Introduction: Public Mental Health Services in Lombardy (Italy) has 27 Departments for Mental Health and Addictio Services and a number of private residential facilities. With the reorganization of the entire Healthcare system to deal with COVID-19, Regional Health Authorities recognized mental health as a priority and authorized the continuation of mental health services for the general population.

Objectives: To review the initiatives and procedures implemented in Lombardy during the Covid-19 pandemic in relation to the organization of Psychiatric Services and continuity of psychopharmacological treatment.

Results: Hospital admissions for acute psychiatric disorders in patients positive for COVID-19 required a dedicated area in the psychiatric ward or alternatively, a medical ward supported by psychiatric staff. Psychiatric hospital activity for patients negative for Covid-19 has been maintained as usual. The activity in the Mental Health Centers has been maintained in patients suffering from severe mental disorders as well as in those with serious medical problems or judicial sentences. Particular attention was paid to patients’ clinical monitoring and drug administration. Long-acting injection antipsychotics were often preferred to oral treatment to ensure adherence and continuity of care. Appropriate e-health technologies were used to reach patients and their families, for monitoring patients and avoiding drop-outs of patients with serious diseases.

Conclusions: Maintaining continuous monitoring of patients in contact with mental health services is essential for a careful assessment of their condition from both a psychopathological and medical point of view during pandemic.

Disclosure: No significant relationships.

There is little data on infection treatment in patients with mental disorders, including on the selection of psychotropic, antibiotic, antifungal, and antiviral medications. Bacterial, viral, and fungal infections often occur in patients with mental illnesses, and there is little data on rational pharmacotherapy in this vulnerable population. Antibiotic treatment is a common event during hospitalization in adult psychiatric hospitals and poses a risk of significant potential to almost a quarter of all patients. Most infections are bacterial infections where antibiotics are used, and this topic will be covered in this lecture.

Most patients being treated for urinary tract infections or respiratory tract infections. The most commonly prescribed antibiotics are co-amoxiclav and cotrimoxazole, followed by ciprofloxacin and nitrofurantoin. Drug-drug interactions (DDIs) between antibiotics and psychotropics are common events, where medications with QTc prolongation potential should be avoided (e.g., some
