gamma'$, subtracts 1 from) the slope of $\Gamma_A$ once we have renormalized everything after attaching the bypass. Thus we see that when $n = 3$ we can either destabilize $L$ or change the slope of $s$ by 1. This establishes the $n = 3$ case of the claim.

Finally, for $n = 2$, there are four subcases analogous to Figure 22. It is readily checked, as above, that two of these are disallowed by tightness, while the other two lead to destabilizations of $L$. \hfill \Box

We now return to the proof of Lemma 4.2. Since the statement of the lemma is known for $m = 0, 1, \pm 2$ by the classification of Legendrian unknots, torus knots, and the figure eight knot [EF, EH1], we need only check it for $|m| > 2$. As mentioned in Remark 4.4, there is an exceptional case when $s = 3$ and the destabilization argument cannot be applied directly; we ignore this case for now and return to it at the end of the proof.

Since $\gamma'_i$ and $\gamma'_i$ are parallel, the intersection of $\gamma'$ with $\Gamma_{5,N}$ must be essential. It follows that $|\gamma'_i \cap \Gamma_A| = |s - nm|$ for $i = 1, 2$, since $\gamma'_i$ has slope $nm$ and $\Gamma_A$ has slope $s$. Now if $|\gamma'_i \cap \Gamma_A| \geq 2$ for $i = 1, 2$, then for any bypass $c$ along $\gamma'$, $c \cap (P'_1 \cup P'_2)$ has at most one component. Thus we can apply the claim if $|s - nm| \geq 2$. It is an easy exercise in algebra to check that $|s - nm| \geq 2$ for all $m$ with $|m| > 2$ whenever $n \geq 2$ and $|s| \leq 3n - 2$. This establishes the lemma when $(n, s)$ is in the shaded region in the left diagram of Figure 23.

Similarly, if $|\gamma \cap \Gamma_A| \geq 2$ for all but at most one of $i = 1, 2, 3, 4$ and $|\gamma \cap \Gamma_A| \geq 1$ for the other $i$, then we can apply the claim to at least one of the (at least two) bypasses
Fig. 23. The pairs \((n, s)\) where the destabilization of \(γ'\) gives a bypass satisfying the conditions of Claim 4.3 (left), and the pairs \((n, s)\) where the destabilization of \(γ\) gives a bypass satisfying the conditions of Claim 4.3 (right).

along \(γ\). Now the intersection of \(γ\) and \(Γ_{S,N}\) is essential if the signs of \(s - 2, s, s - n, s - n + 2\) all agree. This is because in this case, a cancellation can only occur around an arc going through one of the \(P_1\)'s, and there the signs of the crossings agree with two of the above signs, so they cannot cancel. Given that the intersection of \(γ\) and \(Γ_{S,N}\) is essential, we have \(|γ_1 \cap Γ_A| = |s - 2|, |γ_2 \cap Γ_A| = |s|, |γ_3 \cap Γ_A| = |s - n|,\) and \(|γ_4 \cap Γ_A| = |s - n + 2|\). Thus we can apply the claim and establish the lemma if the following conditions hold:

- the signs of \(s - 2, s, s - n, s - n + 2\) all agree;
- at least three of \(|s - 2|, |s|, |s - n|, |s - n + 2|\) are \(≥ 2\), and the fourth is \(≥ 1\).

The set of \((n, s)\) for which these conditions hold is the shaded region in the right diagram of Figure 23.

The union of the shaded regions in Figure 23 covers all of the half-plane \(\{(n, s) : n ≥ 2\}\). This covers all possible cases, and thus if \(n ≠ 3\) the knot \(L\) can always be destabilized by the claim, yielding the desired contradiction. When \(n = 3\) notice that we can always find two successive bypass attachments along arcs on \(γ\) or \(γ'\) that intersect \(P_1' \cup P_2'\) at most one time. (To see this, notice that if there are not two bypasses along \(γ'\) then from above we see that \(s = ±nm, ±(nm ± 1)\) or \(±(nm ± 2)\). Given that \(|nm| ≥ 6\) we see that in these cases we can find the two bypasses along \(γ'\).) Thus, Remark 4.4 shows that \(L\) can be destabilized in this case too.

\(\square\)

Proof of Theorem 4.1. Throughout this proof we use the notation established at the beginning of this section and in the proof of Lemma 4.2. In particular notice that \(P = P_1 \cup P_2 \cup A\). We also set \(P' = P_1' \cup P_2' \cup A\), that is, \(P'\) is \(P\) with annular neighborhoods of its boundary removed (in which there can be twisting of the dividing curves).
We begin by using Lemma 4.2 to obtain a Legendrian unknot $L$ with $tb = -1$ as described in the lemma. We then use $L$ to create the pieces $P_1, P_2, A$ mentioned above. We will now analyze these pieces.

Recall that we have identified $A$ with $S^1 \times [0, 1]$ with $S^1$ having length 2, that is, $S^1 = [0, 2]/\sim$, where $\sim$ identifies the endpoints of the interval. We further arrange that the dividing curves $\Gamma_A$ intersect the boundary of $A$ at $[0, 1] \times \{0, 1\}$. In these coordinates the slope of $\Gamma_A$ is some integer. In Figure 24 we show two examples, one on the left with slope 0, and one on the right with slope 1. All other slopes can be obtained from one of these examples by applying some number of Dehn twists along a curve parallel to the boundary of $A$.

As in the proof of Lemma 4.2, we notice that there is always a bypass for $P'$ on the disk $D_{\text{out}}$ with boundary $\gamma$. Suppose the bypass is attached to $P'$ along a curve $c$. There are three cases to consider: (1) $c$ is disjoint from $P_1 \cup P_2$; (2) it has an endpoint in $P_1$ or $P_2$; or (3) the center intersection point of $c$ with $\Gamma_P$ is contained in $P_1$ or $P_2$. (Notice that the last two cases do not have to be disjoint if the slope of $\Gamma_A$ is near zero.) We consider further subcases depending on the slope of $\Gamma_A$, which we denote by $s$.

If $s > 2$, then case (1) results in a reduction of the slope by 2, case (2) results in a reduction of the slope by 1, and case (3) is disallowed since it results in a disconnected dividing curve on $S$, contradicting the tightness of the standard contact structure on $S^3$. Thus in this case, we can attach bypasses to $P$ to arrange that $s = 2, 1, \text{ or } 0$.

If $s < -1$, then cases (1) and (2) are disallowed, and case (3) increases the slope by 1. Thus in this case we can assume that $s = -1$.

We have now arranged that $s = 2, 1, 0, \text{ or } -1$. If $s = -1$, then there are ten possible bypass attachments. Most are disallowed, while the ones that are allowed can be used, after bypass rotation using Lemma 2.2, to increase the slope of $\Gamma_A$ to 0. If $s = 0$, then there are six possible places for a bypass along $\gamma$; see the left hand side of Figure 24. Of these, two give a disallowed bypass and the other four, after bypass rotation using Lemma 2.2, can be used to increase the slope of $\Gamma_A$ to 1.

If $s = 2$, then there are ten possible bypass attachments. Of these, four reduce the slope to 1, and four are disallowed. The remaining two change the dividing curve on $P$ to the one shown in Figure 25 with $s = 3$. Examining the eight possible bypasses in this new situation, one sees that six are disallowed and the remaining two return $\Gamma_P$ to the configuration with $s = 1$. 

![Fig. 24. On the left the dividing curves have slope 0 on A, while on the right they have slope 1.](image-url)
We have proved that the dividing curves on $P'$ can be made to look like those in Figure 18. To complete the proof of the theorem, notice that we have a standard neighborhood $N$ of $K$ as claimed and the dividing curves on $P$ can differ from those in the figure only by twisting in the annuli $A_{i,j}$ with $i, j = 1, 2$. We can add a small neighborhood of the annuli $A_{i,j}$ to $N$ to get a new standard neighborhood of $K$ (notice the slope of the dividing curves does not change as the neighborhood is increased to contain the annuli) and the surface $P'$ for the old neighborhood is the surface $P$ for the new neighborhood. This completes the proof of the theorem. \hfill \Box

4.2. The contact structure in $B_{\text{out}}$

In this subsection we prove that either the Legendrian knot $K$ destabilizes or the Legendrian tangle in $B_{\text{out}}$ is determined.

**Theorem 4.5.** Let $K$ be a Legendrian knot in the knot type $K_m$, $m \neq -1$. Assume we have chosen an identification of $K$ with the standard model as in Theorem 4.1. Let $D = \{x^2 + z^2 \leq 1\} \times \{y = 0\}$ be a convex disk in $\mathbb{R}^3 \subset S^3$. Then either $K$ destabilizes or there is a contactomorphism from $B_{\text{out}}$ to the complement of (the interior of) a standard neighborhood $\{(x, y, z) \mid x^2 + z^2 \leq 1, y^2 \leq 1\}$ of $D$ in $S^3$ (with corners rounded) taking $K \cap B_{\text{out}}$ to the curves shown in Figure 26.

We notice that the dividing curves on the boundary of the ball in Figure 26 and the ones on $B_{\text{out}}$ in Figure 18 are not the same but that there is a diffeomorphism of the ball that takes one set of curves to the other.
Proof. Let $B$ be the complement of the interior of a neighborhood of $D$ in $S^3$ with corners rounded and let $l_1$ (left) and $l_2$ (right) be the two Legendrian arcs in $B$ shown in Figure 26. Let $N_1 = D^2 \times [0, 1]$ and $N_2 = D^2 \times [0, 1]$ be product neighborhoods of $l_1$ and $l_2$, respectively. We can assume each $N_i \cap \partial B$ consists of two disks, each of which intersects the dividing curve $\Gamma_{\partial B}$ in an arc. We can further assume that the characteristic foliation of $\partial B$ has the boundary of these disks as the union of leaves, and we can arrange that $\partial N_i$ is convex.

Notice that $H = B \setminus (N_1 \cup N_2)$ is a genus 2 handlebody whose boundary is a surface with corners. Two disks $D_1$ and $D_2$ that cut $H$ into a 3-ball are indicated in Figure 28. (To see where the disks come from, notice that one can isotope the picture into a standardly embedded genus 2 handlebody in $S^3$ by isotoping the neighborhoods $N_1$ and $N_2$ so that they do not twist around each other. See Figure 27. The disks are now obvious. Isotoping back to the original picture, once can track the boundaries of the disk to obtain Figure 28.)

![Fig. 27](image)

**Fig. 27.** On the right hand side we see there is an obvious disk bounded by the dotted curve and one of the arcs in $B$. The boundary of this disk is shown in the middle and left hand pictures after the arcs in $B$ are isotoped. On the right hand side we see the boundary of a disk that will provide a compressing disk for $H$.

![Fig. 28](image)

**Fig. 28.** The thicker curve bounds a disk $D_1$ in $H$. The disk $D_2$ can be seen by reflecting this picture about a vertical line. The thinner curves depict the dividing curves.

We now proceed to see what data determines the contact structure on $H$. A contact structure on a neighborhood $N_b$ of $\partial H$ is determined by the characteristic foliation on $\partial H$. We can find a slightly smaller handlebody $\tilde{H}$ in $H$ such that $\partial \tilde{H}$ is contained in $N_b$ and is obtained by rounding the corners of $\partial H$. Let $D_i = D_i \cap \tilde{H}$, and Legendrian-realize $L_i = \partial D_i$ on $\partial \tilde{H}$. 
Now $L_i$ intersects the dividing set $\Gamma_{\hat{H}}$ in four points, three of these points in (the part of $\partial \hat{H}$ coming from) $\partial N_i$ (notice that $\partial D_i \cap \partial N_i$ intersects the dividing set efficiently, i.e., minimally in its homology class) and one point $x$ in (the part of $\partial \hat{H}$ coming from) $\partial B$. Thus we clearly have $tb(L_i) = -2$.

Moreover, we can see that neither of the two boundary-parallel dividing curves on $\hat{D}_i$ straddles the point $x$, as follows. If one did, then the other dividing curve would give a bypass attached along $\partial N_i$. Attaching the bypass to $\partial \hat{H}$ will result in a surface $\Sigma$ of genus two and a curve $\gamma$, which corresponds to $\partial \hat{D}_i$ on $\partial \hat{H}$. The curve $\gamma$ will intersect the dividing curves on $\Sigma$ twice. Compressing $\Sigma$ along a meridional disk to $N_i + 1$ (where we use the convention that $N_3 = N_1$) will result in a convex torus $T$ on which $\gamma$ sits. One may also think of $T$ as obtained by attaching the bypass to $\partial (B \setminus N_i + 1)$. The curve $\gamma$ will intersect the dividing curves on $\Sigma$ twice. Compressing $\Sigma$ along a meridional disk to $N_i + 1$ (where we use the convention that $N_3 = N_1$) will result in a convex torus $T$ on which $\gamma$ sits. (One may also think of $T$ as obtained by attaching the bypass to $\partial (B \setminus N_i + 1)$.) The curve $\gamma$ is an essential curve in the torus $T$ and bounds a disk in the complement of $T$. Moreover, while it intersects the dividing set twice, it can be isotoped to be disjoint from it. Thus $\gamma$ can be Legendrian-realized, resulting in an unknot with $tb = 0$ which contradicts tightness.

The dividing set on $\hat{D}_i$ has now been completely determined, and so the contact structure on $H$ is completely determined by the characteristic foliation on $\partial H$ (and after isotoping the boundary slightly, by $\Gamma_{\partial H}$).

We now turn our attention to $K$. We assume we have normalized $K$, a neighborhood of $K$, and the sphere $S$ as in Theorem 4.1. Let $l'_{1}$ and $l'_{2}$ be the Legendrian arcs that are the components of $K \cap B_{\text{out}}$, and $N'_{1}$ and $N'_{2}$ the components of $N \cap B_{\text{out}}$. The set $H' = B_{\text{out}} \setminus (N'_{1} \cup N'_{2})$ is a handlebody of genus 2 whose boundary is a surface with corners. We can choose disks $D'_{1}$ and $D'_{2}$ as shown in Figure 29. Notice that this figure differs from Figure 26 by a diffeomorphism of $B_{\text{out}}$ and agrees with Figure 17 and the conclusion in Theorem 4.1. (We should take a neighborhood of $\partial H'$ and then take another copy of the handlebody with the corners on the boundary rounded as we did above, but for simplicity we will not include this in the notation.) Legendrian-realize $L'_{i} = \partial D'_{i}$. We see that $L'_{i}$ intersects the dividing set on $\partial B_{\text{out}}$ exactly twice, once near $N'_{1}$ and this intersection point can be assumed to be on $N'_{1}$) and once at some point $y$. While the intersection is efficient, as above, if we consider $\partial (B_{\text{out}} \setminus N'_{1})$ then the intersection is inefficient. If $tb(L_i) \leq -3$ then there is a bypass for $\partial N_i \cap \partial H'$ along $D'_{i}$.

Fig. 29. The thicker curve bounds a disk $D'_{1}$ in $H'$. The disk $D'_{2}$ can be seen by reflecting this picture about a vertical line.
Notice that $K_m$ bounds a singular disk $D'$ with a single clasp singularity.

**Claim 4.6.** The bypass above coming from $D'_i$ can be thought of as a bypass along $\partial D'$.

Notice that the framing given to $K_m$ by $D'$ is $(-1)^m$. From Proposition 2.6, the maximal Thurston–Bennequin number of $K_m$ is $\leq 1$ when $m$ is even and $\leq -1$ when $m$ is odd; it follows that the contact framing on $K$ is always less than or equal to the framing given by $D'$. Thus a bypass along $\partial D'$ always gives a destabilization of $K$.

To clarify what the claim says, recall that the effect of attaching a bypass to a convex surface is entirely determined by its arc of attachment. Thus as long as the arc of attachment for a bypass on $D'_i$ is a subset of $\partial D'$, we may assume it is a bypass on $D'$ as far as its effect on $\partial N$ is concerned.

**Proof of Claim.** Notice that $\partial D'$ can be broken into two parts $c_1 = \partial D' \cap N_i$ and $c_2 = (\partial D') \setminus c_1$. Moreover we can assume that $c_1 = \partial D'_i \cap N_i$. If $c_1$ intersects the dividing curves on $\partial N_i$ efficiently then with the appropriate orientations on $c_1$ and the dividing curves, all the intersections between $c_1$ and the dividing curves are negative, since if not then we could add a neighborhood of a Legendrian arc in $B_{in}$ to $N_i$ to construct a neighborhood of a Legendrian unknot with nonnegative Thurston–Bennequin number, contradicting tightness. We can similarly assume $c_2$ negatively intersects the dividing curves on $N \setminus N_i$, where the orientation on the dividing curves and $c_2$ are consistent with the orientations chosen for the dividing curves on $N_i$ and $c_1$. We have shown that we can arrange that $\partial D'$ intersects the dividing curves on $\partial N$ efficiently and $\partial D' \cap N_i = \partial D'_i \cap N_i$. Hence any bypass along $\partial D'_i$ for $\partial N_i$ can be thought to be a bypass attached along $\partial D'$.

We assume for the remainder of this proof that $K$ does not destabilize. It follows from the above discussion that $tb(L'_i) = -2$ or $-1$. Arguing as we did for the standard model above, we see that $tb(L'_i)$ cannot equal $-1$, so we may assume $tb(L'_i) = -2$. Moreover, as above, we see that neither of the two boundary-parallel dividing curves on $D'_i$ can straddle $y$. Thus the configuration of the dividing curves $\Gamma_{D'_i}$ is determined, and the contact structure on $H'$ is determined by the characteristic foliation on $\partial H'$.

We can thus find a diffeomorphism $\phi : B \to B_{out}$ that preserves the dividing set on the boundary and takes $l_1$ to $l'_1$ and $D_1$ to $D'_1$. Since $\phi$ can be isotoped to be a contactomorphism in a neighborhood of $(\partial B) \cup l_1 \cup l_2$ and the dividing curves on $D_1$ and $D'_1$ are determined above, we can isotope $\phi$ to be a contactomorphism from $B$ to $B_{out}$ taking $l_1 \cup l_2$ to $l'_1 \cup l'_2 = K \cap B_{out}$.

4.3. The contact structure in $B_{in}$ and braids

The disc $D = \{x^2 + z^2 \leq 1\} \times \{y_0\}$ is convex in $(S^1, \xi_{st})$ with dividing curve $\Gamma_D = \{0\} \times [-1, 1] \times \{y_0\}$. Fix $m$ points $\{(1 + \frac{2i}{m+1}, y_0, 0)\}_{i=1}^m$ on $\Gamma_D$. Then the fronts of Legendrian braids in $D \times [-1, 1]$ with endpoints $\{(-1 + \frac{2i}{m+1}, -1, 0)\}_{i=1}^m \cup \{(-1 + \frac{2i}{m+1}, 1, 0)\}_{i=1}^m$ are described as follows:

**Theorem 4.7** (Etnyre and Vértesi [EV]). The Legendrian representations of a braid in $D \times [-1, 1]$ are built up from the building blocks of Figure 30.
Fig. 30. Building blocks of Legendrian braids. There can be other horizontal strands, not depicted, above and/or below the strands shown.

Note that $Z(0, 1)$ and $S(1, 0)$ are just stabilizations. Using Theorem 4.7 we can understand Legendrian braids with two strands; we will write $Z = Z(1, 1)$, $X = X(1, 1)$, $S = S(1, 1)$. Notice that if $Z$ or $S$ is followed by $X$ or vice versa then it destabilizes, see Figure 31. This observation immediately yields the following result.

Fig. 31. $S = S(1, 1)$ followed by $X = X(1, 1)$ is Legendrian isotopic to a trivial braid with one stabilization.

**Proposition 4.8.** Consider a braid with two strands and $n$ half-twists.

1. If $n \geq 0$ then a Legendrian representation of $B$ either destabilizes or consists of $n$ blocks of type $X$.
2. If $n < 0$ then a Legendrian representation of $B$ either destabilizes or is built up from $n$ building blocks of type $S$ and $Z$ in any order. $\square$

This proposition allows us to understand $K \cap B_{in}$.

**Theorem 4.9.** Let $K$ be a Legendrian knot in the knot types $K_m, m \neq -1$. Either $K$ destabilizes, or the contactomorphism from $B_{out}$ to a ball in $S^3$ given in Theorem 4.5 can be extended to $B_{in}$, giving a contactomorphism from $S^3$ to itself that maps $K \cap B_{in}$ to a Legendrian braid on two strands with $m + 2$ twists.

**Proof.** The contactomorphism clearly extends as a diffeomorphism and since there is a unique contact structure up to isotopy on the 3-ball, we can isotope this diffeomorphism (relative to $B_{out}$) to a contactomorphism on $B_{in}$. The image of $K \cap B_{in}$ is clearly a Legendrian 2-braid with $m + 2$ twists. $\square$

We are now ready to simultaneously prove Theorems 3.1–3.3.

**Proof of Theorems 3.1–3.3.** If $m \neq -1$, let $K$ be a Legendrian realization of $K_m$. From the previous theorem either $K$ destabilizes or there is a contactomorphism of $S^3$ taking $K$ to one of the Legendrian knots shown on the left of Figure 10; note that the box shown there is a Legendrian 2-braid. If there is not an obvious destabilization of the 2-braid, then
by Proposition 4.8, it is obtained by stacking $|m + 2|$ $S$’s and $Z$’s together if $m \leq -2$, or $m + 2$ $X$’s if $m \geq 0$. Clearly this agrees with Figure 10 for $m \leq -2$, but also notice that for $m \geq 0$ this gives a knot isotopic to the one in Figure 11. Since Legendrian isotopy in the standard contact structure on $S^3$ is the same as ambient contactomorphism (i.e., a contactomorphism sending one Legendrian knot to the other) [El1], this completes the proof once we know that the knots shown in Figures 10 and 11 do not destabilize. But this is the content of Proposition 2.6.

Acknowledgments. This paper was initiated by discussions between the last two authors at the workshop “Legendrian and transverse knots” sponsored by the American Institute of Mathematics in September 2008. We also thank Ko Honda and András Stipsicz for helpful discussions and Whitney George and the referee for valuable comments on the first draft of the paper.
