We present improved theoretical calculations of transition frequencies for the fundamental transitions \((L=0, v=1) \rightarrow (L'=0, v'=0)\) in the hydrogen molecular ions \( \text{H}_2^+ \) and HD\(^+\) with a relative uncertainty \(4 \times 10^{-11}\) and for the two-photon transitions in the antiprotonic helium atom with a relative uncertainty \(10^{-10}\). To do that, the one-loop self-energy correction of order \(\alpha(Za)^6\) is derived in the two Coulomb center approximation, and numerically evaluated in the case of the aforementioned transitions. The final results also include a complete set of other spin-independent corrections of order \(m\alpha^7\). The leading order corrections of \(\alpha^2\ln^2(Za)^{-1}(Za)^6\) are also considered that allows to estimate a magnitude of yet uncalculated contributions.

I. INTRODUCTION

The few-body bound-state quantum electrodynamics is a challenging problem. So far, a complete set of contributions up to order \(m\alpha^6\) has been obtained and calculated for the two-electron helium-like atoms \(^1\), one-electron molecular ions \(^2\), and antiprotonic helium \(^3\). A contribution of \(m\alpha^7\) order including as well the non-logarithmic part, has been obtained for the fine structure of helium \(2P\) level in \(^4\). Four-particle systems were addressed in \(^5\) \(\text{H}_2\) and its isotopologues and in \(^6\) (lithium-like atoms). Recently, QED calculations up to \(m\alpha^5\), and partially \(m\alpha^6\) orders were carried out for the beryllium atom with four electrons \(^7\).

Progress in high-precision spectroscopy of three-body molecular or molecule-like systems has opened new possibilities for metrology of nucleus-to-electron mass ratios \(^8\). One-photon ro-vibrational transitions were observed in HD\(^+\) molecular ion with a relative uncertainty of 1-2 ppb \(^9\) \(^10\). Spectroscopy of two-photon transitions in antiprotonic helium at the 2-5 ppb level yielded a new value of the antiproton-to-electron mass ratio \(^11\). These experiments, as well as others \(^12\) \(^13\), are currently being developed towards higher precision, which motivates the evaluation of higher-order corrections in these systems. The importance of the \(m_p/m_e\) problem is supported by recent experiments \(^14\) with rubidium atoms, which allow to deduce a new value of the fine structure constant, \(\alpha = e^2/(\hbar c)\), with a relative uncertainty \(6.6 \times 10^{-10}\). Further improvement may be hindered by the present limits on the proton-to-electron mass ratio, which is determined by the latest CODATA adjustment \(^15\) with a relative uncertainty \(4.1 \times 10^{-10}\) (see also \(^16\)).

Theoretical calculation of the complete set of QED corrections up to order \(m\alpha^6\) has brought the theoretical uncertainty down to 0.3-0.4 ppb in \(\text{H}_2^+\) or HD\(^+\) \(^2\), and about 1 ppb in antiprotonic helium \(^3\). Very accurate leading order relativistic corrections are also available from \(^17\). In the present work, we compute the complete set of \(m\alpha^7\) order corrections including the one-loop self energy contribution, which represents the main source of theoretical uncertainty. This allows us to improve the accuracy by about one order of magnitude, thus making real the possibility of improving the knowledge of nucleus-to-electron mass ratios.

This paper is organized as follows: In Sec. II the one-loop self-energy contribution at \(m\alpha^7\) order for the hydrogen-like atoms is considered and a general formula for an arbitrary \((n, l)\) state, derived from comparison of \(^18\) \(^19\) \(^20\) \(^21\) results, is presented. In Sec. III the low energy part is reconsidered to reformulate the result of Sec. II in a form which is then suitable to be extended to the Coulomb two-center problem (Sec. IV A). A list of other contributions in \(m\alpha^7\) and \(m\alpha^8\) orders, which were also taken into account in the final results, are considered in Sec. IV B. Then examples of numerical calculations for the hydrogen isotope ions as well as for the antiprotonic helium are given in Sec. V.

II. THE ONE-LOOP SELF-ENERGY CONTRIBUTION AT ORDER \(m\alpha^7\). HYDROGEN-LIKE CASE.

As a starting point of our consideration we take the general result of Refs. \(^18\) \(^19\) for a bound electron in a field of external Coulomb potential, \(V(r) = -Z/r\), written in the natural relativistic units (\(\hbar = c = m = 1\)): 

\[ \text{quantum electrodynamics (QED)} \]
\[
\Delta E^{(7)} = \frac{\alpha}{\pi} \left( (Z\alpha)^6 \mathcal{L}_H + \left( \frac{5}{9} + \frac{2}{3} \ln \left[ \frac{1}{2} (Z\alpha)^{-2} \right] \right) \langle 4\pi \rho \mathcal{Q}(E_0-H)^{-1}Q H_B \rangle + 2 \langle H_{so} \mathcal{Q}(E_0-H)^{-1}Q H_B \rangle \right) \\
+ \left( \frac{779}{14400} + \frac{11}{120} \ln \left[ \frac{1}{2} (Z\alpha)^{-2} \right] \right) \langle \nabla^4 V \rangle + \left( \frac{23}{576} + \frac{1}{24} \ln \left[ \frac{1}{2} (Z\alpha)^{-2} \right] \right) \langle 2i\sigma^{ij} p^i \nabla^2 V p^j \rangle \\
+ \left( \frac{589}{720} \frac{2}{3} \ln \left[ \frac{1}{2} (Z\alpha)^{-2} \right] \right) \langle (\nabla V)^2 \rangle + \frac{3}{80} \langle 4\pi \rho p^2 \rangle - \frac{1}{2} \langle p^2 H_{so} \rangle \right),
\]

where
\[
H_B = -\frac{p^4}{8} + \frac{\pi}{2} \rho + H_{so}, \quad H_{so} = \frac{1}{4} \sigma^{ij} \nabla i V p^j,
\]

and \(\sigma^{ij} = [\sigma^i \sigma^j]/(2i) = \epsilon^{ijk} \sigma^k\). Brackets denote averaging on the nonrelativistic bound state wave function \(\psi_0\), \(E_0\) and \(H = p^2/2 + V\) are, respectively, the nonrelativistic energy of the state and the nonrelativistic Hamiltonian. Here \(Q\) is a projector operator on the subspace orthogonal to \(\psi_0\). \(\mathcal{L}_H\) is the low-energy photon contribution or the relativistic Bethe logarithm for the hydrogen atom state (assuming \(Z = 1\)). The above result is valid for all states with nonzero angular momentum and for the normalized difference of \(S\) states,

\[
\Delta_n = n^3 \Delta E(nS) - \Delta E(1s).
\]

A more general expression which would also be valid for individual \(S\) states, will differ from (7) only by a term proportional to the delta function, \(\delta(r)\). To get the unknown contribution for the hydrogen case, we have to compare with the result of [20, 21] obtained for the 1S state of hydrogen. For this purpose, the expectation values in (1) which are divergent for individual \(S\) states should first be regularized; we will use a regularization by cut-off of a small \(r\) spherical domain around the nucleus. Any two such regularizations differ by a term proportional to the delta function, so that the result will still differ from an expression valid for all states by a delta-function term.

To that end let us introduce two functionals \(Q\) and \(R\)

\[
Q = \lim_{r_0 \to 0} \left\{ \left( \frac{1}{4\pi r^3} \right)_{r_0} + \left( \ln r_0 + \ln \alpha + \gamma_E \right) \langle \delta(r) \rangle \right\} = -\frac{(Z\alpha)^3}{\pi n^3} \left[ -\frac{1}{2} \ln Z^{-2} + \psi(n) - \psi(1) - \ln \frac{n}{2} + \frac{1}{2} \right],
\]

\[
R = \lim_{r_0 \to 0} \left\{ \left( \frac{1}{4\pi r^4} \right)_{r_0} - \left[ \frac{1}{r_0} \langle \delta(r) \rangle + \left( \ln r_0 + \ln \alpha + \gamma_E \right) \langle \delta'(r) \rangle \right] \right\} = 2(Z\alpha)^4 \frac{1}{\pi^3 n^3} \left[ -\frac{1}{2} \ln Z^{-2} + \psi(n) - \psi(1) - \ln \frac{n}{2} - \frac{5}{3} + \frac{1}{2n} + \frac{1}{6n^2} \right],
\]

where

\[
\langle \phi_1 | \delta'(r) | \phi_2 \rangle = \langle \phi_1 | \frac{r}{p} \nabla \delta(r) | \phi_2 \rangle = -\langle \partial_r \phi_1 | \delta'(r) | \phi_2 \rangle - (\delta(\phi_1 | \delta(r) | \phi_2) - (\delta(\phi_1 | \delta(r) | \phi_2)\partial_r \delta),
\]

\(\langle \_ \rangle_{r_0}\) denotes integration outside a sphere of radius \(r_0\). The last line in Eqs. [2, 3] contains an expectation value of \(Q\) (or \(R\)) for \(nS\) states of hydrogen-like atoms. Using these expressions all divergent matrix elements appearing in Eq. [1] may be redefined in a finite form:

\[
\langle 4\pi \rho p^2 \rangle_{fin} = 8\pi(Z\alpha)^2 R + 16\pi(Z\alpha)^3 Q + 4E_0 \langle V^2 \rangle - 2 \langle p V^2 p \rangle + 2E_0 \langle 4\pi \rho \rangle
\]

\[
\langle [\nabla^4 V] \rangle_{fin} = -32\pi(Z\alpha)^3 Q - 8E_0 \langle V^2 \rangle + 4 \langle p V^2 p \rangle + 2 \langle p(4\pi \rho) p \rangle - 4E_0 \langle 4\pi \rho \rangle
\]
$$\langle 4\pi\rho Q(E-H)^{-1}QH_B \rangle_{\text{fin}} = \langle H'^{(1)}Q(E-H)^{-1}QH'^{(2)} \rangle$$

$$+ \frac{1}{4} \left[ 4\pi(Z\alpha)^2 R + 16\pi(Z\alpha)^3 Q + 8E_0 \langle V^2 \rangle - 4E_0^2 \langle V \rangle + \langle H^{(1)} \rangle \langle V \rangle - 8 \langle H^{(2)} \rangle \langle V \rangle \right]$$  \hspace{2cm} (4c)

In the last expression \( H^{(1)} = 4\pi\rho, H^{(2)} = H_B \), which are transformed \cite{23, 24} as

\[
\begin{aligned}
H'^{(1)} &= -(E_0 - H_0)U_1 - U_1(E_0 - H_0) + H^{(1)} \\
H'^{(2)} &= -(E_0 - H_0)U_2 - U_2(E_0 - H_0) + H^{(2)}
\end{aligned}
\]

Thus obtained expression should be compared with the complete result for a 1s state \cite{20, 21}.

\[
\Delta E^{(7)}_{\text{ee}}(1S) = \frac{\alpha(Z\alpha)^6}{\pi} \left\{ -\ln^2 [(Z\alpha)^{-2}] + \left[ \frac{28}{3} \ln 2 - \frac{21}{20} \right] \ln [(Z\alpha)^{-2}] - 30.92414946(1) \right\}  
\] \hspace{2cm} (5)

which yields (using \( \mathcal{L}(1S) = -27.25990948(1) \)) \cite{18}

\[
\Delta E^{(7)}_{\text{ee}} = \frac{\alpha}{\pi} \left\{ (Z\alpha)^6 \mathcal{L}_H + \left( \frac{5}{9} + \frac{2}{3} \ln \left( \frac{1}{2} (Z\alpha)^{-2} \right) \right) \langle 4\pi\rho Q(E-H)^{-1}QH_B \rangle_{\text{fin}} + 2 \langle H_{so} Q(E-H)^{-1}QH_B \rangle \\
+ \left( \frac{779}{14400} + \frac{11}{120} \ln \left( \frac{1}{2} (Z\alpha)^{-2} \right) \right) \langle \nabla^4 V \rangle_{\text{fin}} + \left( \frac{23}{576} + \frac{11}{24} \ln \left( \frac{1}{2} (Z\alpha)^{-2} \right) \right) \langle H^6_{so} \rangle \\
+ \left( \frac{589}{720} + \frac{2}{3} \ln \left( \frac{1}{2} (Z\alpha)^{-2} \right) \right) \langle (\nabla V)^2 \rangle_{\text{fin}} + \frac{3}{80} \langle 4\pi\rho p^2 \rangle_{\text{fin}} - \frac{1}{2} \langle p^2 H_{so} \rangle \\
+ \left\{ \ln (\alpha^{-2}) + \left( \frac{16}{3} \ln 2 - \frac{11}{4} \right) \ln (\alpha^{-2}) + \ln^2 Z^{-2} + \left( \frac{10}{3} \ln 2 + \frac{37}{15} \right) \ln Z^{-2} - 0.81971202(1) \right\} (Z\alpha)^2 \langle \pi\rho \rangle \right\}  
\] \hspace{2cm} (6)

for the hydrogen-like atom.

\section{III. THE LOW-ENERGY PART: REDEFINING THE RELATIVISTIC BETHE LOGARITHM TO ATOMIC UNITS}

From this point and in what follows we will use atomic units: \( m_e = \hbar = e = 1 \).

In expressions (1) and (6), the relativistic Bethe logarithm \( \mathcal{L}_H \) is defined using the energy scale \( Z^2E_h \), which is well suited for the hydrogenic case, but becomes irrelevant for a system with two Coulomb centers of charges \( Z_1, Z_2 \). For this reason, we have to redefine the relativistic Bethe logarithm \( \mathcal{L}(Z,n,l) \) in a.u.

The low-energy part has been considered in more details in \cite{22}. Here we will try to elucidate only the key points of the derivation.

The relativistic Bethe logarithm is determined in integral form as follows

\[
\mathcal{L}(Z,n,l) = \frac{2}{3} \int_0^{E_h} dk \Phi_{\alpha^2}^{(1)}(k) + \frac{2}{3} \int_{E_h}^{\infty} dk \Phi_{\alpha^2}^{(2)}(k),  \hspace{1cm} (7)
\]

where \( E_h \) is the Hartree energy.

The integrand is a function of energy and is a sum of various contributions:

a) relativistic corrections to the wave function

\[
P_{rc}^{(1)}(k) = \langle H_B Q(E_0 - H)^{-1}Qp (E_0 - H - k)^{-1}p \rangle \\
+ \langle p (E_0 - H - k)^{-1} (H_B - \langle H_B \rangle) (E_0 - H - k)^{-1} p \rangle;  \hspace{1cm} (8)
\]

b) modification of the vertex interactions

\[
P_{rc}^{(2)}(k) = \left\langle \left( -p^2 p' - \frac{1}{2} \sigma^{ij} \nabla^i V \right) (E_0 - H - k)^{-1} p' \right\rangle;  \hspace{1cm} (9)
\]
c) nonrelativistic quadrupole contribution

\[ P_{nq}(k) = \frac{3k^2}{8\pi} \int_S d\Omega_n \left( \delta^{ij} - n^i n^j \right) \left\{ \left\langle p^i (n \cdot r) \left( E_0 - H - k \right)^{-1} (n \cdot r) p^j \right\rangle - \left\langle p^i (n \cdot r)^2 \left( E_0 - H - k \right)^{-1} p^j \right\rangle \right\}, \quad (10) \]

where \( k = k \text{n} \).

The complete contribution is \( P_{nq}(k) = P^{(1)}_{nq}(k) + P^{(2)}_{nq}(k) + P_{nq}(k) \). Its asymptotic expansion for large \( k \) may be written in operator form up to terms of \( O(1/k^2) \) (see Appendix for asymptotic expansion of separate contributions):

\[ P_{\alpha^2}(k) = -\frac{1}{2} \left\langle \nabla^2 \right\rangle + \frac{2}{k} \left\langle (H_B - \langle H_B \rangle) \left( E_0 - H \right)^{-1} \nabla^2 \right\rangle + \frac{4}{5k} \left\langle \nabla^4 \right\rangle - \frac{1}{2k} \left\langle \left( \nabla^2 V \right) \right\rangle + \frac{\sqrt{2}}{k^{3/2}} \pi Z^2 \left\langle \delta(r) \right\rangle - \frac{3\ln k}{k^2} \pi Z^3 \left\langle \delta(r) \right\rangle + \frac{5\ln 2 + \frac{37}{10}}{k^2} \pi Z^3 \left\langle \delta(r) \right\rangle + \frac{1}{k^2} \left\langle (H_B - \langle H_B \rangle) \left( E_0 - H \right)^{-1} \nabla^2 V \right\rangle_{\text{fin}} + \frac{1}{k^2} \left\langle \left( \nabla^4 V \right) \right\rangle_{\text{fin}} + \frac{11}{80k^2} \left\langle \left( \nabla^4 V \right) \right\rangle_{\text{fin}} + \frac{1}{16k^2} \left\langle H^4_{\text{fin}} \right\rangle + \ldots \]

The finite expectation values are defined in a similar way as in the previous section, taking into account that the functionals \( Q \) and \( R \) should be accordingly modified:

\[ Q = \lim_{r_0 \to 0} \left\{ \left\langle \frac{1}{4\pi r^3} \right\rangle \right\}, \quad (12) \]

\[ R = \lim_{r_0 \to 0} \left\{ \left\langle \frac{1}{4\pi r^4} \right\rangle - \left[ \frac{1}{r_0} \delta(r) \right] + \left\langle \ln(r_0 + \gamma_E) \delta'(r) \right\rangle \right\}. \quad (13) \]

As is discussed in [18, 22] we have to subtract the leading terms of expansion \( \left( 11 \right) \):

\[ P^{(1)}_{nq}(k) = P_{\alpha^2}(k) - \frac{A_{\alpha^2}}{k} - \frac{B_{\alpha^2}}{k^{3/2}} \]

and

\[ P^{(2)}_{nq}(k) = P_{\alpha^2}(k) - \frac{A_{\alpha^2}}{k} - \frac{B_{\alpha^2}}{k^{3/2}} - \frac{C_{\alpha^2} \ln k}{k^2} - \frac{D_{\alpha^2}}{k^2}. \]

The previous definition of the relativistic Bethe logarithm \( \mathcal{L}_H \) assumes scaling to \( (Z\alpha) = 1 \), and thus it may be expressed in atomic units as

\[ \mathcal{L}_H(n,l) = Z^{-6} \left[ \frac{2}{3} \int_0^{2E_h} dk P^{(1)}_{\alpha^2}(k) + \frac{2}{3} \int_{2E_h}^{\infty} dk P^{(2)}_{\alpha^2}(k) \right]. \quad (15) \]

Comparing \( \left( 15 \right) \) with \( \left( 11 \right) \) one gets a relation between the two definitions of the relativistic Bethe logarithm:

\[ \mathcal{L}(Z,n,l) = Z^6 \mathcal{L}_H(n,l) + \frac{2}{3} \int_{E_h}^{2E_h} \frac{dk}{E_h} \left\{ \left[ \frac{3\ln k}{k} - \frac{1}{k} \left( \frac{5\ln 2 + \frac{37}{10}}{\pi Z^3} \right) \right] \pi Z^3 \left\langle \delta(r) \right\rangle \right\} \]

\[ = Z^6 \mathcal{L}_H(n,l) + \frac{2Z^6}{n^3} \left[ \ln^2 Z^{-2} + \ln Z^{-2} \left( \frac{10}{3} \ln 2 + \frac{37}{15} \right) \right] \]

\[ + \ln Z^{-2} \left[ \frac{2}{3} \left\langle (H_B - \langle H_B \rangle) \left( E_0 - H \right)^{-1} (\nabla^2 V) \right\rangle_{\text{fin}} + \frac{2}{3} \left\langle (\nabla^2 V) \right\rangle_{\text{fin}} + \frac{11}{120} \left\langle (\nabla^4 V) \right\rangle_{\text{fin}} + \frac{1}{24} \left\langle H^4_{\text{fin}} \right\rangle \right] \]

and now substituting this into expression \( \left( 9 \right) \) we immediately get the general expression for the one-loop self-energy...
needs to replace the delta-function distribution, $Z_{\text{atom}}[25]$. arithmetic term for an arbitrary $nS$ matches the result of Erickson and Yennie for the logarithmic term in the case of external electric field of two (or more) Coulomb sources. One may check that the above expression corrects in the $m\alpha^7$ order in atomic units:

$$\Delta E_{\text{se}}^{(7)} = \frac{\alpha^5}{\pi}\left\{ \mathcal{L}(Z,n,l) + \left( \frac{5}{9} + \frac{2}{3} \ln \left[ \frac{\alpha^{-2}}{2} \right] \right) \left( 4\pi \rho Q(E-H)^{-1}Q H_B \right)_{\text{fin}} + 2 \left( H_{so} Q(E-H)^{-1}Q H_B \right)_{\text{fin}} + \left( \frac{779}{14400} + \frac{11}{120} \ln \left[ \frac{\alpha^{-2}}{2} \right] \right) \left( \nabla^4 V \right)_{\text{fin}} + \left( \frac{23}{576} + \frac{1}{24} \ln \left[ \frac{\alpha^{-2}}{2} \right] \right) \left( H_{so}^3 \right)_{\text{fin}} + \left( \frac{589}{720} + \frac{2}{3} \ln \left[ \frac{\alpha^{-2}}{2} \right] \right) \left( \langle \nabla^2 V \rangle^2 \right)_{\text{fin}} + \frac{3}{80} \left( 4\pi \rho p^2 \right)_{\text{fin}} - \frac{1}{2} \left( p^2 H_{so} \right) \right\} \tag{17}$$

This formula is quite general and may be extended to the case of external electric field of two (or more) Coulomb sources. One may check that the above expression matches the result of Erickson and Yennie for the logarithmic term for an arbitrary $nS$ state of the hydrogen atom $[25]$.

IV. COULOMB TWO-CENTER PROBLEM

A. One-loop self energy

For the case of the two-center Coulomb problem one needs to replace the delta-function distribution, $Z^2 \langle \pi \rho \rangle$, in the last line of Eq. (17) by a distribution:

$$V_\delta = \pi \left( Z^3 \delta(r_1) + Z^2 \delta(r_2) \right). \tag{18}$$

To present our results we will adopt a similar notation as for hydrogen-like ions $[20]$.

$$\Delta E_{\text{se}}^{(7)} = \frac{\alpha^5}{\pi} \left[ A_{62} \ln^2[\alpha^{-2}] + A_{61} \ln[\alpha^{-2}] + A_{60} \right]. \tag{19}$$

where $A_{62} = -1$; expressions for $A_{61}$ and $A_{60}$ coefficients are obtained by comparison between Eqs. (17) and (19).

$$A_{61}(R) = \left[ \frac{2}{3} \left( 4\pi \rho Q(E-H)^{-1}Q H_B \right)_{\text{fin}} + \frac{11}{120} \left( \nabla^4 V \right)_{\text{fin}} + \frac{2}{3} \left( \langle \nabla^2 V \rangle^2 \right)_{\text{fin}} + \frac{16}{3} \ln 2 - \frac{1}{4} \right] \left( \langle \pi \rho \rangle \right) / \left( \langle V_\delta \rangle \right) \tag{20}$$

$$A_{60}(R) = \left[ \left( \frac{5}{9} - \frac{2}{3} \ln 2 \right) \left( 4\pi \rho Q(E-H)^{-1}Q H_B \right)_{\text{fin}} + \left( \frac{779}{14400} - \frac{11}{120} \ln 2 \right) \left( \nabla^4 V \right)_{\text{fin}} \right. \left. + \left( \frac{589}{720} - \frac{2}{3} \ln 2 \right) \left( \langle \nabla^2 V \rangle^2 \right)_{\text{fin}} + \frac{3}{80} \left( 4\pi \rho p^2 \right)_{\text{fin}} - 0.81971202(1) \langle \pi \rho \rangle + \mathcal{L}(R) \right] / \left( \langle V_\delta \rangle \right).$$
mental vibrational transition frequency (numerical values of all the correction terms to the fundamental transition frequency we have dropped out the terms from numerical calculations). For comparison, the one-loop self-energy term we have just obtained gives a contribution:

\[ \Delta E_{\text{sc}}^{(7)} \approx 125 \pm 2 \text{ kHz}. \]  

The uncertainty here is primarily due to numerical inaccuracy in the calculated data for the relativistic Bethe logarithm \[22\].

1. The one-loop vacuum polarization:

\[ \Delta E_{\text{cp}}^{(7)} = \frac{\alpha^5}{\pi} \left[ V_{61} \ln(Z\alpha)^{-2} + V_{60} \right] \langle V_6 \rangle \approx 2.9 \text{ kHz}. \]  

For S-states in the hydrogen atom these coefficients are

\[
\begin{align*}
V_{61}(nS) &= -\frac{2}{15}, \\
V_{60}(nS) &= \left\{ \begin{array}{ll}
\frac{4}{15} & \left[ -\frac{431}{105} + \psi(n+1) - \psi(1) \right] + \frac{1}{2(2n-1)} - \frac{1}{28n^2} - \ln \frac{n}{2} \end{array} \right. \\
&= \left(30, 31\right)
\end{align*}
\]

The coefficient \( V_{61} \) does not depend on \( n \), the logarithmic contribution is thus proportional to the delta-function. To estimate the nonlogarithmic contribution in \[22\], we use the approximate electronic wave function \[\psi_e(r_e) \approx N|\psi_{1s}(r_1) + \psi_{1s}(r_2)|\], where \( \psi_{1s} \) is the ground state wave function of the hydrogen atom. The coefficient \( V_{60} \) for the 1S-state is equal to \(-0.63357\).

In fact, the latter term should be calculated numerically for the three-body case. But the contribution itself is of order 1 kHz and this simple approximation provides a good estimate.

2. The Wichman-Kroll contribution \[32\]:

\[ \Delta E_{WK}^{(7)} = \frac{\alpha^5}{\pi} W_{60} \langle V_6 \rangle \approx -0.1 \text{ kHz}. \]  

Here \( W_{60}(nS) = \frac{19}{45} - \frac{n^2}{27} \).

![Graph showing the coefficients \( A_{61}(R) \) and \( A_{60}(R) \) for the ground (1s\(\sigma\)) electronic state of the two-center problem (\( Z_1 = 2, Z_2 = -1, \) He\(^+\)\(\rho \) case) as a function of a bond length \( R \).]
For the hydrogen molecular ion fundamental transition like Coulomb sources.

bound electron in an arbitrary configuration of few point-perturbation with two one-loop self-energy operators

\( B_{\phi} \) and \( r \) order in the nonrecoil limit.

expansion for the electronic wave function is used: of yet uncalculated terms in the

\( \exp \rangle \) ≈ −1 kHz. (25)

The above is the complete set of contributions at \( m6 \) order in the nonrecoil limit.

In the next order \( (m6) \) we evaluate only the leading \( \ln^3(Z\alpha)^{-2} \) contribution. It represents the second order perturbation with two one-loop self-energy operators \( (m6) \) \( (Z\alpha)^6 \) 37:

\[ \Delta E_{2\text{loop}}^{(6)} = \frac{\alpha^5}{\pi^2} \left[ 0.42 \langle Z_1^2 \delta(r_1) + Z_2^2 \delta(r_2) \rangle \right] \approx 60 \text{ Hz.} \] (26)

Using its value we determine the theoretical uncertainty of yet uncalculated terms in the \( m6 \) order and higher.

\section{V. Numerical Results}

The numerical approach to the two-center problem has been already described in [22] [28]; briefly, the following expansion for the electronic wave function is used:

\[ \Psi_m(r_1, r_2) = e^{im\varphi \cdot r} e^{\sum_{i=1}^{\infty} C_i e^{-\alpha_i r_1 - \beta_i r_2}}, \] (27)

where \( (+) \) is used to get a \( gerade \) electronic state and \( (−) \) is for an \( ungerade \) state, respectively. Parameters \( \alpha_i \) and \( \beta_i \) are generated in a quasi-random manner.

We calculated mean values for all operators appearing in Eq. (20) for the ground \((1s)\) electronic state of the two-center problem, both for \( Z_1 = Z_2 = 1 \) (\( \text{H}_2^+ \) and \( \text{HD}^+ \) case) and \( Z_1 = 2, Z_2 = −1 \) for the antiprotonic helium. In this way we obtain the coefficients \( A_{50} \) and \( A_{61} \) (see Fig. 1 and 2) as well as the other contributions given in Sec. IV B. in the form of effective electronic potential curves.

We then averaged these electronic curves over vibrational wave functions in order to obtain energy corrections for individual states. Adding these new results to previously calculated contributions [2] [4], one obtains precise theoretical predictions for the frequencies of experimentally relevant transitions (see Tables I and II). Nonrelativistic energies and leading order corrections were obtained with the CODATA10 [15] recommended values. It is necessary to note that we used improved calculations for the leading order relativistic corrections \( (m6) \) and newly obtained values for the Bethe logarithm \( 38 \), which were the major source of inaccuracy in the leading order radiative corrections \( (m6) \). That allowed to significantly reduce numerical uncertainties in the contributions at these orders.

In the \( m6 \) order the uncertainty on the contribution stems from numerical uncertainty in calculation of the relativistic Bethe logarithm [22]. The recoil terms are already negligible at order \( \alpha^6(M/m) \), where they contribute about 300 Hz to the fundamental transitions of the hydrogen molecular ion.

The contribution from the finite charge distributions of nuclei deserves special discussion. For the fundamental transition in the \( \text{H}_2^+ \) ion the CODATA10 uncertainty results in 250 Hz uncertainty for the transition energy. If we use instead the charge radius from the muonic hydrogen measurements [10], the frequency will move by 3 kHz; ro-vibrational spectroscopy of \( \text{H}_2^+ \) is thus sensitive to the discrepancy between determinations of the proton radius. The CODATA10 uncertainty due to the deuteron rms charge radius for the \( \text{HD}^+ \) fundamental transition is 215 Hz and is so far negligible. In the antiprotonic helium the value of the rms charge radius of the alpha particle is taken from [41] and results in a frequency uncertainty of 7 kHz, while the corresponding uncertainty from the antiprotonic helium is less than order of magnitude, the antiproton–electron interaction being repulsive.

At present most accurate experimental results are available for the \( \text{HD}^+ \) molecular ion and for the antiprotonic helium. In Table III we compare our new theoretical results with the best experimental ones. Agreement is excellent in all cases except for the \( v = 0 \rightarrow v = 1 \) transition in \( \text{HD}^+ \) where the discrepancy is 2.6 \( \delta_{\text{exp}} \).
The achieved accuracy already allows for improved determination of the proton- and antiproton-to-electron mass ratios \([13] \) and may still be improved further as discussed above. Particularly, as a first step we intend to improve the relativistic Bethe logarithm calculations using the above. Particularly, as a first step we intend to improve the three-body molecular type systems. The theoretical uncertainty has been improved by about one order of magnitude to reach a level of 0.03 ppb in molecular hydrogen ions (resp. 0.13 ppb in the antiprotonic helium).

TABLE III: Comparison with most accurate experimental results for vibrational transitions to \(10^{-11}\).

| \(n,L\) | \(v,L\) | Experiment | Theory |

Appendix A: Asymptotic expansion of \(P_{rc}^{(1)}(k)\), \(P_{rc}^{(2)}(k)\), and \(P_{eq}(k)\)

Here we present without proof the results for the asymptotic expansion of the functions defined in Eqs. (8)–(10), which appear in the integrand of (7). Of particular importance is the term of order \(1/k^2\), which contributes to the \(\alpha\delta \ln \alpha\) part of Eq. (17). It is finite and the \(\pi Z^3 \langle \delta(\mathbf{r}) \rangle\) “counterterm” is determined by the choice of regularization of the divergent operators. As in \([22]\) we separate \(P_{rc}^{(1)}(k)\) into two parts:

\[ P_{rc}^{(1a)}(k) = \left. \frac{1}{k} \langle \mathbf{p} (E_0 - H - k)^{-1} \left( H_B - \langle H_B \rangle \right) \rangle \langle E_0 - H - k \rangle^{-1} \mathbf{p} \right| \]

**A1a**

\[ P_{rc}^{(1b)}(k) = 2 \langle H_B Q (E_0 - H)^{-1} Q \mathbf{p} \rangle \langle E_0 - H - k \rangle^{-1} \mathbf{p} \right| \]

**A1b**

In the following expressions, the second line gives the numerical values of the asymptotic expansion coefficients for the 1S state of the hydrogen atom.

\[ P_{rc}^{(1a)}(k) = -\frac{\sqrt{2}}{k^{3/2}} \pi Z^2 \langle \delta(\mathbf{r}) \rangle + \frac{8 \ln 2 - 13}{2k^2} \pi Z^3 \langle \delta(\mathbf{r}) \rangle + \frac{1}{16k^2} \langle (\nabla^4 V) \rangle_{\text{fin}} - \frac{1}{k^2} \langle (H_B - \langle H_B \rangle) \nabla^2 \rangle_{\text{fin}} + \ldots \]

**A2**

\[ P_{rc}^{(1b)}(k) = \frac{2}{k} \langle H_B - \langle H_B \rangle \rangle (E_0 - H)^{-1} \nabla^2 \rangle + \frac{2\sqrt{2}}{k^{3/2}} \pi Z^2 \langle \delta(\mathbf{r}) \rangle + \frac{\ln k}{k^2} \pi Z^3 \langle \delta(\mathbf{r}) \rangle + \frac{5 \ln 2 - 1}{2k^2} \pi Z^3 \langle \delta(\mathbf{r}) \rangle \]

\[ \langle H_B - \langle H_B \rangle \rangle (E_0 - H)^{-1} \nabla^2 \rangle_{\text{fin}} + \frac{1}{k^2} \langle (H_B - \langle H_B \rangle) \nabla^2 \rangle_{\text{fin}} + \ldots \]

**A3**
\[ P^{(2)}_{nc}(k) = \frac{1}{k} \left( \frac{8}{k^3} \right) \pi Z^2 \left( \langle \delta(r) \rangle - \langle \nabla^2 V \rangle \right) + \frac{4 \ln k}{k^2} \pi Z^3 \left( \langle \delta(r) \rangle - \langle \nabla^2 V \rangle \right) \]
\[ - \frac{12 \ln 2 + 4 \pi Z^3 \langle \delta(r) \rangle - \frac{1}{2k^2} \langle (\nabla^2 V) p^2 \rangle_{\text{fin}} - \frac{1}{k^2} \langle (\nabla^2 V)^2 \rangle_{\text{fin}} + \ldots \] (A4)
\[ = \frac{5}{k} \left( \frac{8}{k^3} + \frac{4 \ln k}{k^2} \right) - \frac{20 \ln 2 - 18}{k^2} + \ldots \]

\[ P_{nq}(k) = -\frac{1}{2} \left( \frac{8}{k^3} \right) \pi Z^2 \left( \langle \delta(r) \rangle - \langle \nabla^2 V \rangle \right) + \frac{40 \ln 2 + 76}{k^2} \pi Z^3 \left( \langle \delta(r) \rangle - \langle \nabla^2 V \rangle \right) \]
\[ + \frac{2}{k^2} \langle (\nabla^2 V)^2 \rangle_{\text{fin}} + \frac{3}{40k^2} \langle (\nabla^4 V) \rangle_{\text{fin}} + \frac{1}{k^2} \langle (\nabla^2 V)^2 \rangle_{\text{fin}} \] (A5)
\[ = \frac{1}{2} - \frac{3}{k} + \frac{8}{k^3} \frac{8 \ln k}{k^2} + \frac{24 \ln 2 - 10}{k^2} + \ldots \]

The sum of these terms makes up the result given in Eq. (11).

It is worth noting here that this is the main point where we differ from the approach used in [18], where the formal expansion over 1/k has been used:

\[ \frac{1}{E_0 - H - k} = -\frac{1}{k} \frac{E_0 - H}{k^2} - \frac{(E_0 - H)^2}{k^3} + \ldots, \] (A6)

which gives divergent matrix elements for individual S states in the hydrogen-like atom, but still the "normalized difference" \( \Delta_n \) is finite. This formalism is enough to get a complete result for arbitrary states in the hydrogen atom [see Eq. (3.43) and Table 1 of Ref. [18]], but not suitable for our generalization. So we took another way, which is to derive an appropriate approximation to the \( \psi_1 \) function

\[ \psi_1 = (E_0 - H - k)^{-1} ip \psi_0, \] (A7)

where \( \psi_0 \) is a stationary solution of the Schrödinger equation. \( \psi_1 \) is a regular function at small r thus providing finite expectation values for the operators appearing at 1/k^2 order. This procedure is very similar to what was used to obtain the asymptotic expansion for the nonrelativistic Bethe logarithm in [39].
