HYPERBOLIC POLYNOMIALS AND
THE DIRICHLET PROBLEM

F. Reese Harvey and H. Blaine Lawson, Jr.*

ABSTRACT

This paper presents a simple, self-contained account of Gårding’s theory of hyperbolic polynomials, including a recent convexity result of Bauschke-Güler-Lewis-Sendov and an inequality of Gurvits. This account also contains new results, such as the existence of a real analytic arrangement of the eigenvalue functions.

In a second, independent part of the paper, the relationship of Gårding’s theory to the authors’ recent work on the Dirichlet problem for fully nonlinear partial differential equations is investigated. Each Gårding polynomial $p$ of degree $m$ on $\text{Sym}^2(\mathbb{R}^n)$ (hyperbolic with respect to the identity) has an associated eigenvalue map $\lambda : \text{Sym}^2(\mathbb{R}^n) \rightarrow \mathbb{R}^m$, defined modulo the permutation group acting on $\mathbb{R}^m$. Consequently, each closed symmetric set $E \subset \mathbb{R}^m$ induces a second-order p.d.e. by requiring, for a $C^2$-function $u$ in $n$-variables, that

$$\lambda((D^2u)(x)) \in \partial E \text{ for all } x.$$

Assume that $A \geq 0 \Rightarrow \lambda(A) \geq 0$ and that $E + \mathbb{R}^m \subset E$. A main result is that for smooth domains $\Omega \subset \mathbb{R}^n$ whose boundary is suitably $(p,E)$-pseudo-convex, the Dirichlet problem has a unique continuous solution for all continuous boundary data. This applies in particular to each of the $m$ distinct branches of the equation $p(D^2u) = 0$

In the authors’ recent extension of results from euclidean domains to domains in riemannian manifolds, a new global ingredient, called a monotonicity subequation, was introduced. It is shown in this paper that for every polynomial $p$ as above, the associated Gårding cone is a monotonicity cone for all branches of the the equation $p(\text{Hess } u) = 0$ where $\text{Hess } u$ denotes the riemannian Hessian of $u$.

1. Introduction

This paper is concerned with the Gårding theory of hyperbolic polynomials and its relation to the Dirichlet problem for fully nonlinear partial differential equations.

We recall that a homogeneous polynomial of degree \( m \) on a finite dimensional real vector space \( V \) is called hyperbolic with respect to a direction \( a \in V \) if (we assume \( p(a) > 0 \)) the one-variable polynomial \( t \mapsto p(ta + x) \) has \( m \) real roots for each \( x \in V \). Thus we can write

\[
p(ta + x) = p(a) \prod_{k=1}^{m} (t + \lambda_k(x)). \tag{1.1}
\]

The functions \( \lambda_k(x) \), called the \( a \)-eigenvalues of \( x \), are well defined up to permutation. In 1959 Gårding developed a beautiful theory of these hyperbolic polynomials [G2]. An important part of the theory concerned the set

\[
\Gamma \equiv \{ x \in V : \lambda_k(x) > 0, \text{ for all } k \} \tag{1.2}
\]

which is proved to be a convex cone. Of crucial importance for the paper is the monotonicity property: that if one orders the eigenvalues \( \lambda_1(x) \leq \cdots \leq \lambda_m(x) \), then

\[
\lambda_k(x + b) > \lambda_k(x) \quad \text{for all } b \in \Gamma, x \in V. \tag{1.3}
\]

Gårding’s motivation came from the theory of hyperbolic partial differential equations [G1]. (See also [H].) However, in subsequent years his results have attracted attention and found application in other areas. For example, Gårding theory was used to initiate hyperbolic programming by Guler [Gu]. (See also [R].)

This paper has two distinct and essentially independent objectives.

The first is to present a simple, self-contained account of Gårding’s theory. Our account starts with a new result, Theorem 2.9 below, which states that

For \( b \in \Gamma \) and \( x \in V \) the \( a \)-eigenvalues can be arranged so that each of the functions \( t \mapsto \lambda_k(x + tb) \) is a strictly increasing real-analytic mapping from \( \mathbb{R} \) onto \( \mathbb{R} \) with real analytic inverse \( s \mapsto -\mu_k(x - sa) \) where \( \mu_k \) is a \( b \)-eigenvalue.

The proof of this result uses only the classical elementary fact that each point on an algebraic curve admits a local uniformizing parameter. Gårding’s theory, together with a recent convexity result of Bauschke, Güler, Lewis and Sendov [BGLS], is then presented as a series of elementary consequences of this theorem. This is done in Sections 2 and 3. Another recent result, due to Gurvits [Gur1,2], is presented in Appendix B as an improvement of a basic inequality of Gårding. The parallels in the proofs are emphasized.

Historical Note: In 1958 P. Lax [L] conjectured that for homogeneous polynomials \( p(x, y, z) \) in three variables which are hyperbolic with respect to a direction \( a \), say \( a = (0, 0, 1) \), there exist symmetric matrices \( A, B \) such that \( p(x, y, z) = \det(xA + yB + zI) \). This conjecture was essentially established by Vinnikov [V] in 1993 (see [LPR]). Armed with this highly non-trivial result, one can quickly establish the full Gårding theory,
since all arguments only involve three variables at a time. However, the presentation here emphasizes quite elementary proofs.

The second objective of this paper is to investigate the relationship of Gårding theory to the theory of fully nonlinear second-order (degenerate elliptic) equations, first discussed by Caffarelli, Nirenberg and Spruck [CNS] for $O_n$-invariant equations. This discussion can be easily ignored by readers interested only in the first part of the paper on Gårding theory. Here the basic vector space in question is the space $V = \text{Sym}^2(\mathbb{R}^n)$ of real symmetric $n \times n$ matrices. This is because a second-order equation can be viewed as a subset $F \subset \text{Sym}^2(\mathbb{R}^n)$. The solutions or $F$-harmonic functions are functions $u$ satisfying (at least in the $C^2$-case)

$$(D^2u)(x) \in \partial F.$$ 

In [HL1] the Dirichlet problem is studied and solved via the Perron method utilizing the notion of an $F$-subharmonic function. The only condition the closed subset $F$ must satisfy in this theory is the positivity condition

$$F + P \subset F \quad \text{for each} \quad P > 0 \quad \text{(positive definite).} \quad (1.4)$$

In this case the closed set $F \subset \text{Sym}^2(\mathbb{R}^n)$ is referred to as a subequation. One of the main points of this paper is to show how Gårding’s theory determines a vast array of interesting and natural subequations. His monotonicity result (1.3) is exactly what is needed to establish the crucial positivity condition (1.4).

The first and most basic example is $F = \Gamma$, the Gårding cone itself. Here the positivity condition (1.4) must be assumed, not deduced. However, requiring (1.4) is equivalent to requiring that the polynomial $p$ be hyperbolic in each positive definite direction $P > 0$ in $\text{Sym}^2(\mathbb{R}^n)$. These polynomials will be called Dirichlet-Gårding polynomials for the purposes of this paper.

The main new construction of subequations in this paper can be described as follows. Suppose that $p$ is a Dirichlet-Gårding polynomial of degree $m$, and choose a hyperbolic direction $a \in \Gamma$, for example any $P > 0$ or, more specifically, the identity $I \in \text{Sym}^2(\mathbb{R}^n)$. Then the eigenvalue map $\lambda : \text{Sym}^2(\mathbb{R}^n) \to \mathbb{R}^m$ is defined, as above, modulo coordinate permutations on $\mathbb{R}^m$. Consequently each closed symmetric subset $E \subset \mathbb{R}^m$ determines a second-order partial differential equation (at least for $C^2$-functions $u$) by requiring

$$\lambda ((D^2u)(x)) \in \partial E. \quad (1.5)$$

One main result (Theorem 5.19) says that if a closed symmetric subset $E \subset \mathbb{R}^m$ satisfies the universal positivity condition:

$$E + \lambda \subset E \quad \text{for all} \quad \lambda \in \mathbb{R}^m \quad \text{with} \quad \lambda > 0 \quad \text{(i.e., each} \quad \lambda_k > 0), \quad (1.6)$$

then the subset $F_E$ of $\text{Sym}^2(\mathbb{R}^n)$ defined by

$$F_E \equiv \{ A \in \text{Sym}^2(\mathbb{R}^n) : \lambda(A) \in E \} \quad (1.7)$$
is a subequation, that is, \( F_\mathcal{E} \) satisfies the positivity condition (1.4). The closed sub-
sets \( \mathcal{E} \) satisfying (1.6) can be regarded as universal subequations on \( \mathbb{R}^m \) since they
induce a subequation on \( \mathbb{R}^n \) for each Dirichlet-Gårding polynomial of degree \( m \) on
\( \text{Sym}^2(\mathbb{R}^n) \) (and each hyperbolic direction). For each such subequation on \( \mathbb{R}^n \), The-
orem 5.20 concludes that the Dirichlet problem has a unique continuous solution for all continuous
boundary functions on any smooth domain \( \Omega \) in \( \mathbb{R}^n \) whose boundary is suitably “pseudo”-convex.

This applies in particular to each of the branches of the equation

\[
p((D^2 u) = 0,
\]

where the \textit{kth branch} \( F_k \) is defined by requiring that

\[
\lambda_k^\uparrow(D^2 u) \geq 0
\]

where \( \lambda_k^\uparrow \) is the \( k \)th ordered eigenvalue function of \( p \). These branches \( F_k \) are independent
of the choice of hyperbolic direction (Theorem 2.12). The universal \( k \)th branch \( E_k \subset \mathbb{R}^m \) is defined by

\[
E_k \equiv \{ \lambda \in \mathbb{R}^m : \text{at least } m - k + 1 \text{ of the } \lambda_j \text{ are } \geq 0 \} = \{ \lambda \in \mathbb{R}^m : \lambda_k^\uparrow \geq 0 \}
\]

In Appendix A we give an algebraic description of each of these branches in terms of polynomial inequalities.

We shall return to a discussion of examples of universal eigenvalue subequations \( \mathcal{E} \subset \mathbb{R}^m \), but first we present examples of Dirichlet-Gårding polynomials. Three basic
irreducible classical examples are the three determinants: \( \det_\mathbb{R} \) on \( \text{Sym}^2(\mathbb{R}^n) \), \( \det_\mathbb{C} \)
on \( \text{Sym}^2(\mathbb{R}^{2n}) \) and \( \det_\mathbb{H} \) on \( \text{Sym}^2(\mathbb{R}^{4n}) \). They are discussed in Section 5. A new
irreducible example of degree \( 2^n \) on \( \text{Sym}^2(\mathbb{R}^{2n}) \), which yields a notion of Lagrangian
harmonicity, is also discussed there. Our theory enables us to treat all branches of this
new equation even though an explicit rendering of them is quite complicated.

Several methods of constructing new Dirichlet-Gårding polynomials from a given
Dirichlet-Gårding polynomial are outlined in Section 5 as well. One method is to take a
directional derivative in one of the directions in the Gårding cone. Equivalently, these
polynomials are the elementary symmetric functions in the eigenvalue functions. A
second method constructs a Dirichlet-Gårding polynomial whose eigenvalue functions
are the \( \binom{m}{p} \) possible \( p \)-fold sums of the given eigenvalue functions. A third method
constructs (for each \( \delta > 0 \)) a new Dirichlet-Gårding polynomial (of the same degree)
whose open Gårding cone is uniformly elliptic, i.e., contains the closed set of all \( A \geq 0 \)
in \( \text{Sym}^2(\mathbb{R}^n) \). Since implementing these methods is not a commutative process, taken
together they yield a huge collection of Dirichlet-Gårding polynomials.

The second and third methods are special cases of a more general method. If \( Q \) is a symmetric polynomial on \( \mathbb{R}^m \) of degree \( N \) which is hyperbolic in all directions
\( \lambda > 0 \), and \( p \) is a Dirichlet-Gårding polynomial on \( \text{Sym}^2(\mathbb{R}^n) \), then \( q(A) = Q(\lambda(A)) \) is
a Dirichlet-Gårding polynomial of degree \( N \) on \( \text{Sym}^2(\mathbb{R}^n) \).

Now we return to the other ingredient, the universal subequations \( \mathcal{E} \). A classifica-
tion or “structure” theorem is given in Proposition 5.25 in terms of Lipschitz graphs.
However, there are examples which are obscured by this structure theorem, such as the universal Special Lagrangian subequation $E_c \subset \mathbb{R}^m$ defined by requiring that
\[
\sum_{k=1}^m \arctan \lambda_k \geq c.
\]
The structure theorem says that every universal subequation $E$ has boundary which is a graph
\[
\partial E = \{ f(\lambda)e + \lambda : \lambda \cdot e = 0 \}
\]
over the hyperplane \( \{e \cdot \lambda = 0\} \) where \( e = (1, ..., 1) \). $E$ is then the region above the graph in this picture. The graphing function $f$ must be Lipschitz with Lipschitz constant one using a natural norm on $\{ e \cdot \lambda = 0 \}$.

The Dirichlet problem is solved in Theorem 5.20 without assuming that the subequation $F_E$ defined by (1.7) is either convex or uniformly elliptic, but our construction includes many such examples because, if $E$ is convex, then $F_E$ is convex, and if $E$ is uniformly elliptic, then so is $F_E$ (see Theorem 5.19 (a) and (b)).

The general Gärding theory has an important application to the analogous Dirichlet problem on Riemannian manifolds. In a recent paper [HL2] the authors have carried over the basic results of [HL1] from constant coefficient purely second-order subequations to equations defined in a quite general setting on Riemannian manifolds, and manifolds with reduced structure group – such as almost complex Hermitian manifolds. A fundamental new feature of this theory is the introduction of a monotonicity cone $M_F$ for a given subequation $F$. Existence and uniqueness results are established under the (essentially necessary) hypothesis that there exist some strictly $M_F$-subharmonic function defined on a neighborhood of the domain in question. The Gärding monotonicity result (1.3) exactly provides such monotonicity cones. For a given $I$-hyperbolic polynomial $p$ on $\text{Sym}^2(\mathbb{R}^n)$ the Gärding cone $\Gamma$ is a monotonicity cone for each branch of the equation $\{ p(D^2u) = 0 \}$. More generally, the subequations $F_E$ on $\mathbb{R}^n$, determined by $p$ of degree $m$ and a universal subequation $E$ on $\mathbb{R}^m$, are not confined to domains in $\mathbb{R}^n$, but extend to all parallelizable Riemannian $n$-manifolds, and when $p$ has a non-trivial invariance group $G$, they extend to all Riemannian $n$-manifolds with structure group reduced (topologically) to $G$. Details are discussed in Chapter 6.
2. Gårding’s Theory of Hyperbolic Polynomials

This section gives an essentially self-contained account of the Gårding theory of hyperbolic polynomials. Some aspects of the presentation are new – for example Theorem 2.7. Its proof relies only on the classical elementary fact that each point on an algebraic curve admits local uniformizing parameters (cf. (2.12)). This Theorem 2.7 together with Remark 2.3 imply all the basic results in \([G_2]\).

Preliminaries

Suppose that \(p\) is a homogeneous polynomial of degree \(m\) on a complex vector space \(V_\mathbb{C}\). Given points \(a, x \in V_\mathbb{C}\) with \(p(a) \neq 0\), the one-variable polynomial \(s \mapsto p(sa + x)\) factors as

\[
p(sa + x) = p(a) \prod_{k=1}^{m} (s + \lambda_k(x)) \quad \text{and} \quad p(x) = p(a) \prod_{k=1}^{m} \lambda_k(x), \tag{2.1}
\]

where, by definition, \(\lambda_1(x), \ldots, \lambda_m(x)\) are the \(a\)-eigenvalues of \(x\) and \(r_k(x) \equiv -\lambda_k(x)\) are the \(a\)-roots of \(x\). Of course \(\lambda(x) \equiv (\lambda_1(x), \ldots, \lambda_m(x))\) is defined only modulo the permutation group \(\pi_m\). When necessary, the dependence of the eigenvalues of \(a\) on the choice of \(a\) will be denoted by \(\lambda_a^k(x) \equiv \lambda_k(x)\) and \(\lambda_a(x) = (\lambda_a^1(x), \ldots, \lambda_a^m(x))\), and similarly for the \(a\)-roots of \(x\).

Everything proven in this section uses one or more of the elementary properties discussed next – and very little else.

**Elementary Properties:** Suppose \(p(a) \neq 0\). It follows easily from (2.1) that for all \(t \in \mathbb{C}\) and \(x \in V_\mathbb{C}\):

1. \(\lambda_a^k(tx) = t\lambda_a^k(x) \mod \pi_m\),
2. \(\lambda_a^k(ta + x) = t + \lambda_a^k(x) \mod \pi_m\), and so (2a) \(\lambda_a^k(a) = 1\) for all \(k\).

Sometimes it is convenient to set \(e = (1, \ldots, 1)\) and restate (2) in the form

\[
(2)’ \quad \lambda_a(ta + x) = te + \lambda_a(x) \mod \pi_m.
\]

Using (2.1) with \(x = tb, t \in \mathbb{C}, b \in V_\mathbb{C}\) and applying (1) yields

\[
p(sa + tb) = p(a) \prod_{k=1}^{m} (s + t\lambda_k(b)) \quad \tag{2.1}’
\]

Note that (2.1)’ gives an explicit factorization of \(p\) restricted to \(\text{span} \{a, b\}\). This will be useful in establishing certain important properties.

We shall use the notation

\[
p_x’(y) \equiv \frac{d}{dt} p(y + tx)_{|t=0}
\]
for the directional derivative of $p$ at $y$ in the direction $x$. Setting $s = 1$ in (2.1)$'$ and then taking the logarithmic derivative at $t = 0$ proves that

$$(3) \quad p(a + tx) = p(a) \prod_{k=1}^{r} (1 + t\lambda_{a}^{k}(x)) \quad \text{and} \quad \frac{p'(a)}{p(a)} = \sum_{k=1}^{r} \lambda_{a}^{k}(x).$$

Here $r = r(x)$, called the rank of $x$, is the number of non-zero $a$-eigenvalues, which are here listed first. The nullity of $x$ is the number $n(x) = m - r(x)$ of $a$-eigenvalues which are zero. The elementary formula (3) is particularly useful for studying degenerate cases where the rank of $x$ is less than $m$, i.e., where $p(x) = 0$.

As a consequence of the second part of Property (3) we have

$$(4) \quad \text{The } a\text{-trace of } x, \text{ trace}_{a}(x) = \sum_{k=1}^{r} \lambda_{a}^{k}(x) \text{ is a linear functional in } x.$$  

A property, not used here and left as an exercise, is that for $b \in V_{\mathbb{C}}$ with $p(b) \neq 0$,

$$\lambda_{a}^{k}(a) = \frac{1}{\lambda_{a}^{k}(b)} \mod \pi_{m}.$$  

The standard algebraic fact that the roots of a polynomial depend continuously on the coefficients (if the degree does not drop) will be used in several guises. For instance,

$$(5) \quad \text{The } \lambda_{a}^{k}(x) \mod \pi_{m} \text{ are continuous in } x \in V_{\mathbb{C}}.$$  

Hyperbolic Polynomials

Now suppose that $p$ is a homogeneous real polynomial of degree $m$ on a real vector space $V$.

**Definition 2.1.** Given $a \in V$, the polynomial $p$ is $a$-hyperbolic if $p(a) > 0$ and the eigenvalues $\lambda_{k}(x)$, $k = 1, \ldots, m$ are real for all $x \in V$. That is, the polynomial $t \mapsto p(ta + x)$ has exactly $m$ real roots for each $x \in V$. The Gårding cone $\Gamma \subset V$ (also denoted by $\Gamma_{a}$) is defined to be the set of $x$ such that $\lambda_{k}(x) > 0$ for $k = 1, \ldots, m$.

Of course, the elementary properties (1) through (5) hold for $p$ on $V$.

A Basic Inequality

Here we prove an elementary version of Gårding’s inequality.

**Lemma 2.2.** Suppose $p$ is $a$-hyperbolic of degree $m$. If $x \in \Gamma_{a}$, then

$$\left( \frac{p(x)}{p(a)} \right)^{\frac{1}{m}} \leq \frac{1}{m} \frac{p'(a)}{p(a)}, \quad \text{with equality } \iff \lambda_{1}(x) = \cdots = \lambda_{m}(x) \quad (2.2)$$

**Proof.** Each of the $a$-eigenvalues $\lambda_{k}$ of $x$ is $> 0$. Using the second part of (2.1) and of property (3), one sees that (2.2) is the classical inequality between the geometric and the arithmetic mean:

$$\left( \prod_{k=1}^{m} \lambda_{k} \right)^{\frac{1}{m}} \leq \frac{1}{m} \sum_{k=1}^{m} \lambda_{k}, \quad \text{with equality } \iff \lambda_{1}(x) = \cdots = \lambda_{m}(x) \quad (2.2)'$$
Remark 2.3. The inequality (2.2) has a geometric formulation. The condition that the graph of a function \( f(x) \) lies below its tangent plane at a point \((a, f(a))\) can be written as:

\[
    f(x) \leq f(a) + f'_x(a) = f(a) - f'_a(a) + f'_x(a) \quad \text{for } x \text{ near } a. \quad (2.3)
\]

If \( f \) is homogeneous of degree one, recall that \( f'_a(a) = f(a) \), so that condition (2.3) simplifies to

\[
    f(x) \leq f'_x(a) \quad \text{for } x \text{ near } a. \quad (2.3')
\]

Take \( f(x) = p(x)^{\frac{1}{m}} \) with \( x \in \Gamma_a \). Then \( f'_x(a) = \frac{1}{m} p(a)^{\frac{1}{m} - 1} p'_x(a) \) and we see that (2.3)' and (2.2) are the same inequality. This proves that

\[
    \text{If } p \text{ is } b \text{ hyperbolic for all } b \in \Gamma_a, \text{ then } p(x)^{\frac{1}{m}} \text{ is a concave function on } \Gamma_a. \quad (2.4)
\]

In particular, in this case \( \Gamma_a \) is convex, since \(-p(x)^{\frac{1}{m}} \) is convex and negative on \( \Gamma_a \) with boundary values zero.

**Ordered Eigenvalues**

Suppose \( p \) is an \( a \)-hyperbolic polynomial. Given a vector \( \lambda \in \mathbb{R}^m \), let \( \lambda^\uparrow \in \mathbb{R}^m \) denote the non-decreasing reordering of \( \lambda \), i.e., \( \lambda^\uparrow_1 \leq \lambda^\uparrow_2 \leq \cdots \leq \lambda^\uparrow_m \). The **ordered eigenvalue functions** are then defined to be \( \lambda^\uparrow(x) = (\lambda^\uparrow_1(x), \ldots, \lambda^\uparrow_m(x)) \). Note that \( \lambda_{\min}(x) = \lambda^\uparrow_1(x) \) and \( \lambda_{\max}(x) = \lambda^\uparrow_m(x) \). It is useful to rewrite some of the properties listed above in terms of the ordered \( a \)-eigenvalues.

**Elementary Properties:** For each \( k = 1, \ldots, m \), we have

1. \( \lambda^\uparrow_k(tx) = t\lambda^\uparrow_k(x) \), for \( t \geq 0 \),
2. \( \lambda^\uparrow_k(-x) = -\lambda^\uparrow_{m-k+1}(x) \), and in particular, \( \lambda_{\max}(x) = -\lambda_{\min}(-x) \)
3. \( \lambda^\uparrow_k(ta + x) = t + \lambda^\uparrow_k(x) \) for all \( t \in \mathbb{R} \),
4. \( \lambda^\uparrow_k(x) \) is continuous.

**Definition 2.4.** The sets

\[
    F_k \equiv \{ \lambda^\uparrow_k \geq 0 \}
\]

(rather than \( \partial F_k \)) will be referred to as the **branches** of \( \{ p = 0 \} \). The **principal** or **smallest branch** \( F_1 = \{ \lambda_{\min} \geq 0 \} \) is of particular interest.

Note that each branch \( F_k \) is a cone with vertex at the origin by (1a).

**Remark 2.5.** Given a continuous function \( g : \mathbb{R}^{N-1} \rightarrow \mathbb{R} \), we define the **associated graphing function** \( G : \mathbb{R}^N \rightarrow \mathbb{R} \) by \( G(t, x) = t - g(x) \). The closed set \( F \equiv \{ G \geq 0 \} \)
above the graph of \( g \) has interior \( \text{Int} F = \{ G > 0 \} \) and boundary \( \partial F = \{ G = 0 \} \) equal to the graph of \( g \). Moreover, \( \text{Int} F \) is a connected open set with \( F = \overline{\text{Int} F} \). Finally note:

\[
F \text{ is convex} \iff g \text{ is convex} \iff G \text{ is concave} \quad (2.5)
\]

These obvious facts can be applied as follows. Suppose that \( p \) is an \( a \)-hyperbolic polynomial and consider the ordered eigenvalues. Take \( \mathbb{R}^{N-1} \) to be a hyperplane \( W \subset V \) transverse to \( a \).

If \( g \) is the restriction of \(-\lambda^\uparrow_k \) to \( W \), then \( G = \lambda^\uparrow_k \) since for \( x \in W \), we have \( G(ta + x) = t - g(x) = t + \lambda^\uparrow_k(x) = \lambda^\uparrow_k(ta + x) \) where the last equality follows from Property (2). Consequently, as a special case of Remark 2.5 we have:

**Proposition 2.6.** Suppose that \( p \) is \( a \)-hyperbolic. Then \( \partial F_k = \{ \lambda^\uparrow_k = 0 \} \), and \( \text{Int} F_k = \{ \lambda^\uparrow_k > 0 \} \). Furthermore, \( \text{Int} F_k \) is a connected set satisfying \( F_k = \overline{\text{Int} F_k} \). In particular

\[
\Gamma = \text{Int} F_1, \quad F_1 = \overline{\Gamma}, \quad \text{and}
\]

\[
\Gamma \text{ is convex} \iff \lambda_{\min} \text{ is concave} \iff \lambda_{\max} \text{ is convex} \quad (2.6)
\]

Thus the Gårding cone is the interior of the principal branch. The last equivalence in (2.6) follows since \( \lambda_{\max}(x) = -\lambda_{\min}(-x) \) by (1b).

**Corollary 2.7.** The Gårding cone \( \Gamma_a \) is the connected component of \( \{ p \neq 0 \} \) which contains \( a \).

**Proof.** Let \( \Gamma \) denote the connected component of \( \{ p \neq 0 \} \) containing \( a \). By Property (2a) we have \( a \in \Gamma \), and since \( \Gamma \) is open and connected, \( \Gamma_a \subset \Gamma \). Since the \( a \)-eigenvalues \( \lambda_k(x) \) never vanish on \( \Gamma \) and equal 1 at \( a \in \Gamma \), they are strictly positive on \( \Gamma \), i.e., \( \Gamma \subset \Gamma_a \).

**Remark 2.8.** Setting \( k^* = m - k + 1 \), we have

\[
x \in \text{Int} F_k \iff x \text{ has at least } k^* \text{ strictly positive eigenvalues.}
\]

**A Real Analytic Arrangement of the Restricted Eigenvalues**

Throughout this subsection we assume that \( p \) is an \( a \)-hyperbolic polynomial of degree \( m \) on \( V \). The eigenvalues \( \lambda_1(x), ..., \lambda_m(x) \) of \( x \in V \) are well defined mod \( \pi_m \). The continuity of \( \lambda_k \) as a function of \( x \) (Property (5)) cannot be improved to differentiability. However, by restricting the \( \lambda_k \) to the line through \( x \) in a direction \( b \in \Gamma \), the one-variable functions \( \lambda_1(x + tb), ..., \lambda_m(x + tb) \), of \( t \) defined mod \( \pi_m \), can be arranged so that each function is a strictly increasing bi-real-analytic mapping of \( \mathbb{R} \) onto \( \mathbb{R} \). The functions

\[
\lambda_1(x - tb), ..., \lambda_m(x - tb)
\]
of $t$ defined mod $\pi_m$ will be referred to as the **restricted eigenvalue functions**.

**THEOREM 2.9.** Suppose that $p$ is an $a$-hyperbolic polynomial of degree $m$ on $V$ with Garding cone $\Gamma$. Then $p$ is also $b$-hyperbolic for each $b \in \Gamma$, and $\Gamma_b = \Gamma_a$. Moreover, for each fixed $x \in V$ the restricted eigenvalue functions of $t$

$$
\lambda^1_a(x - tb), \ldots, \lambda^m_a(x - tb)
$$

(2.7)
can be arranged so that each one is a real analytic, strictly decreasing function from $\mathbb{R}$ onto $\mathbb{R}$, and inverses are given by

$$
\lambda^1_b(x - sa), \ldots, \lambda^m_b(x - sa).
$$

(2.8)

Consequently,

$$
\frac{d}{dt} \lambda^k_a(x + tb) > 0 \text{ for all } t \in \mathbb{R} \text{ and } k = 1, \ldots, m.
$$

(2.9)

**Remark.** Note that by combining Corollary 2.7 and Theorem 2.9 we have that for each connected component $\Gamma$ of the set $\{p \neq 0\}$,

$$
p \text{ is } a\text{-hyperbolic for some } a \in \Gamma \iff p \text{ is } a\text{-hyperbolic for all } a \in \Gamma.
$$

Consequently it is reasonable to use the phrase “$p$ is $\Gamma$-hyperbolic” where $\Gamma$ is a connected component of $\{p \neq 0\}$.

Theorem 2.9 can be deduced from a local result, which holds without assuming $b \in \Gamma$.

**Lemma 2.10.** Suppose $x, b \in V$. Then near any point $t_0 \in \mathbb{R}$ the restricted root functions

$$
r^1_a(tb + x), \ldots, r^m_a(tb + x)
$$

(2.10)
can be arranged to be real-analytic in $t$. Therefore, by uniqueness of real analytic continuation the local arrangements (2.10) extend to a global arrangement of the restricted roots, which we label as

$$
s_k(t) = r^k_a(tb + x) \quad k = 1, \ldots, m.
$$

(2.11)

**Proof.** Let $s_1$, denote one of the root functions evaluated at $t_0$. That is, $(s_1, t_0)$ is a point on the complex algebraic curve

$$
C \equiv \{(s, t) : p(sa + tb + x) = 0\}
$$

in $\mathbb{C}^2$. Choose a local irreducible component $C_1$ of $C$ at $(s_1, t_0)$, along with a local uniformizing parameter $z$. This means that we have holomorphic functions

$$
s(z) = s_1 + z^p g(z) \quad \text{and} \quad t(z) = t_0 + z^q h(z), \text{ for } |z| < \delta,
$$

(2.12)
with \( g(0) \neq 0, h(0) \neq 0 \), such that \( z \mapsto (s(z), t(z)) \) is a homeomorphism of a neighborhood of \( 0 \in \mathbb{C} \) onto a neighborhood of \((s_1, t_0)\) in \( C_1 \). By extracting a \( q \)th root of \( h(z) \) we may assume that \( h(z) \equiv 1 \), i.e.,

\[
t(z) = t_0 + z^q.
\]

It will suffice to show that \( q = 1 \), for then \( s(z) \) is a root of \( p(sa + (t_0 + z)b + x) \), and, as such, must be real if \( z \) is real. Setting

\[
r_1^1(tb + x) \equiv s(t - t_0)
\]

we obtain a local real analytic restricted root function. Repeating this construction for each of the \( m \) real points \((s_1, t_0), \ldots, (s_n, t_0) \in C \) (counting multiplicities) will complete the proof.

We now show that \( q = 1 \). Since \( s(z) \) is a root of \( s \mapsto p(sa + t(z)b + x) \) and \( p \) is \( a \)-hyperbolic,

\[
z^q \text{ real } \implies s(z) \text{ real}. \tag{2.13}
\]

In particular, \( z \) real \( \implies s(z) \) real, so that the power series

\[
s(z) = \sum_{k=0}^{\infty} a_k z^k
\]

for \( s(z) \) has real coefficients \( a_k \). Set \( \omega \equiv e^{\frac{2\pi i}{q}} \) and \( z = r\omega \) with \( r \) real. Then \( \omega^k \) is not real unless \( k \) is a multiple of \( q \). Now \( z^q \) is real and hence \( \sum_{k=0}^{\infty} a_k \omega^k r^k \) is real by (2.13). It follows that \( a_k = 0 \) unless \( k \) is a multiple of \( q \). Thus \( s(z) = s_1 + \sum_{k=1}^{\infty} b_k z^k q = s_1 + f(z^q) \). Since \( z \mapsto (f(z^q), z^q)) = (s(z) - s_1, t(z) - t_0) \) is one-to-one, this proves that \( q = 1 \). \( \blacksquare \)

**Proof of Theorem 2.9.** Now we will use the fact that \( b \in \Gamma \). By Property (1)

\[
r_a^k(tb + x) = tr_a^k \left( b + \frac{x}{t} \right) \mod \pi_m \quad \text{for } t \neq 0. \tag{2.14}
\]

For \(|t| >> 0\) sufficiently large,

\[
r_a^k \left( b + \frac{x}{t} \right) < 0. \tag{2.15}
\]

This follows from the continuity of the eigenvalues (5) and the fact that \( r_a^k(b) < 0 \), i.e., \( b \in \Gamma \). Consequently,

\[
\lim_{t \to \pm \infty} r_a^k(tb + x) = \mp \infty. \tag{2.16}
\]

In particular, none of the functions \( s_k(t) \) are constant, and each maps onto all of \( \mathbb{R} \).

Suppose that \( \varphi(t) \) is one of the function \( s_k(t) \) which is repeated \( \ell \)-times. If \( s_0 \) is not a critical value of \( \varphi \), then

\[
each point \ t_j \in \varphi^{-1}(s_0) \ is a root of \ t \mapsto p(s_0a + tb + x) \ of multiplicity \ell. \tag{2.17}
\]
This follows from the fact that the functions \( s - \varphi(t) \) and \( t - \varphi^{-1}(s) \) vanish to first order on the same real curve in \( \mathbb{R}^2 \) near \((s_0, t_0)\) and therefore differ by a smooth (in fact, real analytic) factor \( \alpha(s, t) \) near \((s_0, t_0)\) with \( \alpha(s_0, t_0) \neq 0 \).

Let \( S_0 \) denote the set of points which are not critical values for any of the functions \( s_k(t) \). If \( s_0 \in S_0 \), then \( s_k^{-1}(s_0) \) can have at most one point \( t_k \). Otherwise by (2.17) the polynomial \( t \mapsto p(s_0a + tb + x) \) would have more than \( m \) roots. Hence each \( s_k \) is one-to-one outside its critical points. This is enough to conclude that each \( s_k \) is a homeomorphism from \( \mathbb{R} \) to \( \mathbb{R} \). Therefore, each \( s_k(t) \) defined by (2.11) is a strictly decreasing homeomorphism from \( \mathbb{R} \) onto \( \mathbb{R} \).

Moreover, for \( s_0 \in S_0 \) the points \( t_1 = s_1^{-1}(s_0), \ldots, t_m = s_m^{-1}(s_0) \), listed to multiplicity, provide \( m \) (real) roots of \( t \mapsto p(s_0a + tb + x) \). This proves that

\[
r_b^k(sa + x) = s_k^{-1}(s)
\]  

for \( s \in S_0 \). By continuity of the roots (2.18) remains true for critical values \( s \in \mathbb{R} \).

In particular, the roots

\[
r_b^1(x) = s_1^{-1}(0), \ldots, r_b^m(x) = s_m^{-1}(0)
\]

of \( p(tb + x) \) are all real, proving that the polynomial \( p \) is \( b \)-hyperbolic. By (2.16) the monotone functions \( s_k(t) = r_b^k(tb + x) \) must be non-increasing homeomorphisms of \( \mathbb{R} \) onto \( \mathbb{R} \). Since \( p \) is \( b \)-hyperbolic, the results established for \( r_a \) apply to \( r_b \). In particular, by (2.18) each of the inverses \( s_k^{-1} \) is real analytic. This proves that for some arrangement of the restricted roots

\[
s = r_a^k(x + tb) \quad \text{and} \quad t = r_b^k(x + ta) \quad k = 1, \ldots, m
\]

are inverses of each other. Also,

Each \( r_b^k(x + tb) \), as a function of \( t \), is a strictly decreasing bi-real-analytic map from \( \mathbb{R} \) onto \( \mathbb{R} \).

\[
(2.20)
\]

Finally note that (2.19) and (2.20) remain true with \( r_a^k(x + tb) \) replaced by \( \lambda_a^k(x - tb) = -r_a^k(x - tb), \quad k = 1, \ldots, m \).

\[
\boxdot
\]

**Example 2.11. (Comparing Real Analytic and Ordered Eigenvalues).** The polynomial \( p(x) = x_1^2 - x_2^2 - x_3^2 \) on \( \mathbb{R}^3 \) is the prototype of all hyperbolic polynomials. It is \((1, 0, 0)\)-hyperbolic with Gårding cone equal to the light cone \( \Gamma = \{p(x) > 0\} \cap \{x_1 > 0\} \).

The ordered eigenvalue functions are:

\[
\lambda_{\min}(x) = x_1 - \sqrt{x_2^2 + x_3^2} \leq x_1 + \sqrt{x_2^2 + x_3^2} = \lambda_{\max}(x).
\]

Choose \( b \in \Gamma \) of the form \( b_1 > b_2 > 0 = b_3 \). The ordered arrangement of the restricted eigenvalue functions is

\[
\lambda_{\min}(x + tb) = x_1 + tb_1 - \sqrt{(x_2 + tb_2)^2 + x_3^2}
\]

\[
\lambda_{\max}(x + tb) = x_1 + tb_1 + \sqrt{(x_2 + tb_2)^2 + x_3^2}
\]
If \( x_3 \neq 0 \), then both of these functions are real analytic in \( t \), and hence the real analytic arrangement agrees with the ordered arrangement. If \( x_3 = 0 \), the ordered arrangement is:

\[
\lambda_{\min}(x) = x_1 + t b_1 - |x_2 + t b_2| \leq x_1 + t b_1 + |x_2 + t b_2| = \lambda_{\max}(x + t b).
\]

while the real analytic arrangement is

\[
\lambda^1(x + t b) = x_1 + t b_1 - (x_2 + t b_2)
\]

\[
\lambda^2(x + t b) = x_1 + t b_1 + (x_2 + t b_2).
\]

It is interesting to note the following asymptotics:

for \( t \gg 0 \), \( \lambda_{\min}(x + t b) \sim t \lambda_{\min}(b) \) and \( \lambda_{\max}(x + t b) \sim t \lambda_{\max}(b) \)

while for \( t \ll 0 \), \( \lambda_{\min}(x + t b) \sim t \lambda_{\max}(b) \) and \( \lambda_{\max}(x + t b) \sim t \lambda_{\min}(b) \).

which shows that (2.14) only holds mod \( \pi m \).

Since the \( a \)-eigenvalues are all real, the rank of \( x \in V \) can be refined into the sum of the plus rank, denoted \( r^+(x) \), and the minus rank, denoted \( r^-(x) \).

**Theorem 2.12.** The quantities \( r^\pm(x) \) and \( n(x) \) are all independent of the direction \( a \in \Gamma \) chosen to compute the eigenvalues of \( x \). In particular, all of the branches \( F_k \equiv \{ \lambda^k \geq 0 \} \) of \( \{ p = 0 \} \) are independent of the point \( a \in \Gamma \) chosen to compute the eigenvalues.

**Proof.** Choose \( a, b \in \Gamma \) and assume \( r^+_a(x) = k^* \) (cf. Remark 2.8). Let \( \gamma_1, \ldots, \gamma_m \) denote the \( m \) curves in the \((t, s)\)-plane defined by (2.19). Exactly \( k^* \) of these curves cross the negative \( s \)-axis. By (2.20) this implies that at exactly \( k^* \) of these curves cross the negative \( t \)-axis, i.e., \( r^+_b(x) = k^* \). The proof is similar for \( r^-(x) \) and \( n(x) \).

**Convexity**

**Corollary 2.13.**

(a) The Gårding cone \( \Gamma \) is convex.

(b) \( \lambda_{\min}(x) \) is concave.

(c) \( \lambda_{\max}(x) \) is convex.

(d) \( p(x)^{\frac{1}{m}} \) is concave on \( \Gamma \).

(e) \( -\log p(x) \) is convex on \( \Gamma \).

**Proof.** The conditions (a), (b) and (c) are equivalent by Proposition 2.6. Condition (d) follows from (2.4) in Remark 2.3. Since \( -p(x)^{\frac{1}{m}} \) is convex on \( \Gamma \), negative on \( \Gamma \), and zero on \( \partial \Gamma \), condition (a) follows. Finally, recall that if \( \varphi \) is increasing and convex,
then \( \varphi(f(x)) \) is convex if \( f \) is convex. To prove (e) take \( \varphi(t) = -\log(-t) \) for \( t < 0 \) and note that \( \varphi(-p(x)^{1/m}) = -\frac{1}{m} \log p(x) \).

**Second Proof of (a).** Suppose \( x, y \in \Gamma \), i.e., \( \lambda_{\min}(x) > 0 \) and \( \lambda_{\min}(y) > 0 \). We must show that \( \lambda_{\min}(sx + ty) > 0 \) for all \( s, t > 0 \). By Theorem 2.9, \( \Gamma_x = \Gamma_a \) so that we can assume the eigenvalues are computed using \( a = x \). Then by Properties (1a) and (2)

\[
\lambda_{\min}(sx + ty) = s + t \lambda_{\min}(y) > 0.
\]

**Remark 2.14.** For \( x \in W \), a hyperplane transverse to \( a \), we may apply Remark 2.5 to \( g(x) \equiv -\lambda_{\min}(x), x \in W \). Since \( g \) is convex, we prefer the following norm notation:

\[
\|x\|^+ = -\lambda_{\min}(x) \quad \text{and} \quad \|x\|^- = \|-x\|^+ = \lambda_{\max}(x) \quad \text{for } x \in W
\]

where the last equality follows from Property (1b). By Remark 2.5 we have

\[
\partial \Gamma = \{ \|x\|^+a + x : x \in W \} \quad \text{is the graph of} \quad \| \cdot \|^+,
\]

\[
-\partial \Gamma = \{-\|x\|^+a + x : x \in W \} \quad \text{is the graph of} \quad -\| \cdot \|^-.
\]

over the hyperplane \( W \). The convexity of \( \Gamma \) and 1(a) imply that

\[
\|x + y\|^+ \leq \|x\|^+ + \|y\|^+ \quad \text{and} \quad \|tx\|^+ = t\|x\|^+ \quad \text{for all } t > 0.
\]

**Monotonicity**

**Theorem 2.15.** The ordered eigenvalues are strictly \( \Gamma \)-monotone, that is

\[
\lambda_k^\uparrow(x + b) > \lambda_k^\uparrow(x) \quad \text{for all } x \in V, b \in \Gamma.
\]

**Proof.** Under the real analytic arrangement in Theorem 2.9 each of the restricted eigenvalue functions \( \lambda_k(t b + x) \) is strictly increasing in \( t \). Hence the ordered eigenfunctions

\[
\lambda_1^\uparrow(tb + x) \leq \cdots \leq \lambda_m^\uparrow(tb + x)
\]

are also strictly increasing. Now compare \( t = 0 \) with \( t = 1 \).

**Definition 2.16.** We say that a subset \( F \subset V \) is \( \Gamma \)-**monotone** if

\[
F + \Gamma \subset F \quad \text{or equivalently} \quad F + \Gamma \subset \text{Int} F.
\]

The equivalence follows since \( F + \Gamma \) is open.

**Corollary 2.17.** Each branch \( F_k \equiv \{ \lambda_k^\uparrow \geq 0 \} \) of \( \{ p = 0 \} \) is \( \Gamma \)-monotone.
Constructing Hyperbolic Polynomials

In this subsection we describe some of the important ways of constructing new hyperbolic polynomials from a given hyperbolic polynomial.

I. Factors and Products. Suppose \( p(x) \) and \( q(x) \) be real homogeneous polynomials with \( p(a), q(a) > 0 \) for fixed \( a \in V \). Then the following is obvious.

**Proposition 2.18.**

\[
p(x)q(x) \text{ is } a\text{-hyperbolic } \iff \ p(x) \text{ and } q(x) \text{ are each } a\text{-hyperbolic.}
\]

in which case \( \Gamma(pq) = \Gamma(p) \cap \Gamma(q) \).

II. Restriction. Suppose that \( W \) is a vector subspace of \( V \) and that \( a \in W \). Then the following is also obvious.

**Proposition 2.19.**

If \( p(x) \) is \( a\)-hyperbolic, then \( p|_{W} \) is \( b\)-hyperbolic for each \( b \in \Gamma(p) \cap W \)

in which case \( \Gamma(p|_{W}) = \Gamma(p) \cap W \).

III. Closure. Suppose \( \{p_j\} \) is a sequence of \( a\)-hyperbolic polynomials of degree \( m \) converging to a polynomial \( p \).

**Proposition 2.20.** If \( p(a) \neq 0 \), then \( p \) is \( a\)-hyperbolic.

**Proof.** Since \( p(a) \neq 0 \), the \( a\)-eigenvalues of \( x \in V \) are defined as complex numbers by (2.1). By continuity of the eigenvalues mod \( \pi m \), the limiting \( a\)-eigenvalues of \( p \) must be real. Obviously \( p(a) > 0 \) and degree of \( p \) equals \( m \).

IV. Derivatives. Let \( p' \) or \( p'_b \) denote the directional derivative of \( p \) in the direction \( b \), i.e.,

\[
p'(x) = \frac{d}{ds} p(x + sb)|_{s=0}
\] (2.22)

**Proposition 2.21.** Suppose \( p \) is \( a\)-hyperbolic of degree > 1. If \( b \in \Gamma(p) \), then \( p'_b \) is \( a\)-hyperbolic. That is, \( \Gamma(p) \subset \Gamma(p'_b) \). Moreover, for any \( x \) the ordered \( b\)-eigenvalues for \( p'_b \) are interspersed between the ordered \( b\)-eigenvalues for \( p \).

**Proof.** Note that by homogeneity \( p'_b(b) = mp(b) > 0 \). Also \( p'_b(tb + x) = \frac{d}{dt} p(tb + x) \), and therefore by Rolle’s Theorem the \( b\)-eigenvalues of \( x \) for \( p' \) are interspersed between the \( b\)-eigenvalues of \( x \) for \( p \). Namely, we have

\[
\lambda_1(x) \leq \lambda'_1(x) \leq \lambda_2(x) \leq \cdots \leq \lambda_{m-1}(x) \leq \lambda'_{m-1}(x) \leq \lambda_m(x).
\] (2.23)

More sharply stated,

(a) \( \lambda_k(x) < \lambda_{k+1}(x) \Rightarrow \lambda'_k(x) < \lambda'_{k+1}(x) \), and

(b) \( \lambda_k(x) \) has multiplicity \( \ell \) \( \Rightarrow \) \( \lambda'_k(x) \) has multiplicity \( \ell - 1 \).

16
Thus the $b$-eigenvalues of $x$ for $p'_b$ are all real, proving that $p'_b$ is $b$-hyperbolic. In particular, by (2.23), if $x \in \Gamma(p)$ (i.e., $\lambda_k(x) > 0$, $1 \leq k \leq m$), then $\lambda'_k(x) > 0$, for $1 \leq k \leq m - 1$ (i.e., $x \in \Gamma(p')$). Thus $\Gamma(p) \subset \Gamma(p'_b)$ proving that $p'_b$ is $a$-hyperbolic. 

By induction we have

**Corollary 2.22.** Suppose that $p$ is $\Gamma$-hyperbolic and $b_1, ..., b_k \in \Gamma$. Then the $k$-fold directional derivative $p^{(k)}_{b_1, ..., b_k}$ in the directions $b_1, ..., b_k$ is $\Gamma$-hyperbolic, i.e., $\Gamma(p) \subset \Gamma(p^{(k)})$.

**V. Elementary Symmetric Functions.**

Let $\sigma_k$ denote the $k$th elementary symmetric function of $m$ variables. If $p$ is a homogeneous polynomial of degree $m$ with $p(a) \neq 0$, then by (2.1)

$$p(sa + x) = p(a) \left[ s^m + \sigma_1(\lambda(x)) s^{m-1} + \cdots + \sigma_m(\lambda(x)) \right].$$

Taking directional derivatives in the direction $a$ we have

$$p^{(k)}(sa + x) = p(a) \left[ \alpha_0 s^{m-k} + \alpha_1 \sigma_1(\lambda(x)) s^{m-k-1} + \cdots + \alpha_{m-k} \sigma_{m-k}(\lambda(x)) \right]$$

with $\alpha_j = k!(\begin{smallmatrix} m-j \end{smallmatrix})$. Setting $s = 0$ proves that the $k$th directional derivative of $p$ in the direction $a$ is (up to a constant) the same as the $(m-k)$th elementary symmetric function of the $a$-eigenvalue functions, i.e.,

$$p^{(k)}(x) = k! \sigma_m(\lambda(x)).$$

In particular, this proves that

$$\sigma_j(x) \equiv \sigma_j(\lambda(x)) \text{ defines a homogeneous polynomial of degree } j$$

and that its derivative in the direction $a$ is $(m-j+1)$ times $\sigma_{j-1}(\lambda(x))$, i.e.,

$$\sigma'_j(x) = (m-j+1)\sigma_{j-1}(x)$$

By Corollary 2.22 this proves

**Corollary 2.23.** Suppose $p$ is $a$-hyperbolic. Then $\sigma_k(x) = \sigma_k(\lambda(x))$ defines an $a$-hyperbolic polynomial of degree $k$, and $\Gamma(\sigma_{k+1}) \subset \Gamma(\sigma_k)$ for $k = 1, ..., m$.

Let $\lambda^{(1)}_1(x), ..., \lambda^{(1)}_{m-k}(x) \mod \pi_{m-k}$ denote the $a$-eigenvalue functions for the $a$-hyperbolic polynomial $p^{(k)}(x)$. The equation (2.25) for $p^{(k)}(sa + x)$ proves that the $j$th elementary symmetric functions

$$\sigma_j(\lambda^{(k)}(x)) \text{ and } \sigma_j(\lambda(x)) \text{ are equal modulo a positive scale.}$$

**VI. Hyperbolic Polynomials Defined Universally.** Set $e = (1, ..., 1) \in \mathbb{R}^m$. Suppose that $Q$ is a symmetric homogeneous polynomial of degree $N$ on $\mathbb{R}^m$. If $p$
is a homogeneous polynomial of degree \( m \) on \( V \) with \( a \)-eigenvalue functions \( \lambda(x) = (\lambda_1(x), ..., \lambda_m(x)) \), then
\[
q(x) = Q(\lambda(x)) \tag{2.30}
\]
defines a homogeneous polynomial of degree \( N \) on \( V \) (since \( Q \) is a polynomial in the \( \sigma_\ell \)'s and each \( \sigma_\ell(\lambda(x)) \) is a polynomial). If \( Q \) is \( e \)-hyperbolic on \( \mathbb{R}^m \), let \( \Lambda_1(\lambda), ..., \Lambda_N(\lambda) \) denote the \( e \)-eigenvalue functions for \( Q \).

**Proposition 2.24.** Suppose \( Q \) is a symmetric \( e \)-hyperbolic polynomial of degree \( N \) on \( \mathbb{R}^m \). Then \( Q \) universally determines an \( a \)-hyperbolic polynomial \( q(x) \) defined by (2.30) on any vector space \( V \) equipped with an \( a \)-hyperbolic polynomial \( p(x) \) of degree \( m \). Moreover, the \( a \)-eigenvalue functions for \( q \) are \( \Lambda_1(\lambda(x)), ..., \Lambda_N(\lambda(x)) \).

**Proof.** First note that \( q(a) = Q(\lambda(a)) = Q(e) > 0 \). By (2.1) \( Q(te + \lambda) = Q(e) \prod_{j=1}^{N}(t + \Lambda_j(\lambda)) \). Property (2)′:
\[
\lambda(ta + x) = te + \lambda(x)
\]
implies that
\[
q(ta + x) = Q(\lambda(ta + x)) = Q(te + \lambda(x)) = Q(e) \prod_{j=1}^{N}(t + \Lambda_j(\lambda(x))).
\]
This proves that \( \Lambda_1(\lambda(x)), ..., \Lambda_N(\lambda(x)) \), which are real, are the \( a \)-eigenvalues of the polynomial \( q(x) \).

**Remark 2.25.** Examples of \( e \)-hyperbolic polynomials \( Q \) of degree \( N \) on \( \mathbb{R}^m \) abound. Take any \( a \)-hyperbolic polynomial \( R \) of degree \( N \) on a vector space \( W \). Choose vectors \( b_1, ..., b_m \in W \) with \( b \equiv b_1 + \cdots + b_m \in \Gamma(p) \). Then \( Q(\lambda) = R(\lambda_1 b_1 + \cdots + \lambda_m b_m) \) is \( e \)-hyperbolic of degree \( N \) on \( \mathbb{R}^m \). To use \( Q \) in Proposition 2.24 it should first be symmetrized (thereby increasing its degree).

Special cases of this construction \( V \) are of particular importance. (The trivial case \( Q(\lambda) = \lambda_1 \cdots \lambda_m \) induces the polynomial \( q = p \).) To begin exploring other cases note the following obvious

**Fact 2.26.** Given \( w \in \mathbb{R}^m \) the linear polynomial \( \ell(\lambda) \equiv w \cdot \lambda \) is \( e \)-hyperbolic if and only if \( \ell(e) = w \cdot e = w_1 + \cdots + w_m > 0 \), in which case the single \( e \)-eigenvalue function for \( \ell \) is computed to be
\[
\Lambda(\lambda) = \frac{w \cdot \lambda}{w \cdot e} \tag{2.31}
\]
This polynomial is not symmetric. Symmetrizing \( \ell(\lambda) \) yields \( Q(\lambda) = \prod_{\sigma \in \pi_m}(\sigma w) \cdot \lambda \) and we obtain the following important special case of Proposition 2.24.

**Proposition 2.27.** Suppose \( p \) is \( a \)-hyperbolic of degree \( m \) on \( V \) with \( a \)-eigenvalue functions \( \lambda(x) = (\lambda_1(x), ..., \lambda_m(x)) \mod \pi_m \). Fix \( w \in \mathbb{R}^m \) with \( w \cdot e > 0 \). Then
\[
q(x) = \prod_{\sigma \in \pi_m}(\sigma w) \cdot \lambda(x)
\]
defines an \( a \)-hyperbolic polynomial on \( V \) of degree \( m \) with \( a \)-eigenvalue functions
\[
\frac{(\sigma w) \cdot \lambda(x)}{w \cdot e}, \quad \sigma \in \pi_m.
\]
The convexity of the largest eigenvalue function generalizes as follows.

**Corollary 2.28. ([BGLS]).** Each non-decreasing linear combination of the ordered eigenvalue functions is convex:

\[ w \in \mathbb{R}^m \quad \Rightarrow \quad w \cdot \lambda^\uparrow (x) \text{ is convex on } V. \]

That is, for \( x, y \in V \) and \( 0 \leq s \leq 1 \) one has

\[ w \cdot \lambda^\uparrow (sx + (1 - s)y) \leq sw \cdot \lambda^\uparrow (x) + (1 - s)w \cdot \lambda^\uparrow (y) = w \cdot (s\lambda^\uparrow (x) + (1 - s)\lambda^\uparrow (y)). \]

**Proof.** Recall Property (4) that \( e \cdot \lambda^\uparrow (x) = \lambda_1 (x) + \cdots + \lambda_m (x) \) is a linear function of \( x \). Therefore, \( w \cdot \lambda^\uparrow (x) \) is convex \iff \( (w + te) \cdot \lambda^\uparrow (x) \) is convex,

and hence we may assume that \( w \cdot e > 0 \). Then it is easy to see that \( w \cdot \lambda^\uparrow (x)/w \cdot e \) is the largest eigenvalue function for \( q(x) \) defined in Proposition 2.27. Therefore, \( w \cdot \lambda^\uparrow (x) \) is convex by Corollary 2.13c.

Two particularly interesting choices for the \( w \in \mathbb{R}^m \) in Proposition 2.27 are

\[ w = (0, ..., 0, 1, ..., 1) \quad \text{with } k \text{ ones, and} \quad (2.32) \]

\[ w = (\delta, ..., \delta, \delta + 1) \quad \text{with } \delta > 0. \quad (2.33) \]

The first choice yields

**Proposition 2.29. (k-Fold Sums).** Suppose \( p \) is a-hyperbolic of degree \( m \) on \( V \). For each \( 1 \leq k \leq m \)

\[ q(x) = \prod_{|I|=k} ' (\lambda_{i_1} (x) + \cdots + \lambda_{i_k} (x)) \]

defines an a-hyperbolic polynomial of degree \( \binom{m}{k} \) on \( V \) whose eigenvalue functions are the \( k \)-fold sums

\[ \frac{1}{k} (\lambda_{i_1} (x) + \cdots + \lambda_{i_k} (x)) \quad i_1 < \cdots < i_k. \]

The second choice yields

**Proposition 2.30. ("\( \delta \)-Uniformly Elliptic").** Suppose \( p \) is a-hyperbolic of degree \( m \) on \( V \). For each \( \delta > 0 \)

\[ q_\delta (x) = \prod_{k=1}^{m} (\lambda_k (x) + \delta \text{tr} \lambda (x)) \]

defines an a-hyperbolic polynomial of degree \( m \) on \( V \) whose eigenvalue functions are \( \frac{1}{m \delta + 1} \) times

\[ \lambda_k (x) + \delta \text{tr} \lambda (x) \quad k = 1, ..., m. \]

The Gårding cones \( \Gamma_{\delta} \) for \( q_\delta \) form a conically-fundamental neighborhood system of the Gårding cone \( \Gamma \) for \( p \).
The Edge and the Polar

To begin we review some standard results for any non-empty open convex cone $\Gamma \subset V$ with vertex at the origin. Set

$$\Gamma^+ = \Gamma \quad \text{and} \quad \Gamma_+ = \Gamma^0$$  \hspace{1cm} (2.34)

where the polar $A^0$ of a closed convex cone $A$ with vertex at the origin is defined by

$$A^0 = \{ y \in V : (x, y) \geq 0 \ \forall \ x \in A \}.$$  

Recall the Bipolar Theorem: $(A^0)^0 = A$. Note that $\text{span} \Gamma^+ = V$ since $\Gamma$ is open and non-empty.

The edge of $\Gamma^+$ (or $\Gamma$) can be defined as

$$E = \{ x \in V : x + \Gamma^+ = \Gamma^+ \}$$  \hspace{1cm} (2.35)

One sees easily that $E$ is a convex cone contained in $\Gamma^+$, and since $x \in E \iff -x \in E$ ($x + \Gamma^+ = \Gamma^+ \iff \Gamma^+ = -x + \Gamma^+$), the edge $E$ must be a vector subspace of $V$. Moreover,

$$E \text{ contains any linear subspace of } \Gamma^+.$$  \hspace{1cm} (2.36)

The edge can also be defined by

$$E = \Gamma^+ \cap (-\Gamma^+).$$  \hspace{1cm} (2.37)

To see this recall that with $E$ defined by (2.35), $E \subset \Gamma^+ \cap (-\Gamma^+)$ was noted above. If $x \in \Gamma^+ \cap (-\Gamma^+)$, then the line through $x$ is a subset of $\Gamma^+$. By (2.36) this line is a subset of the edge $E$ defined by (2.35).

Again for a general open convex cone $\Gamma$ we have:

$$E \text{ and } \text{span} \Gamma_+ \text{ are polar cones.}$$  \hspace{1cm} (2.38)

**Proof.** Note that $E \subset \Gamma^+ \Rightarrow \Gamma_+ \subset E^0$ and hence $\text{span} \Gamma_+ \subset E^0$. Also we have $\Gamma_+ \subset \text{span} \Gamma_+ \Rightarrow (\text{span} \Gamma_+)^0 \subset \Gamma^+$. The polar of a vector space is a vector space, hence by (2.36) we have $(\text{span} \Gamma_+)^0 \subset E$. Now apply the Bipolar Theorem. \hfill \blacksquare

If $E = \{0\}$, then $\Gamma^+$ is said to be complete. This is equivalent to $V = \text{span} \Gamma_+$ or $\Gamma_+ = \text{Int} \Gamma_+$ by (2.38).

Now we assume that $\Gamma$ is the Gårding cone of an $a$-hyperbolic polynomial $p$. Then the edge $E$ of $\Gamma(p)$ can be described in several ways.

**THEOREM 2.31.** Suppose $p$ is an $a$-hyperbolic polynomial with Gårding cone $\Gamma$.

(a) The edge $E$ of $\Gamma$ equals the null set of $p$, i.e.,

$$E = \{ x \in V : \lambda_1(x) = \cdots = \lambda_m(x) = 0 \}.$$  \hspace{1cm} (2.39)
(b) The edge $E$ of $\Gamma$ equals the linearity of $p$, i.e.,

$$E = \{ x \in V : p(b + tx) = p(b) \ \forall \ t \in \mathbb{R}, b \in V \}. \quad (2.40)$$

(c) $x \in E \iff p'_{x} \equiv 0$.

**Proof of (a).** By 1(b) the negative of the Gårding cone, $-\Gamma^+$, is the set of points $x \in V$ whose $a$-eigenvalues are all $\leq 0$. Thus $E = \Gamma^+ \cap (-\Gamma^+)$ is the null set of $p$.

**Proof of (b) and (c).** Apply Property (3), and then for (b) note that $p(b + tx) - p(b)$ vanishes for all $b \in \Gamma$ if and only if it vanishes for all $b \in V$.

This has several important consequences. First, taking derivatives does not change the edge.

**Corollary 2.32.** Suppose $p$ is $a$-hyperbolic of degree $m \geq 2$. Then

$$\text{Edge}(p'_{a}) = \text{Edge}(p).$$

**Proof.** By (2.23) $\text{Edge}(p'_{a}) \supset \text{Edge}(p)$. If $\lambda'_1(x) = \cdots = \lambda'_{m-1}(x) = 0$, then all $\lambda_k(x)$ vanish by the sharp application (2.23)' of Rolle’s Theorem given in the proof of Proposition 2.21.

Second, the edge of the restriction is the restriction of the edge.

**Corollary 2.33.** Suppose $p$ is $a$-hyperbolic polynomial on $V$, and that $W$ is a subspace of $V$. If $\Gamma \cap W \neq \emptyset$, then

$$\text{Edge} \left( p \big|_W \right) = \text{Edge}(p) \cap W.$$ 3. $\Gamma$-Monotone Sets

The Dirichlet problem will be studied (and solved) for equations determined by subsets $F$ of $V = \text{Sym}^2(\mathbb{R}^n)$ which are $\Gamma$-monotone. In this section we discuss these subsets. Recall that by Corollary 2.17 they include all branches of $\{ p = 0 \}$. Throughout this section we assume that $p$ is a given $a$-hyperbolic polynomial, $\Gamma$ is the associated Gårding cone, and $\lambda_1(x), \ldots, \lambda_m(x)$ are the $a$-eigenvalue functions.

**The Structure Theorem**

Recall (4) that

$$\text{trace}(x) = \lambda_1(x) + \cdots + \lambda_m(x). \quad (3.1)$$

(i.e., the elementary symmetric function $\sigma_1(x)$) is a linear function of $x$. Define the hyperplane

$$V_0 \equiv \{ x \in V : \text{trace}(x) = 0 \}.$$
We adopt the notation in Remark 2.14 with \( W = V_0 \).

**Definition 3.1.** A function \( f : V_0 \to \mathbb{R} \) is \( \| \cdot \|^{\pm}\)-Lipschitz if
\[
-\|y\|^+ \leq f(x+y) - f(x) \leq \|y\|^+ \quad \text{for all } x, y \in V_0.
\] (3.2)

**THEOREM 3.2.** (The Structure Theorem). Suppose \( F \) is a closed subset of \( V \) with \( \emptyset \neq F \neq V \). If \( F \) is \( \Gamma \)-monotone, then there exists a \( \| \cdot \|^{\pm}\)-Lipschitz function \( f : V_0 \to \mathbb{R} \) such that
\[
\partial F = \{ f(x)a + x : x \in V_0 \} \quad \text{is the graph of } f,
\] (3.3)
and
\[
F = \{ ta + x : t \geq f(x) \text{ and } x \in V_0 \} \quad \text{is the upper graph of } f.
\] (3.4)
Conversely, each such \( f \) defines a \( \Gamma \)-monotone set \( F \) via (3.4).

**Corollary 3.3.** Suppose \( F \) is a closed subset of \( V \) which is \( \Gamma \)-monotone. Then \( \text{Int} F \) is a connected open set with \( F = \text{Int} F \). Moreover, \( F \) is uniquely determined by its boundary since \( F = \partial F + \Gamma \).

**Example 3.4.** (Positive-Orphant-Monotone). Take \( V \equiv \mathbb{R}^m \) and \( p(\lambda) \equiv \lambda_1 \cdots \lambda_m \) where \( \lambda = (\lambda_1, \ldots, \lambda_m) \in \mathbb{R}^m \). Set \( e = (1, \ldots, 1) \). Then \( p \) is \( e \)-hyperbolic with eigenvalues \( \lambda_1, \ldots, \lambda_m \) at \( \lambda \). The closure \( \overline{\Gamma} \) of the Gårding cone is the closed positive orphant \( \mathbb{R}^m_+ \). The traceless hyperplane \( V_0 \) is the orthogonal complement of \( e \) while \( \|\lambda\|^+ = -\lambda_{\min} \) and \( \|\lambda\|^-=\lambda_{\max} \). If \( E \) is a closed subset of \( \mathbb{R}^m \) with \( \emptyset \neq E \neq \mathbb{R}^m \), and \( E \) is \( \mathbb{R}^m_+ \) -monotone, then there exists \( f : V_0 \to \mathbb{R} \) which is \( \| \cdot \|^{\pm}\)-Lipschitz continuous such that \( \partial E \) is the graph of \( f \) over \( V_0 \) and \( E \) is the upper graph of \( f \) over \( V_0 \).

The next example is the key example for studying the Dirichlet problem.

**Example 3.5.** (The Structure of \( \mathcal{P} \)-Monotone Sets). Take \( V = \text{Sym}^2(\mathbb{R}^n) \) and \( p(A) = \text{det}A \). Then \( p \) is \( I \)-hyperbolic with eigenvalues exactly the standard eigenvalues of \( A \). The closed Gårding cone \( \overline{\Gamma} = \mathcal{P} \equiv \{ A \geq 0 \} \). Consider the hyperplane
\[
\text{Sym}^2_0(\mathbb{R}^n) \equiv \{ A \in \text{Sym}^2(\mathbb{R}^n) : \text{tr}A = 0 \}.
\]
If \( F \) is a non-trivial closed subset of \( \text{Sym}^2(\mathbb{R}^n) \) \((\emptyset \neq F \neq \text{Sym}^2(\mathbb{R}^n))\) which is \( \mathcal{P} \)-monotone, then there exists a function \( f : \text{Sym}^2_0(\mathbb{R}^n) \to \mathbb{R} \), which is \( \| \cdot \|^{\pm}\)-Lipschitz, such that
\[
F = \{ tI + A : A \in \text{Sym}^2_0(\mathbb{R}^n) \text{ and } t \geq f(A) \} \quad \text{is the upper graph of } f.
\] (3.5)
Moreover, the properties of \( F \) enumerated in Corollary 3.3 hold.

**Proof of Theorem 3.2.** The monotonicity hypothesis \( F + \Gamma \subset F \) implies that the set \( \ell_x = \{ t \in \mathbb{R} : ta + x \in F \} \) is either empty, all of \( \mathbb{R} \), or of the form \( [c, \infty) \) with \( c \in \mathbb{R} \). If \( \ell_x = \emptyset \), then \( F = \emptyset \) since the existence of \( y \in F \) implies that \( x + ta = y + (x - y + ta) \in F \) if \( t \) is chosen large enough so that \( x - y + ta \in \Gamma \). If \( \ell_x = \mathbb{R} \), then \( F = V \) since for each
y ∈ V, if t << 0, then y − x − ta ∈ Γ which implies that y = x + ta + (y − x − ta) ∈ F + Γ ⊂ F.

Since V is neither empty nor all of V, there is a well-defined function f : V₀ → R such that ℓₓ = [f(x), ∞). Note that ∂F is the graph of f over V₀. This proves (3.3) and (3.4).

We now claim that if F is the upper graph of f as in (3.4), then

\[ F \text{ is } Γ\text{-monotone} \iff F \text{ is } \| · \|_{±}\text{-Lipschitz}. \]

To see this suppose \( \bar{x} = f(x)a + x, x ∈ V₀ \), is a point on the graph of f. Then the cone \( \bar{x} + Γ \) lies above the graph of F if and only if

\[ f(x + y) ≤ f(x) + \| y \|_{±} \text{ for all } y ∈ V₀ \]

by Remark 2.14. This inequality for all \( y ∈ V₀ \) is equivalent to

\[ -\| y \|_{−} ≤ f(x + y) − f(x) \text{ for all } x, y ∈ V₀. \]

A Universal Construction of Γ-Monotone Subsets

Let \( E ⊂ \mathbb{R}^m \) be a closed subset which is symmetric, i.e., invariant under the permutation of coordinates on \( \mathbb{R}^m \). Then E universally determines a subset \( F_E = F_E(p) ⊂ V \) for each \( a \)-hyperbolic polynomial \( p \) of degree \( m \) on \( V \) by setting

\[ F_E = \{ x ∈ V : λ(x) ∈ E \} = λ^{-1}(E) \] (3.6)

where \( λ(x) \) is the eigenvalue map (defined mod \( π_m \)). If \( E \) is a cone, then \( F_E \) is a cone. Note that the Gårding cone \( Γ \) for \( p \) is universally determined by the positive orphant \( \mathbb{R}^m_{+} \). The next three theorems will be incorporated into one of our main results (Theorem 5.19) on the Dirichlet problem. The most basic for this application is the following.

**THEOREM 3.6.** Suppose \( E \) is a closed symmetric subset of \( \mathbb{R}^m \).

If \( E \) is \( \mathbb{R}^m_{+} \)-monotone, then \( F_E \) is \( Γ \)-monotone.

**Proof.** Suppose \( x ∈ F_E \), i.e., \( λ_a(x) ∈ E \). Pick \( b ∈ Γ \). Using the real analytic arrangement Theorem 2.9 states that the vector \( λ^+ \) with coordinates \( λ^+_k ≡ λ^+_k(x + b) − λ^+_k(x) \) satisfies

\[ λ^+ ∈ \mathbb{R}^m_{+}. \]

Hence \( λ_a(x + b) = λ_a(x) + λ^+ ∈ E + \mathbb{R}^m_{+} ⊂ E \) proving that \( x + b ∈ F_E \). ■

Given an \( a \)-hyperbolic polynomial \( p \) of degree \( m \) with eigenvalue map \( λ(x) \) and Gårding cone \( Γ \), consider the conical neighborhoods \( Γ_δ \) of \( Γ \) defined by

\[ λ_k(x) + δtrλ(x) ≥ 0 \quad k = 1, ..., m. \]
as in Proposition 2.30. Let \((R_+^m)_\delta \subset R^m\) denote the conical neighborhood of the positive orphan \(R_+^m\) defined by
\[
\lambda_k + \delta \text{tr} \lambda \geq 0 \quad k = 1, \ldots, m
\]

**THEOREM 3.7.** Suppose that \(E\) is a closed symmetric subset of \(R^m\) and \(\delta > 0\).

If \(E\) is \((R_+^m)_\delta\)-monotone, then \(F_E\) is \(\Gamma_\delta\)-monotone.

**Proof.** Consider the \(a\)-hyperbolic polynomial \(q_\delta\) defined in Proposition 2.30. It has eigenvalue map (up to scale) \(\Lambda(x) = \lambda(x) + (\delta \text{tr} \lambda(x)) e\), and Gårding cone \(\Gamma_\delta = \Lambda^{-1}(R_+^m)\). In order to apply Theorem 3.6 to \(q_\delta\) consider the linear map \(L : R^m \rightarrow R^m\) defined by \(L(\lambda) = \lambda + (\delta \text{tr} \lambda) e\). Note that \(L^{-1}(\Lambda) = \Lambda - \left(\frac{\delta}{1 + m \delta} \text{tr} \Lambda\right) e\). It suffices to show that:
\[
F_E = \Lambda^{-1}(LE), \quad \text{and that}
\]
\(E\) is \((R_+^m)_\delta\) monotone \(\iff\) \(LE\) is \(R_+^m\) monotone \(\quad (3.7)\)

to conclude by Theorem 3.6 that \(F_E = \Lambda^{-1}(LE)\) is \(\Gamma_\delta = \Lambda^{-1}(R_+^m)\)-monotone. First, \(\Lambda(x) = L\lambda(x)\) implies \(F_E = \lambda^{-1}(E) = \Lambda^{-1}(LE)\). Second, \((R_+^m)_\delta = L^{-1}R_+^m\) implies \(3.7)\).

Finally we prove a recent convexity result of Bauschke, Güler, Lewis and Sendov [BGLS] stated first with our applications in mind.

**THEOREM 3.8.** Suppose that \(E\) is a symmetric subset of \(R^m\).

If \(E\) is convex, then \(F_E\) is convex.

**Proof.** Suppose \(x \notin F_E\), i.e., \(\lambda^\uparrow(x) \notin E\). It will suffice to exhibit a convex set \(A\) which contains \(F_E\) but not \(x\).

Note that by Corollary 2.28, for each \(w^\uparrow \in R_+^m\), the set
\[
A \equiv \{ y \in V : w^\uparrow(\lambda^\uparrow(y)) < 1 \}
\]
is convex. By the Hahn-Banach Theorem there exists a \(w \in (R^m)^*\) such that
\[
\sup_E w < 1 = w(\lambda^\uparrow(x)) .
\]
Since \(\sup_E w^\uparrow = \sup_E w\) and \(w(\lambda^\uparrow(x)) \leq w^\uparrow(\lambda^\uparrow(x))\),
\[
\sup_E w^\uparrow < 1 \leq w^\uparrow(\lambda^\uparrow(x)) . \quad \blacksquare
\]

**Remark 3.9.** Adopt the notation in Corollary 2.28 and set \(u \equiv \lambda^\uparrow(sx + (1 - s)y), v = s\lambda^\uparrow(x) + (1 - s)\lambda^\uparrow(y)\). Then for \(w^\uparrow \in R_+^m\) the Corollary concludes that \(w^\uparrow(u) \leq w^\uparrow(v)\). Now
\[
u \in E \equiv \text{the convex hull of the orbit } \pi_m v. \quad (3.8)
\]

24
Otherwise, as in the proof of Theorem 3.8, there would exist \( w^\uparrow \in R_\uparrow^m \) with
\[
\sup_E w^\uparrow < 1 \leq w^\uparrow(u)
\]
which contradicts \( w^\uparrow(u) \leq w^\uparrow(v) \).

**THEOREM 3.10.** Suppose \( f \) is a symmetric function on \( R^m \).

If \( f(\lambda) \) is convex, then \( f(\lambda(x)) \) is convex \( (3.9) \)

**Proof.** Note that by (3.8) there exist \( v_1, \ldots, v_N \) in the orbit \( \pi_m v \) and \( 0 \leq t_j \leq 1 \), \( j = 1, \ldots, N \) with \( \sum_j t_j = 1 \) such that
\[
u = \sum_j t_j v_j.
\]
By the convexity and symmetry of \( f \),
\[
f(u) = f\left(\sum_j t_j v_j\right) \leq \sum_j t_j f(v_j) = \sum_j t_j f(v) = f(v).
\]

4. The Dirichlet Problem

In this section we summarize without proof the existence and uniqueness theorem in [HL1] for the Dirichlet problem. It can be read independently of Sections 2 and 3. The equations considered are on euclidean space. They are purely second order and have constant coefficients; but are fully nonlinear and degenerate elliptic.

**Subequations and Positivity**

Each subset \( F \subset \text{Sym}^2(R^n) \) determines a class of \( C^2 \)-functions \( u \) on an open subset \( X \subset R^n \) by the requirement that its hessian (second derivative) \( D^2 u(X) \) lie in \( F \) at each \( x \in X \). This class in \( C^2(X) \) can be extended to a class in \( \text{USC}(X) \), the upper semi-continuous \([-\infty, \infty]\)-valued functions on \( X \), provided that \( F \) satisfies monotonicity with respect to the set
\[
P \equiv \{ A \in \text{Sym}^2(R^n) : A \geq 0 \} \quad (4.1)
\]
Two justifications for imposing this condition are given in Remark 4.3 and Remark 4.10.

**Definition 4.1.** A closed subset \( F \subset \text{Sym}^2(R^n) \) with \( \emptyset \neq F \neq \text{Sym}^2(R^n) \) will be called a subequation or Dirichlet set if \( F \) satisfies the positivity condition
\[
F + P \subset F. \quad (4.2)
\]

The Structure Theorem 3.2 for \( P \)-monotone sets, as explained in Example 3.5, is now the “Structure Theorem for Subequations”. In particular, Corollary 3.3 states that \( \text{Int} F \) is connected, \( F = \text{Int} F \), and \( F \) is completely determined by its boundary. In fact, it is the upper graph of a Lipschitz function on \( \text{Sym}^2_0(R^n) = \{ \text{tr} A = 0 \} \).
Definition 4.2. Suppose that \( F \subseteq \text{Sym}^2(\mathbb{R}^n) \) is a subequation and \( u \in C^2(X) \) (where \( X \) is an open subset of \( \mathbb{R}^n \)). If \( D^2u(x) \in F \) for all \( x \in X \), then \( u \) is called \( F \)-subharmonic on \( X \). If \( D^2u(x) \in \text{Int} F \) for all \( x \in X \), then \( u \) is called strictly \( F \)-subharmonic on \( X \). If \( D^2u(x) \in \partial F \) for all \( x \in X \), then \( u \) is called \( F \)-harmonic on \( X \).

Remark 4.3. (Motivation). This definition of \( F \)-subharmonicity will be extended to non-differentiable functions. Perhaps the most fundamental property is that the maximum \( \max\{u, v\} \) of two \( F \)-subharmonic functions \( u \) and \( v \) is again \( F \)-subharmonic. Computing the distributional hessian of \( \max\{u, v\} \) in the case where \( u \) and \( v \) are \( C^2 \) provides strong support for assuming positivity if one wants \( \max\{u, v\} \) to be \( F \)-subharmonic. (See Remark 3.3 in [HL1]).

Dirichlet Duality

Each subequation \( F \) has a natural “dual” subequation.

Definition 4.4. The Dirichlet dual of a subequation \( F \subseteq \text{Sym}^2(\mathbb{R}^n) \) is the set
\[
\tilde{F} = \sim (\sim \text{Int} F) = - (\sim \text{Int} F).
\] (4.3)

Proposition 4.5. The Dirichlet dual \( \tilde{F} \) of a subequation \( F \) is also a subequation. Furthermore, duality holds, that is
\[
\tilde{\tilde{F}} = F. 
\] (4.4)

Proof. Assertion (4.4) follows straightforwardly from the fact that \( F = \overline{\text{Int} F} \). To prove that \( \tilde{F} \) satisfies (4.2) a lemma is required.

Lemma 4.6. Suppose \( F = \overline{\text{Int} F} \). Then
\[
F + A = \tilde{F} - A \quad \text{for each} \quad A \in \text{Sym}^2(\mathbb{R}^n).
\] (4.5)

Proof. Note that \( B \in \tilde{F} + A \iff -B \notin \text{Int} (F + A) = \text{Int} F + A \iff -(B + A) \notin \text{Int} F \iff B + A \in \tilde{F} \).

Proof of Proposition 4.5. Suppose \( P \in \mathcal{P} \). Then \( F + P \subseteq F \), or equivalently \( F \subseteq F - P \). Taking duals reverses this inclusion and by Lemma 4.6, \( \tilde{F} - P = \tilde{F} + P \). Thus \( \tilde{F} + P \subseteq \tilde{F} \) as desired.

Proposition 4.7. Suppose \( F \) is a subequation and \( u \in C^2(X) \). Then
\[
u \text{ is } F\text{-harmonic} \iff \text{u is } F\text{-subharmonic and } -u \text{ is } \tilde{F}\text{-subharmonic.}
\]

Proof. Note that \( \partial F = F \cap (\sim \text{Int} F) = F \cap (-\tilde{F}) \).

F-Subharmonic and F-Harmonic Functions
It is necessary and quite useful to extend the definition of $F$-subharmonic to non-differentiable functions $u$. Let $USC(X)$ denote the set of $[-\infty, \infty]$-valued, upper semi-continuous functions on $X$.

**Definition 4.8.** A function $u \in USC(X)$ is said to be $F$-subharmonic if for each $x \in X$ and each function $\varphi$ which is $C^2$ near $x$, one has that

\[
\left\{ \begin{array}{l}
u - \varphi \leq 0 \text{ near } x_0 \\
= 0 \text{ at } x_0
\end{array} \right. \quad \Rightarrow \quad D^2_x \varphi \in F. \quad (4.6)
\]

Note that if $u \in C^2(X)$, then

\[
u \in F(X) \quad \Rightarrow \quad D^2_x u \in F \quad \forall \quad x \in X
\]

since the test function $\varphi$ may be chosen equal to $u$ in (4.10). The converse is not true for general subsets $F$. However, we have the following.

**Proposition 4.9.** Suppose $F$ satisfies the Positivity Condition (4.2) and $u \in C^2(X)$. Then

\[
D^2_x u \in F \quad \text{for all } x \in X \quad \Rightarrow \quad u \in F(X).
\]

**Proof.** Assume $D^2_x u \in F$ and $\varphi$ is a $C^2$-function such that

\[
\left\{ \begin{array}{l}
u - \varphi \leq 0 \text{ near } x_0 \\
= 0 \text{ at } x_0
\end{array} \right.
\]

Since $(\varphi - u)(x_0) = 0$, $Dx_0(\varphi - u) \in \mathcal{P}$, and $\varphi - u \geq 0$ near $x_0$, we have $D^2_{x_0}(\varphi - u) \in \mathcal{P}$. Now the Positivity Condition implies that $D^2_{x_0} \varphi \in D^2_{x_0} u + \mathcal{P} \subset F$. This proves that $u \in F(X)$.

**Remark 4.10.** Because of Proposition 4.9 we must assume that $F$ satisfies the Positivity Condition. Otherwise the definition of $F$-subharmonicity would not extend the natural one for smooth functions (cf. Remark 4.3). The positivity condition is rarely used in proofs. This is because without it $F(X)$ is empty and the results are trivial. For example, the positivity condition is not required in the following theorem. ($F$ need only be closed.)

It is remarkable, at this level of generality, that $F$-subharmonic functions share many of the important properties of classical subharmonic functions.

**THEOREM 4.11.** Elementary Properties of F-Subharmonic Functions. Let $F$ be an arbitrary closed subset of $J^2(X)$.

(Maximum Property) If $u, v \in F(X)$, then $w = \max\{u, v\} \in F(X)$.

(Coherence Property) If $u \in F(X)$ is twice differentiable at $x \in X$, then $J^2_x u \in F_x$.

(Decreasing Sequence Property) If $\{u_j\}$ is a decreasing ($u_j \geq u_{j+1}$) sequence of functions with all $u_j \in F(X)$, then the limit $u = \lim_{j \to \infty} u_j \in F(X)$.
(Uniform Limit Property) Suppose \( \{u_j\} \subset F(X) \) is a sequence which converges to \( u \) uniformly on compact subsets to \( X \), then \( u \in F(X) \).

(Families Locally Bounded Above) Suppose \( \mathcal{F} \subset F(X) \) is a family of functions which are locally uniformly bounded above. Then the upper semicontinuous regularization \( v^* \) of the upper envelope

\[ v(x) = \sup_{f \in \mathcal{F}} f(x) \]

belongs to \( F(X) \).

**Proof.** See Appendix B in [HL2].

---

**Boundary Convexity**

Associated to each subequation \( F \) is an open cone \( \overrightarrow{F} \) which governs the geometry of those domains for which the Dirichlet problem is always solvable. If \( F \) is a cone with vertex at the origin, then \( \overrightarrow{F}' = \text{Int} F \). Otherwise, \( \overrightarrow{F}' \) is constructed as in [HL1, pp. 415-416]. Here is a summary.

Fix a vertex \( B \in \text{Sym}^2(\mathbb{R}^n) \) and consider the ray sets:

\[
\overrightarrow{F}_B = \{A \in \text{Sym}^2(\mathbb{R}^n) : B + tA \in F \ \forall \ t \geq \text{some } t_0\} \quad (4.7)
\]

\[
\overrightarrow{F}_B' = \{A \in \text{Sym}^2(\mathbb{R}^n) : B + tA \in \text{Int} F \ \forall \ t \geq \text{some } t_0\} \quad (4.8)
\]

Examples show that \( \overrightarrow{F}_B \) may not be closed, \( \overrightarrow{F}_B' \) may not be open, and \( \overrightarrow{F}_B, \overrightarrow{F}_B' \) may depend on \( B \). However,

\[
\overrightarrow{F} \equiv \text{closure} \overrightarrow{F}_B \quad \text{and} \quad \overrightarrow{F}' \equiv \text{Int} \overrightarrow{F}_B' \quad (4.9)
\]

are independent of the choice of vertex \( B \). In addition

\( \overrightarrow{F} \) is a subequation which is a cone with vertex at the origin. \hspace{1cm} (4.10)

Moreover, by Lemma 5.8 and Elementary Property (3),

\[
\overrightarrow{F}' = \text{Int} \overrightarrow{F} \quad \text{and} \quad \overrightarrow{F} \equiv \text{closure} \overrightarrow{F}' \quad (4.11)
\]

**Definition 4.12.** We call \( \overrightarrow{F}' \) the **asymptotic interior** of \( F \), and \( \overrightarrow{F} \) the **asymptotic subequation** of \( F \). (In [HL1], \( \overrightarrow{F} \) is called the “asymptotic ray set associated to \( F \”).)

Note that (4.10) and (4.11) imply that

\[
\text{Int} \mathcal{P} \subset \overrightarrow{F}' = \text{Int} \overrightarrow{F}. \quad (4.12)
\]
Suppose now that \( \Omega \subset \mathbb{R}^n \) is a domain with smooth boundary \( \partial \Omega \). Let \( \rho \) be a local defining function for \( \partial \Omega \) at a point \( x \), that is, a smooth function with \( |\nabla \rho| > 0 \), defined on a neighborhood \( U \) of \( x \), such that \( U \cap \Omega = \{ \rho < 0 \} \).

**Definition 4.13.** The boundary \( \partial \Omega \) is strictly \( \overrightarrow{F} \)-convex at \( x \) if

\[
\text{Hess}_x \rho \big|_{T_x \partial \Omega} = B \big|_{T_x \partial \Omega} \quad \text{for some } B \in \overrightarrow{F}' \equiv \text{Int} \overrightarrow{F}.
\]

This is independent of the choice of \( \rho \) and is equivalent to the condition that:

\[
\text{Hess}_x \rho + tP_n \in \overrightarrow{F}' \equiv \text{Int} \overrightarrow{F} \quad \forall \, t \geq \text{some } t_0
\]

(4.14)

where \( P_n \) denotes orthogonal projection onto the normal line to \( \partial \Omega \) at \( x \).

Note that each classically strictly convex boundary is strictly \( \overrightarrow{F} \)-convex by (4.12). In general \( \overrightarrow{F} \)-convexity can be expressed purely in terms of the geometry of the boundary. Let \( II \) denote the second fundamental form of \( \partial \Omega \) with respect to the interior normal at \( x \). Then \( \partial \Omega \) is strictly \( \overrightarrow{F} \)-convex at \( x \) if and only if either of the following equivalent conditions holds.

\[
II = B \big|_{T_x \partial \Omega} \quad \text{for some } B \in \overrightarrow{F}
\]

\[
II + tP_n \in \overrightarrow{F}' \equiv \text{Int} \overrightarrow{F} \quad \forall \, t \geq \text{some } t_0
\]

The concept of \( \overrightarrow{F} \)-convexity is important because it leads to the existence of local barriers used in existence proofs. For domains \( \Omega \subset \mathbb{R}^n \) we have the following global result.

**Theorem 4.14.** Suppose \( \partial \Omega \) is strictly \( \overrightarrow{F} \)-convex at each point. Then there exists a global defining function \( \rho \in C^\infty(\overline{\Omega}) \) and constants \( \epsilon_0 > 0, R_0 > 0 \) such that

\[
C (\rho + \frac{\epsilon_0}{2} |x|^2) \text{ is strictly } F\text{-subharmonic on } \Omega \text{ for all } C \geq C_0 \text{ and } 0 \leq \epsilon \leq \epsilon_0.
\]

See [HL1, §5] for proofs of the above.

### Existence and Uniqueness

**Theorem 4.15.** Suppose \( F \) is a subequation in \( \text{Sym}^2(\mathbb{R}^n) \) and \( \Omega \) is a bounded domain in \( \mathbb{R}^n \) with smooth boundary \( \partial \Omega \). If \( \partial \Omega \) is both \( \overrightarrow{F} \) and \( \overrightarrow{\tilde{F}} \) strictly convex, then the Dirichlet problem is uniquely solvable for all continuous boundary data. That is, for each \( \varphi \in C(\partial \Omega) \), there exists a unique \( u \in C(\overline{\Omega}) \) satisfying:

1. \( u \) is \( F \)-harmonic on \( \Omega \), and
2. \( u = \varphi \) on \( \partial \Omega \).

Since \( \mathcal{P} \subset \overrightarrow{F} \) and \( \mathcal{P} \subset \overrightarrow{\tilde{F}} \), if \( \partial \Omega \) is strictly convex (in the standard way), then it is both \( \overrightarrow{F} \) and \( \overrightarrow{\tilde{F}} \) strictly convex. In particular, the Dirichlet problem is uniquely solvable on all domains with strictly convex boundaries, such as a ball.
This Theorem 4.15 was first proved in [HL1]. The proof involved the use of “subaffine” functions (equivalently $\tilde{P}$-subharmonic functions) and relied on a deep result of Slodkowski on quasi-convex functions [S]. The following definition of $F$-subharmonic functions was adopted there.

**Definition 4.8’.** A function $u \in \text{USC}(X)$ is said to be $F$-subharmonic if for each $x \in X$ and each $C^2$-function $v$ which is $F$-subharmonic near $x$, the sum $u + v$ is subaffine near $x$.

See Remark 4.9 in [HL1] for a proof that Definitions 4.9 and 4.9’ are equivalent.

A second proof of Theorem 4.15 was given in [HL2] using standard viscosity methods, i.e., the Theorem on Sums and Definition 4.8 (see [C], [CIL]).
5. Subequations Determined by Hyperbolic Polynomials

Gårding’s theory provides a unified approach to studying many basic subequations. For this application to subequations we only consider polynomials on the vector space $V \equiv \text{Sym}^2(\mathbb{R}^n)$ which are hyperbolic in the direction $I$.

**Dirichlet-Gårding Polynomials**

**Definition 5.1.** A homogeneous real polynomial $M$ of degree $m$ on $\text{Sym}^2(\mathbb{R}^n)$ is $I$-hyperbolic if $M(I) > 0$ and for all $A \in \text{Sym}^2(\mathbb{R}^n)$ the polynomial $M_A(s) = M(sI + A)$ has $m$ real roots.

We adopt the terminology and notation from the previous discussion, with $\Gamma$ denoting the Gårding cone associated to the polynomial $M$. The principal branch (or closed Gårding cone) $F_1 = \overline{\Gamma}$ is defined by $\lambda_k(A) \geq 0$, $k = 1, \ldots, m$, and is a convex cone (Corollary 2.13) but may not be a subequation. We require that $\overline{\Gamma}$ be a subequation.

**Definition 5.2.** An $I$-hyperbolic polynomial $M$ on $\text{Sym}^2(\mathbb{R}^n)$ is said to be a Dirichlet-Gårding polynomial if $\overline{\Gamma}$ is a subequation, i.e., if positivity holds:

1. $\overline{\Gamma} + \mathcal{P} \subset \overline{\Gamma}$.

**Remark 5.3.** There are other useful ways of stating this positivity condition for $\overline{\Gamma}$. Since $\overline{\Gamma}$ is a convex cone, (1) is equivalent to

2. $\mathcal{P} \subset \overline{\Gamma}$, that is, $A \geq 0 \Rightarrow \lambda_k(A) \geq 0$, $k = 1, \ldots, m$.

In other words, for $A \geq 0$, all the roots of the polynomial $t \mapsto M(tI + A)$ are $\leq 0$. Equivalently,

2′. $M(tI + A) \neq 0$ if $A \geq 0$ and $t > 0$.

Since the extreme rays in $\mathcal{P}$ are generated by orthogonal projections $P_e$ with $e \in \mathbb{R}^n$, it is enough to verify (2) for $A = P_e$.

3. $\lambda_k(P_e) \geq 0$ for all unit vectors $e \in \mathbb{R}^n$ and $k = 1, \ldots, m$.

3′. $M(tI + P_e) > 0$ for all $t > 0$ and all unit vectors $e \in \mathbb{R}^n$.

By definition the branches $F_k$ are subequations if positivity holds. That is,

4. $F_k + \mathcal{P} \subset F_k$ for all $k = 1, \ldots, m$.

By Corollary 2.17 and the convexity of the principal branch $\overline{\Gamma} = F_1$, condition (4) is equivalent to condition (2). Finally, by the Structure Theorem 3.2 the condition that:

5. The ordered eigenvalue function $\lambda_k^\downarrow(x) = \|x\|^\pm$-Lipschitz ($k = 1, \ldots, m$),

is equivalent to (4).

**Branches Considered as Subequations**

Some of Gårding’s results from Section 2 can be summarized as follows. The ordered eigenvalues determine $m$ branches $F_k \equiv \{\lambda_k^\downarrow \geq 0\}$ of $\{M = 0\}$. Each $\partial F_k = \{\lambda_k^\downarrow = 0\}$
is contained in \( \{ M = 0 \} \), and \( F_k = \text{Int} F_k \) with \( \text{Int} F_k = \{ \lambda_k > 0 \} \). Each \( F_k \) is a cone, and the principal branch \( \Gamma = F_1 \) is a convex cone, which is a monotonicity cone for each of the other branches, i.e.,

\[
F_k + \Gamma \subset F_k \quad k = 1, \ldots, m.
\] (5.1)

**THEOREM 5.4.** Suppose that \( M \) is a Dirichlet-Gårding polynomial of degree \( m \) on \( \text{Sym}^2(\mathbb{R}^n) \). Then each branch \( F_k \), \( k = 1, \ldots, m \), is a subequation with dual subequation \( \tilde{F}_k = F_{m-k+1} \). Moreover, each branch is a cone.

**Proof.** Property (1b), that \( \lambda_k(A) = -\lambda_{m-k+1}^t(A) \) for the ordered eigenfunctions, implies that \( \tilde{F}_k = F_{m-k+1} \). Property (1a), that \( \lambda_k(tA) = t\lambda_k(A) \) for \( t \geq 0 \), implies \( F_k \) is a cone. Thus, as a special case of Theorem 4.15 we can solve the Dirichlet problem for each branch of the equation \( \{ M = 0 \} \).

**THEOREM 5.5.** Suppose that \( M \) is a Dirichlet-Gårding polynomial on \( \text{Sym}^2(\mathbb{R}^n) \). Let \( i \equiv \max\{k, n-k+1\} \). Then for each bounded domain \( \Omega \) with smooth strictly \( \Gamma \)-convex boundary, the Dirichlet problem for \( F_k \)-harmonic functions is uniquely solvable for all continuous boundary data.

**Remark 5.6.** (a) Fix \( c \in \mathbb{R} \) and replace \( F_k = \{ \lambda_k^t \geq 0 \} \) by \( F_k^c = \{ \lambda_k^t \geq c \} \). Both Theorem 5.4 and Theorem 5.5 remain true except for the fact that \( F_k^c \) is no longer a cone. Note that \( F_1^c \) remains a convex subequation.

(b) The principal branch \( F_1 = \Gamma \) can be perturbed to the convex cone subequation \( \Gamma_c = \{ A \in \Gamma : M(A) \geq c \} \).

Convexity follows from Corollary 2.13 (d) or (e).

**Examples of Dirichlet-Gårding Polynomials**

There are a number of geometrically interesting nonlinear equations that arise from the construction in Theorem 5.4, and for which Theorem 5.5 solves the Dirichlet problem.

**Example 5.7.** *(The Real Determinant).* Of course the fundamental example of a Dirichlet-Gårding polynomial is the polynomial on \( \text{Sym}^2(\mathbb{R}^n) \) given by

\[
M(A) = \text{det} A
\] (5.2)

where the \( M \)-eigenvalues of \( A \) are just the usual eigenvalues of \( A \) as a symmetric matrix. The corresponding \( F_1 \)-harmonic functions are convex solutions \( u \) of the homogeneous Monge-Ampère equation \( \text{det}\text{Hess} u = 0 \) (in the viscosity sense (cf. [HL_1], [HL_2])). The other branches \( F_k \), \( k = 2, \ldots, n \) lead to other branches of this equation. Theorem 5.5 says that the Dirichlet problem is uniquely solvable for \( F_k \)-harmonic functions on any domain which is strictly \( \Gamma \)-convex where \( i = \max\{k, n-k+1\} \).
Example 5.8. (The Complex and Quaternionic Determinant). Consider $C^n = (\mathbb{R}^{2n}, J)$ where $J : \mathbb{R}^{2n} \to \mathbb{R}^{2n}$ with $J^2 = -I$ is the standard almost complex structure. Then any $A \in \text{Sym}^2(\mathbb{R}^{2n})$ has a hermitian symmetric component

$$A_C \equiv \frac{1}{2}(A - JAJ)$$

which commutes with $J$. The eigenvalues of $A_C$, considered as a real $2n \times 2n$ symmetric matrix, occur in pairs, $\lambda_1, \lambda_1, \lambda_2, \lambda_2, \ldots, \lambda_n, \lambda_n$ with complex lines as eigenspaces, while $A_C$, considered as an $n \times n$ complex hermitian symmetric matrix, has $n$ real eigenvalues $\lambda_1(A_C) = \lambda_1, \ldots, \lambda_n(A_C) = \lambda_n$.

The complex determinant

$$\det_C(A_C) = \lambda_1(A_C) \cdots \lambda_n(A_C)$$

is a Dirichlet-Gårding polynomial in $A \in \text{Sym}^2(\mathbb{R}^{2n})$.

Similarly, one can consider quaternion $n$-space $H^n = (\mathbb{R}^{4n}, I, J, K)$, where $I, J, K$ satisfy the usual quaternion relations. Then any $A \in \text{Sym}^2(\mathbb{R}^{4n})$ has a quaternionic hermitian symmetric component

$$A_H \equiv \frac{1}{4}(A - IAI - JAJ - KAK)$$

which commutes with $I, J$ and $K$. The eigenvalues of $A$, considered as a real $4n \times 4n$ symmetric matrix, occur in multiples of four $\lambda_1, \lambda_1, \lambda_1, \lambda_1, \lambda_2, \lambda_2, \ldots, \lambda_n, \lambda_n$ with quaternion lines as eigenspaces, while $A_H$, considered as a quaternionic hermitian symmetric $n \times n$ matrix can be diagonalized under the action of $\text{Sp}_n \cdot \text{Sp}_1$ with $n$ real eigenvalues $\lambda_1(A_H) = \lambda_1, \ldots, \lambda_n(A_H) = \lambda_n$. The quaternion determinant

$$M(A) = \det_H(A_H) = \lambda_1(A_H) \cdots \lambda_n(A_H)$$

is a Dirichlet-Gårding polynomial in $A \in \text{Sym}^2(\mathbb{R}^{4n})$.

Example 5.9. (Lagrangian Harmonicity). This is a non-classical case. Consider $C^n = (\mathbb{R}^{2n}, J)$ as above, and for $A \in \text{Sym}^2(\mathbb{R}^{2n})$ define the skew hermitian component

$$A_{\text{skew}} \equiv \frac{1}{2}(A + JAJ)$$

which anti-commutes with $J$. The eigenvalues occur in opposite pairs $\pm \mu_1, \ldots, \pm \mu_n$ where each $\pm \mu_k$-eigenspace generates a complex line. Let $\tau = \frac{1}{2}\text{trace}_{\mathbb{R}} A$.

Proposition 5.10. The product

$$M_{\text{LAG}}(A) \equiv \prod_{2^n \text{ times}} (\tau \pm \mu_1 \pm \cdots \pm \mu_n)$$

taken over all sequences $\pm \cdots \pm$, is a Dirichlet-Gårding polynomial on $\text{Sym}^2(\mathbb{R}^{2n})$. 

33
More generally, for any $1 \leq p \leq n$, the product
\[
M(A) = \prod_{|I|=p} \left( \tau \pm \mu_{i_1} \pm \cdots \pm \mu_{i_p} \right)
\]
is a Dirichlet-Gårding polynomial. (See [HL3] for the proof.)

We shall refer to these four basic examples as the real, complex, quaternionic, and Lagrangian/Isotropic Monge-Ampère polynomials. Now we describe three methods of constructing a new Dirichlet-Gårding polynomial from a given one.

The first method decreases the degree of the Dirichlet-Gårding polynomial.

**Method 5.11. (Derivatives – The Elementary Symmetric Functions).** Given a Dirichlet-Gårding polynomial $M$ with Gårding cone $\Gamma$, for each $A_0 \in \Gamma$, the $k$th derivative $M^{(k)}$ in the direction $A_0$ is also a Dirichlet-Gårding polynomial. This is because $\Gamma_{M^{(k+1)}} \supset \Gamma_{M^{(k)}} \supset \cdots \supset \Gamma_{M}$, by Proposition 2.21, and so $\mathcal{P} \subset T_M$ implies $\mathcal{P} \subset \Gamma_{M^{(k)}}$. By (2.26) this construction is equivalent to taking the elementary symmetric functions of the $A_0$-eigenvalues (as functions on $\text{Sym}^2(\mathbb{R}^n)$).

This method can be applied, of course, to the real, complex, quaternionic, and Lagrangian/Isotropic Monge-Ampère polynomials.

**Note.** Different choices of $A \in \Gamma$ produce different Dirichlet-Gårding polynomials.

The second method increases the degree of the Dirichlet-Gårding polynomial.

**Method 5.12. (k-Fold Sums of Eigenvalues).** Suppose we are given a Dirichlet-Gårding polynomial $M$ on $\text{Sym}^2(\mathbb{R}^n)$ with Gårding cone $\Gamma$. Fix $A_0 \in \Gamma$ and consider the $A_0$-eigenvalue functions $\lambda_1(A), \ldots, \lambda_m(A)$. Then
\[
M_k(A) = \prod_{|I|=k} \left( \lambda_{i_1}(A) + \cdots + \lambda_{i_k}(A) \right) \quad A \in \text{Sym}^2(\mathbb{R}^n)
\]
defines a Dirichlet-Gårding polynomial of degree $\binom{m}{k}$ on $\text{Sym}^2(\mathbb{R}^n)$ with Gårding cone $\Gamma_k \supset \Gamma$ and $A_0$-eigenvalues functions
\[
\Lambda_I(A) = \frac{1}{k} \left( \lambda_{i_1}(A) + \cdots + \lambda_{i_k}(A) \right).
\]
This follows from Proposition 2.29 and Theorem 3.6.

**Note 5.13.**

(a) It is easy to see that $\Gamma = \Gamma_1 \subset \Gamma_2 \subset \cdots \subset \Gamma_n$.

(b) Any vector $w \in \text{Int}\mathbb{R}_+^m$ can replace $e = (1, \ldots, 1)$. We would then have:
\[
M_k(A) = \prod_{|I|=k} \left( w_{i_1} \lambda_{i_1}(A) + \cdots + w_{i_k} \lambda_{i_k}(A) \right) \quad A \in \text{Sym}^2(\mathbb{R}^n)
\]

The third method leaves the degree of the Dirichlet-Gårding polynomial fixed.
Method 5.14. \((\delta\text{-Uniformity})\). Define for \(\delta > 0\)

\[
\mathcal{P}_\delta = \{ A \in \text{Sym}^2(\mathbb{R}^n) : A + (\delta \text{tr} A) \cdot I \geq 0 \}.
\] (5.9)

Each \(\mathcal{P}_\delta\) is a convex cone subequation whose interior contains \(\mathcal{P}\). The family is conically-fundamental for \(\mathcal{P}\) in the following sense.

If \(F\) is any convex cone subequation with \(\mathcal{P} - \{0\} \subset \text{Int} F\),

then there exists \(\delta > 0\) such that \(\mathcal{P} \subset \mathcal{P}_\delta \subset F\) (5.10)

Definition 5.15. A subequation \(F \subset \text{Sym}^2(\mathbb{R}^n)\) is uniformly elliptic if for some \(\delta > 0\), \(F\) is \(\mathcal{P}_\delta\)-monotone, i.e.,

\[
F + \mathcal{P}_\delta \subset F.
\] (5.11)

Using (5.10) it is easy to show that our definition of uniform ellipticity is equivalent to any of the usual definitions.

Now for the third method. Suppose \(M\) is a Dirichlet-Gårding polynomial with Gårding cone \(\Gamma\). Choose \(A_0 \in \Gamma\). Let \(\lambda_1(A), ..., \lambda_m(A)\) denote the \(A_0\)-eigenvalue functions, and let \(\text{tr}\lambda(A) = \lambda_1(A) + \cdots + \lambda_m(A)\) denote the trace.

Theorem 5.16. The function

\[
M_\delta(A) = \prod_{j=1}^{m} (\lambda_j(A) + \delta \text{tr}(A))
\] (5.12)

is a Dirichlet-Gårding polynomial with uniformly elliptic branches \(F^\delta_k\) containing the branches \(F_k\) of \(\{M = 0\}\).

Proof. By Proposition 2.30, \(M_\delta\) is \(A_0\)-hyperbolic, and up to scale the \(A_0\)-eigenvalue functions are \(\Lambda_k(A) = \lambda_k(A) + \delta \text{tr}(A)\). Each branch \(F^\delta_k\) of \(\{M_\delta = 0\}\) is \(\Gamma_\delta\)-monotone by (5.1). It remains to show that \(\text{Int} \mathcal{P}_\delta \subset \Gamma_\delta\) for some \(\delta' > 0\). This follows from (5.10) with \(F = \mathcal{P}\) since \(\mathcal{P} - \{0\} \subset \Gamma - \{0\} \subset \text{Int} \mathcal{P}_\delta = \Gamma_\delta\). (Note that \(\text{tr}\lambda(A) > 0\) if \(A \in \Gamma\)).

Remark 5.17. The three methods of generating new DGPs, and hence new subequations for which Theorem 5.5 solves the Dirichlet problem, do not commute with each other. Thus combining these results creates a large number of new Dirichlet-Gårding polynomials.

Additional methods for generating subequations and solving the Dirichlet problem are investigated next.

Universal Eigenvalue Subequations

The branches \(F_k\) of \(\{M = 0\}\) are universally determined by requiring that:

\[
\lambda(A) \in E_k
\]

where \(E_k \equiv \{\lambda_k \geq 0\} = \{\lambda \in \mathbb{R}^m : \text{At least } m-k+1 \text{ of the } \lambda_j \text{ are } \geq 0\}\). Thus the subset \(E_k \subset \mathbb{R}^m\) universally determines the \(k\)th branch of \(\{M = 0\}\) for any Dirichlet-Gårding...
polynomial of degree \( m \) on \( \text{Sym}^2(\mathbb{R}^n) \). For example, \( E \) defined by \( \lambda_1 \geq 0, \ldots, \lambda_m \geq 0 \) is the universal Monge-Ampère subequation, and it induces an \( M \)-Monge-Ampère subequation for each Dirichlet-Gårding polynomial \( M \) of degree \( m \).

**Definition 5.18.** A closed symmetric subset \( E \) of \( \mathbb{R}^m \), with \( \emptyset \neq E \neq \mathbb{R}^m \), which is positive-orphant monotone, will be called a universal eigenvalue subequation.

If, in addition,

(a) \( E \) is convex, then \( E \) will be called a convex (universal) eigenvalue subequation.

(b) \( E \) is \((\mathbb{R}^m)^\delta\)-monotone for some \( \delta > 0 \), then \( E \) will be called a uniformly elliptic (universal) eigenvalue subequation.

The structure of universal eigenvalue subequations is described in Proposition 5.25 below. We leave to the reader a similar result for uniformly elliptic universal eigenvalue subequations.

**Theorem 5.19.** A universal eigenvalue subequation \( E \) on \( \mathbb{R}^m \) universally determines a subequation \( F_E \) on \( \mathbb{R}^n \) for each Dirichlet-Gårding polynomial \( M \) on \( \text{Sym}^2(\mathbb{R}^n) \) of degree \( m \) by setting

\[
F_E \equiv \{ A \in \text{Sym}^2(\mathbb{R}^n) : \lambda(A) \in E \} = \lambda^{-1}(E).
\]

Moreover,

\[
\tilde{F}_E = F_{\tilde{E}} \quad \text{and} \quad \tilde{F}_E = F_{\tilde{E}}
\]

Finally,

(a) If \( E \) is convex, then \( F_E \) is a convex subequation.

(b) If \( E \) is uniformly elliptic, then \( F_E \) is a uniformly elliptic subequation.

**Proof.** The important monotonicity result Theorem 3.6 implies that \( F_E \) is a subequation (utilizing Definitions 5.2 and 5.18). We leave (5.13) to the reader. Part (a) is Theorem 3.8 while for (b) Theorem 3.7 says that \( F_E \) is \( \Gamma_\delta \)-monotone. As noted in the proof of Theorem 5.16, this implies that \( F_E \) is uniformly elliptic. \( \Box \)

Because of the results proved in [HL1] (stated as Theorem 4.15 here) for each of the subequations \( F_E \) constructed in Theorem 5.18, the Dirichlet problem can be solved.

**Theorem 5.20.** Suppose that \( E \) is a universal eigenvalue subequation on \( \mathbb{R}^m \), and \( M \) is a Dirichlet-Gårding polynomial on \( \mathbb{R}^n \) of degree \( m \). Then the Dirichlet problem for the subequation \( F_E \) induced by \( E \) and \( M \) can be solved uniquely for all continuous boundary data on any domain with smooth boundary which is both \( \tilde{F}_E \) and \( \tilde{F}_{\tilde{E}} \) strictly convex.

**Examples of Universal Eigenvalue Subequations**

The first four examples of universal subequations \( E \) have already been discussed along with their induced subequations \( F_E \). In these examples \( E \) is a branch of an \( e \)-hyperbolic polynomial \( Q \) on \( \mathbb{R}^m \) whose Gårding cone \( \Gamma \) contains \( \mathbb{R}^m_+ \). Taking \( M \) to be
any Dirichlet-Gårding polynomial of degree $m$ and composing $Q$ with the eigenvalue map of $M$, one sees that Methods 5.10, 5.11 and 5.13 can now be considered special cases of Theorem 5.18.

**Example 5.21. (The Branches of the Universal Monge-Ampère Equation).** These are the subsets

$$E_k = \{ \lambda \in \mathbb{R}^m : \lambda_k^\uparrow \geq 0 \} \quad k = 1, ..., m.$$ 

which are the branches of the universal Monge-Ampère equation $Q(\lambda) = \lambda_1 \cdots \lambda_m$.

**Example 5.22. (The Branches of the Universal $p^{th}$ Elementary Symmetric Function).** These subsets $E \subset \mathbb{R}^m$ are defined by requiring that at least $k^* = p - k + 1$ of the $e$-eigenvalues of

$$Q(\lambda) = \sum_{|I| = p} \lambda_{i_1} \cdots \lambda_{i_p}$$

are $\geq 0$.

**Example 5.23. (The Universal Geometrically $p$-Convex Equation and its Branches).** Here the subsets $E$ of $\mathbb{R}^m$ are the branches of

$$Q(\lambda) = \prod_{|I| = p} (\lambda_{i_1} + \cdots + \lambda_{i_p})$$

defined by requiring at least $r$ of the $p$-fold sums $\lambda_{i_1} + \cdots + \lambda_{i_p}$ (these are $p$-times the $e$-eigenvalues of $Q$) to be $\geq 0$.

**Example 5.24. (The Universal $\delta$-Uniformly Elliptic Subequation).** Fix $\delta > 0$ and let $\text{tr} \lambda = \lambda \cdot e = \lambda_1 + \cdots + \lambda_m$. Set

$$Q_\delta(\lambda) = \prod_{k=1}^m (\lambda_k + \delta \text{tr} \lambda)$$

The branches of $\{Q_\delta = 0\}$ defined by requiring at least $k^* = m - k + 1$ of the eigenvalues $\Lambda_j = \lambda_j + \delta \text{tr} \lambda, \ j = 1, ..., m$ to be $\geq 0$, are universal uniformly elliptic subequations. Note that as $\delta > 0$ varies, the principal branches $(\mathbb{R}^m_+)\delta$ form a conically-fundamental neighborhood system for $\mathbb{R}^m_+ = \mathbb{R}^m_+$. The following provides a classification of universal subequations.

**Proposition 5.25.** A subset $E \subset \mathbb{R}^m$ is a universal eigenvalue subequation if and only if there exists a $\| \cdot \|^{\pm}$-Lipschitz symmetric function $f$ on the hyperplane normal to $e$ with

$$E = \{ \lambda + te : \lambda \cdot e = 0 \ \text{and} \ t \geq f(\lambda) \}$$

**Proof.** See Example 3.4.
Example 5.26. (Using Functions to Construct Subequations). For simplicity we first consider the universal case. Suppose

\[ E_{c_1} = \{ \lambda : f_1(\lambda) \geq c_1 \} \quad \text{and} \quad E_{c_2} = \{ \lambda : f_2(\lambda) \geq c_2 \}. \]

The description of the set \( E_c = \{ \lambda : f_1(\lambda) + f_2(\lambda) \geq c_2 \} \) as \( \bigcup_{c_1 + c_2 \geq c} (E_{c_1} \cap E_{c_2}) \) is awkward. Similarly, if \( f_1 \geq 0 \) and \( f_2 \geq 0 \), the set \( E_c = \{ \lambda : f_1(\lambda)f_2(\lambda) \geq c \} \) is awkward to describe. Consequently in describing examples of universal eigenvalue subequations it is useful to state an obvious result.

Lemma 5.27. Suppose that \( f(\lambda) \) is a continuous symmetric function defined on an open symmetric subset of \( \mathbb{R}^m \). Choose \( c \in \mathbb{R} \), set \( E_c = \{ \lambda : f(\lambda) \geq c \} \), and assume \( \emptyset \neq E_c \neq \mathbb{R}^m \).

If \( f \) is non-decreasing in each variable, then \( E_c \) is a universal subequation.

If, in addition, \( f \) is concave, then \( E_c \) is a convex subequation.

Example 5.28. (Special Lagrangian Type). Suppose \( \varphi : \mathbb{R} \to \mathbb{R} \) is strictly increasing. For each \( c \in \mathbb{R} \)

\[ E_c = \left\{ \lambda \in \mathbb{R}^m : \sum_{k=1}^{m} \varphi(\lambda_k) \geq c \right\} \]

is a universal eigenvalue subequation. Taking \( \varphi : \mathbb{R} \to (-\frac{\pi}{2}, \frac{\pi}{2}) \) to be \( \varphi(t) = \arctan(t) \), we obtain the universal special Lagrangian subequation:

\[ E_c \equiv \left\{ \lambda \in \mathbb{R}^m : \sum_{k=1}^{m} \arctan \lambda_k \geq c \right\}, \quad c \in \left( -\frac{m\pi}{2}, \frac{m\pi}{2} \right). \]

The arctangent function is concave on \( t > 0 \), but convex on \( t < 0 \). Consequently, in order for \( E_c \) to be convex, the condition \( \sum_{k=1}^{m} \arctan \lambda_k \geq c \) must imply that each \( \lambda_k \geq 0 \). This proves easily that \( E_c \) is convex if \( c \geq \frac{(m-1)\pi}{2} \). A detailed calculation due to Yuan [Y, Lemma 2.1] shows that

\[ E_c \text{ is convex} \iff c \geq \frac{(m-2)\pi}{2} \tag{5.14} \]

Note that the function \( f \) in the structure Theorem 5.25 is difficult to describe for this set \( E_c \).

Example 5.29. (Krylov Type). First note that by Theorem 2.9 for any \( a \)-hyperbolic polynomial \( p \) on a vector space \( V \)

\[ -\frac{p'_{a}(x)}{p(x)} = -\sum_{k=1}^{m} \frac{1}{\lambda_{a}^{k}(x)} \quad \text{is } \Gamma - \text{monotone on } \Gamma, \tag{5.15} \]
i.e., strictly increasing in $t$ on lines $x + tb$ (with $x, b \in \Gamma$ and $t > 0$). Equivalently,

$$\frac{p(x)}{p'(x)}$$

is $\Gamma$-monotone on $\Gamma$. Since each $p^{(k)}(x)$ is positive on $\Gamma$, this implies that

$$p(x) p^{(k)}(x) = p(x) p^{(1)}(x) \cdots p^{(k-1)}(x)$$

is also $\Gamma$-monotone on $\Gamma$. Equivalently, each function $-p^{(k)}(x)/p(x)$ is $\Gamma$-monotone on $\Gamma$. Consequently, we have that for all $c_0, \ldots, c_{m-1} \geq 0$, the set

$$F = \left\{ A \in \Gamma(p) : p(A) - \sum_{k=0}^{m-1} c_k rp^{(k)}(A) \geq 0 \right\} \quad (5.16)$$

is a subequation for any Dirichlet-Gårding polynomial of degree $m$ on $\text{Sym}^2(\mathbb{R}^n)$.

Obviously there are many other ways to use (5.15) to construct subequations. In Krylov [K], the Dirichlet problem was solved for $F$ defined by (5.16) when $p(A) = \det A$ is the determinant.

Using the following lemma, one can show that $F$ is a convex subequation.

**Lemma 5.30.** Suppose that $p$ is $a$-hyperbolic on $V$. Then on the Gårding cone $\Gamma$ the function $p(x)/p'(x)$ is concave.

**Proof.** Set $f(x) = p(x)/p'_a(x)$ and note that $f$ is homogeneous of degree one, so that (2.3)$'$ can be used. By Theorem 3.6 it suffices to consider the universal case

$$p(x) = x_1 \cdots x_m \quad \text{with} \quad a = (1, \ldots, 1).$$

Then $f(x) = p(x)/p'_a(x) = 1/\left( \sum \frac{1}{x_k} \right)$, and $f'_x(y) = (\sum \frac{x_k}{y_k})^2$ so that (2.3)$'$ becomes

$$\left( \sum \frac{1}{y_k} \right)^2 \leq \left( \sum \frac{1}{x_k} \right) \left( \sum \frac{x_k}{y_k^2} \right)$$

which is the Cauchy-Schwartz inequality where $a_k = \frac{1}{\sqrt{x_k}}$ and $b_k = \frac{\sqrt{x_k}}{y_k}$. $\blacksquare$

The fact that $F$ is a convex subequation is an immediate consequence of the next result.

**Corollary 5.31.**

$$\log \frac{p^{(k)}(x)}{p(x)}, \quad \text{and therefore also} \quad \frac{p^{(k)}(x)}{p(x)}, \quad \text{is convex on} \quad \Gamma.$$
Proof. Applying the convex increasing function \( \varphi(t) = -\log(-t), t < 0 \), to the convex function \( -\frac{p(x)}{p'(x)} \) shows that \( \log \frac{p'(x)}{p(x)} \) is convex. Hence \( \log \frac{p'(x)}{p(x)} = \sum_{j=1}^{k} \log \frac{p(j)}{p(j-1)}(x) \) is convex.

6. The Dirichlet Problem on Riemannian Manifolds

Many of the equations discussed above can be carried over to Riemannian manifolds, and existence and uniqueness results for the Dirichlet problem have been established in this context in [HL2]. An essential ingredient for obtaining results in this general setting centers on the concept of a monotonicity cone. The discussion above fits neatly into this theory since for any \( I \)-hyperbolic polynomial on \( \text{Sym}^2(\mathbb{R}^n) \), the closed Gårding cone is a monotonicity cone for each of the branches \( F_k = \{ \lambda_k \geq 0 \} \). We give here a brief sketch of these ideas.

Let \( X \) be a Riemannian manifold and recall that any \( u \in C^2(X) \) has a well-defined Riemannian Hessian given by

\[
(Hess u)(V,W) \equiv VWu - (\nabla_V W)u
\]

for vector fields \( V \) and \( W \), where \( \nabla \) is the Levi-Civita connection. This defines a symmetric 2-form on \( TX \), that is, a section \( Hess u \) of \( \text{Sym}^2(T^*X) \).

Suppose now that \( F \subset \text{Sym}^2(T^*X) \) is a closed subset satisfying the positivity condition \( F + \mathcal{P} \subset F \) where \( \mathcal{P} = \{ A \in \text{Sym}^2(T^*X) : A \geq 0 \} \). Then a function \( u \in C^2(X) \) is said to be \( F \)-subharmonic if \( Hess_x u \in F \) for all \( x \in X \). This notion extends to any \( u \in \text{USC}(X) \) essentially as in Definition 4.8 above. With this understood, the formulation given in Section 4 of the Dirichlet problem for a domain \( \Omega \subset X \) and the formulation of strict \( F \)-convexity for \( \partial \Omega \) carry over to this setting.

However, the global nature of the problem requires a further global hypothesis before analogues of Theorem 4.15 can be established. Let \( M \subset \text{Sym}^2(T^*X) \) be a closed subset such that \( M + \mathcal{P} \subset M \) and each fibre \( M_x \) is a convex cone with vertex at the origin. Then \( M \) is called a **monotonicity cone for \( F \)** if under point-wise sum,

\[
F + M \subset F.
\]

The equations of interest here are those which are, in a sense, “universal” in geometry. We now make this precise. Fix a closed subset \( F \subset \text{Sym}^2(\mathbb{R}^n) \) with \( F + \mathcal{P} \subset F \) and suppose that

\[
g(F) = F \quad \text{for all } g \in O_n \tag{6.2}
\]

where \( O_n \) acts on \( \text{Sym}^2(\mathbb{R}^n) \) in the standard way. Then \( F \) naturally determines a subequation \( F \) on any Riemannian manifold \( X \) as follows. Let \( e_1, \ldots, e_n \) be an orthonormal tangent frame field defined on an open set \( U \subset X \). This determines a trivialization

\[
\text{Sym}^2(T^*U) \xrightarrow{\varphi_U} U \times \text{Sym}^2(\mathbb{R}^n), \tag{6.3}
\]

40
and we define
\[ F \cap \text{Sym}^2(T^*U) \equiv \varphi_U^{-1}(U \times F). \] (6.4)

By the invariance (6.2) this set is independent of the choice of orthonormal frame field. The resulting subequation
\[ F \subset \text{Sym}^2(T^*X) \]
is said to be **universally determined** by the constant coefficient subequation \( F \).

This construction can be generalized. For \( F \subset \text{Sym}^2(\mathbb{R}^n) \) as above, let
\[ G = G(F) \equiv \{ g \in O_n : g(F) = F \}, \]
and suppose \( X \) is provided with a **topological \( G \) structure**. This means that there is given a distinguished covering of \( X \) by open sets \( \{ U_\alpha \} \) with an orthonormal frame field \( e^\alpha = (e^\alpha_1, ..., e^\alpha_n) \) on each \( U_\alpha \) so that the each change of framing has values in \( G \), i.e.,
\[ g_{\alpha \beta} : U_\alpha \cap U_\beta \to G \subset O_n. \]

Then in the manner above, \( F \) universally determines a subequation \( F \subset J^2(X) \) on any riemannian manifold with a topological \( G \)-structure.

For example any almost complex manifold with a compatible riemannian metric (i.e., for which \( J \) is point-wise orthogonal) carries a topological \( U_n \)-structure.

The following is one of the results proved in [HL2].

**THEOREM 6.1.** Let \( X \) be a riemannian manifold with a topological \( G \)-structure. Let \( F \subset \text{Sym}^2(\mathbb{R}^n) \) be a subequation with monotonicity cone \( M \subset \text{Sym}^2(\mathbb{R}^n) \) and suppose both are \( G \)-invariant. Let \( F, M \subset J^2(X) \) be the subequations on \( X \) universally determined by \( F \) and \( M \).

Suppose \( X \) carries a \( C^2 \) strictly \( M \)-subharmonic function.

Then for each bounded domain \( \Omega \subset \subset X \) with smooth boundary \( \partial \Omega \) which is both \( \overline{F} \) and \( \overline{M} \) strictly convex, the Dirichlet problem is uniquely solvable for all continuous boundary data. That is, for each \( \varphi \in C(\partial \Omega) \), there exists a unique \( u \in C(\overline{\Omega}) \) satisfying:

1. \( u \) is \( F \)-harmonic on \( \Omega \), and
2. \( u = \varphi \) on \( \partial \Omega \).

The constructions above give many interesting examples of such universal equations in geometry. For any \( G \)-invariant Dirichlet-Gårding polynomial, the closed Gårding cone \( F_1 \) is a monotonicity cone for every branch \( F_k \) and all branches are \( G \)-invariant. All further constructions can be carried over as well.

**Appendix A. An Algebraic Description of the Branches**

Suppose \( p(x) \) is \( a \)-hyperbolic of degree \( m \) as in Section 2. Each of the branches
\[ F_m \supset \cdots \supset F_1 \]

41
of \( \{ p = 0 \} \) can be described by polynomial inequalities involving the elementary symmetric functions. Normalize so that \( p(a) = 1 \) and recall from (2.20) that

\[
p(ta + x) = \prod_{k=1}^{m} (t + \lambda_k(x)) = t^m + \sigma_1(x)t^{m-1} + \cdots + \sigma_m(x)
\]

where

\[
\sigma_k(x) = \sum_{i_1 < \cdots < i_k} \lambda_{i_1}(x) \cdots \lambda_{i_k}(x)
\]

is the \( k \)th elementary symmetric function of the \( a \)-eigenvalues of \( x \). Set \( \sigma_0(x) \equiv 1 \).

Each \( \sigma_k(x) \) is a homogeneous polynomial in \( x \) of degree \( k \), which is \( a \)-hyperbolic as noted in (3) of Section 2.

Now suppose that \( f(t) = \prod_{k=1}^{m} (t + \lambda_k) = t^m + \sigma_1 t^{m-1} + \cdots + \sigma_m \) is any monic polynomial with real roots. Let \( E^+ \) denote the number of \( \lambda_k \geq 0 \). Let \( \text{Var}(\sigma) \) denote the total number of strict consecutive sign changes in the signs of \( \sigma = (\sigma_0, \sigma_1, \ldots, \sigma_m) \) where \( \sigma_0 = 1 \). By definition strict means first drop all zeros in \( \sigma \) and then compute the number of consecutive sign changes in the remaining tuple of real numbers. The classical Descartes rule of signs is the statement that

\[
E^+ + \text{Var}(\sigma) = m
\]

(A.2)

**Lemma A.1.** The \( k \)th branch \( F_k \) of \( \{ p = 0 \} \) is given by \( F_k = \{ x : \text{Var}(\sigma(x)) \leq k-1 \} \).

For example, \( F_1(M) \) is defined by

\[
\sigma_1(x) \geq 0, \ldots, \sigma_m(x) \geq 0
\]

(A.3)

since \( \text{Var}(\sigma) \leq 0 \) if and only if \( \sigma_1 \geq 0, \ldots, \sigma_m \geq 0 \).

**Proof.** Using the ordered \( a \)-eigenvalues of \( x \), the \( k \)th branch \( F_k \) of \( \{ p = 0 \} \) is defined by \( \lambda_k(x) \geq 0 \). or equivalently by the condition

\[
E^+(x) \geq m - k + 1.
\]

By Descarte’s rule of signs (A.2), this is equivalent to \( \text{Var}(\sigma(x)) \leq k - 1 \).

**Corollary A.2. (Algebraic description of the branches).** Set \( \epsilon = (\epsilon_0, \ldots, \epsilon_m) \) with \( \epsilon_0 = 1 \) and each \( \epsilon_j = \pm 1 \). Define \( F^\epsilon \) by the conditions

\[
\epsilon_1 \sigma_1(x) \geq 0, \cdots, \epsilon_m \sigma_m(x) \geq 0.
\]

(A.4)
Then
\[ F_k = \bigcup_{\text{Var}(\epsilon) \leq k-1} F^\epsilon. \]  
(A.5)

**Example A.3.** Consider the polynomial \( p(x, y, z) = \frac{1}{3}(xy + xz + yz) \) in \( \mathbb{R}^3 \) and set \( a = (1, 1, 1) \). Then
\[ p(ta + x) = t^2 + \frac{2}{3}(x + y + z)t + \frac{1}{3}(xy + xz + yz) = t^2 + \sigma_1 t + \sigma_2. \]

One easily computes that \( \{\sigma_2 \geq 0\} = C \cup (-C) \) where \( C \) is the convex circular cone with base \( B = \{x + y + z = 1\} \cap \{x^2 + y^2 + z^2 \leq 1\} \). The hyperplane \( \{\sigma_1 = 0\} \) divides the set \( \{\sigma_2 \geq 0\} \) into the two pieces \( C \) and \( -C \). The decompositions in Corollary A.2 are
\[ F_1 = C = F^{(1,1,1)} \quad \text{and} \quad F_2 = \sim (-C) = F^{(1,1,1)} \cup F^{(1,-1,-1)} \cup F^{(1,1,-1)} \]

### Appendix B. Gurvits’ Inequality

Gårding’s classical inequality and the recent improvement by Gurvits are derived in this appendix. We present the proofs in a way that emphasizes the parallels. Suppose that \( p \) is an \( a \)-hyperbolic polynomial of degree \( m \), and let \( \lambda_1(x), ..., \lambda_m(x) \) denote the \( a \)-eigenvalues of \( x \in V \). Elementary Property (3) says that
\[ p(a + tb) = p(a) \prod_{k=1}^{m} (1 + t\lambda^k(a)(b)) \quad \forall t \in \mathbb{R}, b \in V. \]  
(B.1)

and
\[ p'_a(a) = p(a) \sum_{k=1}^{m} \lambda^k(a)(b). \]  
(B.2)

If \( \lambda_1, ..., \lambda_m > 0 \), then the classical inequality between the geometric and arithmetic means says that
\[ \prod_{k=1}^{m} (1 + t\lambda_k) \leq \left(1 + \frac{\sum\lambda_k}{m} t\right)^m \quad \text{with equality } \iff \lambda_1 = \cdots = \lambda_m. \]  
(B.3)

Applying (B.3) to (B.1) and using (B.2) to substitute for \( \sum\lambda_k(b) \), proves the following inequality.

**Lemma B.1.** Suppose \( p \) is an \( a \)-hyperbolic polynomial of degree \( m \) and \( b \in \Gamma(p) \). Then for \( 0 < t < \infty \)
\[ p(a + tb) \leq p(a) \left(1 + \frac{p'_a(a)}{mp(a)} t\right)^m \]  
(B.4)
Equality holds if and only if one of the following equivalencies holds:

(i) \( \lambda_1(b) = \cdots = \lambda_m(b) \).

(ii) \( a \) and \( b \) are proportional module the edge \( E(p) \).

(iii) \( p(sa + tb) = (\alpha s + \beta t)^m \) for some \( \alpha > 0, \beta > 0 \).

**Proof that (i) \( \iff \) (iii).** Use formula (2.1)' for \( p(sa + tb) \).

**Proof that (i) \( \iff \) (ii).** Recall (Theorem 2.3(a)) that the edge equals the null set of \( p \). By Property (2), \( \lambda_k(b - \mu a) = \lambda_k(b) - \mu \). This proves that \( \lambda_k(b) = \mu \) for all \( k \) \( \iff \) \( b - \mu a \in \text{Edge}(p) \). \( \square \) \hspace{1cm} (B.5)

Gårding’s inequality follows from (B.4) by dividing both sides by \( t^m \) and taking infimums, which occur at \( t = \infty \) for both sides.

**Proposition B.2. (Gårding).** For all \( a, b \in \Gamma(p) \) one has

\[
p(b) = \inf_{t>0} \frac{1}{t^m} p(a + tb) \leq p(a)^{1-m} \left( \frac{1}{m} p_b'(a) \right)^m \tag{B.6}
\]

with equality as in Lemma B.1.

Gurvits’ inequality follows from (B.4) by dividing both sides by \( t \) and taking infimums. If equality occurs, then the infimums must occur at the same point \( t \), and at this point \( t \), equality must also occur in (B.4). This establishes the equality statement in the next result.

**Proposition B.3. (Gurvits).** Assume \( m \geq 2 \). For all \( a, b \in \Gamma(p) \)

\[
\frac{(m-1)^{m-1}}{m^m} \inf_{t>0} \frac{p(a + tb)}{t} \leq \frac{1}{m} p'_b(a) \tag{B.7}
\]

with equality the same as in Lemma B.1.

**Proof.** By (B.4) for each \( t > 0 \)

\[
\frac{p(a + tb)}{t} \leq p(a) \left( 1 + \frac{\alpha}{m} \right)^m \tag{B.8}
\]

with \( \alpha = \frac{p'_b(a)}{p(a)} \).

The function \( f(t) \equiv \frac{1}{t} (1 + \frac{\alpha}{m})^m \) on the interval \( 0 < t < \infty \) blows up at the endpoints and has a single critical point at \( t = \frac{m-1}{m} \frac{1}{\alpha} = \frac{m}{m-1} \frac{p(a)}{p'_b(a)} \) with critical value \( (\frac{m}{m-1})^m \alpha = \frac{(m-1)^{m-1}}{m^m} \frac{1}{\alpha} \frac{1}{m} p'_b(a) \). This proves the inequality (B.7). \( \square \)

Gårding’s full inequality follows from the special case (B.6) by induction.

**THEOREM B.4. (Gårding).** Suppose that \( p \) is \( a \)-hyperbolic of degree \( m \) and \( b_1, \ldots, b_m \in \Gamma(p) \). Then

\[
p(b_1) \frac{1}{m} \cdots p(b_m) \frac{1}{m} \leq \frac{1}{m!} p_{b_1}^{(m)} \cdots b_m^{(m)}. \tag{B.9}
\]
with equality if and only if one of the following equivalencies holds:

(i) \( b_1, \ldots, b_m \) are pairwise proportional modulo the edge \( E(p) \).

(ii) \( \text{Edge}(p) \cap W \) has codimension one in \( W \equiv \text{span} \{ b_1, \ldots, b_m \} \).

(iii) \( p(t_1 b_1 + \cdots + t_m b_m) = (\alpha_1 t_1 + \cdots + \alpha_m t_m)^m \) for some \( \alpha_1, \ldots, \alpha_m > 0 \).

**Proof.** Induction can be employed because \( p'_b \) is also \( a \)-hyperbolic with \( \Gamma(p'_b) \supset \Gamma(p) \) and \( \text{Edge}(p'_b) = \text{Edge}(p) \). (See Propositions 2.21 and 2.32.) Employing (B.6)' with \( a = b_j, \ 1 \leq j \leq m - 1 \) and with \( b = b_m \) we have

\[
p(b_j)^{\frac{m-1}{m}} p(b_m)^{\frac{1}{m}} \leq \frac{1}{m} p'_{b_m}(b_j) \quad \text{for } j = 1, \ldots, m - 1.
\]

Taking the product of both sides over \( j = 1, \ldots, m - 1 \) yields

\[
p(b_1)^{\frac{m-1}{m}} \cdots p(b_m)^{\frac{m-1}{m}} \leq \frac{1}{m^{m-1}} p'_{b_m}(b_1) \cdots p'_{b_m}(b_{m-1}) \quad (B.10)
\]

The induction hypothesis applied to the polynomial \( p'_{b_m} \) says that

\[
p'_{b_m}(b_1)^{\frac{1}{m-1}} \cdots p'_{b_m}(b_{m-1})^{\frac{1}{m-1}} \leq \frac{1}{(m-1)!} p^{(m)}_{1 \ldots m} \quad (B.11)
\]

Taking the \((m-1)\)st root of both sides of (B.10) and combining it with (B.11) proves (B.9). The equality statement follows easily from Lemma B.1. \( \blacksquare \)

**Remark B.5.** If \( a, b_1, \ldots, b_m \in V \), then the \( m \)-fold directional derivative in the directions \( b_1, \ldots, b_m \) is a constant independent of \( a \). Let \( \overline{p} \) denote the completely polarized form of \( p \). Then

\[
\frac{1}{m!} p^{(m)}_{1 \ldots m} = \frac{1}{m!} \frac{\partial^m}{\partial t_1 \cdots \partial t_m} p(a + t_1 b_1 + \cdots + t_m b_m) \bigg|_{t=0} = \overline{p}(b_1, \ldots, b_m) \quad (B.12)
\]

If \( q \) is a homogeneous polynomial of degree \( k \), then \( q'_b(a) = kq(a) \) for any direction \( a \in V \). Setting \( b_{k+1} = \cdots = b_m = a \in \Gamma(p) \) in Gårding’s inequality (B.9) yields

\[
p(b_1)^{\frac{1}{m}} \cdots p(b_k)^{\frac{1}{m}} p(a)^{\frac{m-k}{m}} \leq \frac{1}{k!} p^{(k)}_{b_1, \ldots, b_k} (a). \quad (B.13)
\]

Gurvits’ full inequality follow from the special case (B.7) by induction.

**THEOREM B.6.** (Gurvits). Suppose that \( p \) is \( a \)-hyperbolic and \( b_1, \ldots, b_m \in \Gamma(p) \). Then

\[
\frac{1}{m^m} \text{Cap}(p) \overset{\text{def}}{=} \frac{1}{m^m} \inf_{t_1, \ldots, t_m > 0} \frac{p(t_1 b_1 + \cdots + t_m b_m)}{t_1 \cdots t_m} \leq \frac{1}{m!} p^{(m)}_{b_1, \ldots, b_m} \quad (B.14)
\]

with equality holding exactly as in Gårding’s Theorem.
Proof. We use Lemma B.3 repeatedly.

\[
\frac{1}{m^m} \inf_{t_1 \leq t_m > 0} \frac{p(t_1 b_1 + \cdots + t_m b_m)}{t_1 \cdots t_m} \leq \frac{1}{m(m-1)^{m-1}} \inf_{t_{m-1} > 0} \frac{p_{b_m}^{(1)}(t_1 b_1 + \cdots + t_m b_{m-1})}{t_1 \cdots t_{m-1}}
\]

and

\[
\frac{1}{m(m-1)^{m-1}} \inf_{t_{m-1} > 0} \frac{p_{b_m}^{(1)}(t_1 b_1 + \cdots + t_m b_{m-1})}{t_1 \cdots t_{m-1}} \leq \frac{1}{(m-1)(m-2)^{m-2}} \inf_{t_{m-2} > 0} \frac{p_{b_m}^{(2)}(t_1 b_1 + \cdots + t_m b_{m-2})}{t_1 \cdots t_{m-2}}
\]

eetc., proves that

\[
\frac{1}{m^m} \inf_{t_1, \ldots, t_m > 0} \frac{p(t_1 b_1 + \cdots + t_m b_m)}{t_1 \cdots t_m} \leq \frac{1}{m!} p_{b_1, \ldots, b_m}^{(m)}(t_1 b_1)
\]

which equals \(\frac{1}{m!} p_{b_1, \ldots, b_m}^{(m-1)}\) since \(p_{b_1, \ldots, b_m}^{(m-1)}\) is homogeneous of degree 1. □

Remark B.7. (Capacity). The capacity of \(p\) with respect to \(b_1, \ldots, b_m \in \Gamma(p)\) is defined by

\[
\text{Cap}_{b_1, \ldots, b_m}(p) = \inf_{t_1, \ldots, t_m > 0} \frac{p(t_1 b_1 + \cdots + t_m b_m)}{t_1 \cdots t_m}
\]

The inductive step above can be written as

\[
\frac{1}{k^k} \text{Cap}_{b_1, \ldots, b_k}(p_{b_{k+1}, \ldots, b_m}^{(m-k)}) \leq \frac{1}{k(k-1)^{k-1}} \text{Cap}_{b_1, \ldots, b_{k-1}}(p_{b_k, \ldots, b_m}^{(m-k+1)}) \quad (B.15)
\]

Remark B.8 (Gurvits Refines/Improves Gårding). Suppose \(p\) is \(\alpha\)-hyperbolic and \(b_1, \ldots, b_m \in \Gamma(p)\).

\[
p(b_1)^{\frac{1}{m}} \cdots p(b_m)^{\frac{1}{m}} \leq \frac{1}{m^m} \inf_{x_1, \ldots, x_m > 0} \frac{p(x_1 b_1 + \cdots + x_m b_m)}{x_1 \cdots x_m} \overset{\text{def}}{=} \frac{1}{m^m} \text{Cap}(p) \quad (B.16)
\]

Proof. Using homogeneity and replacing \(b_j\) by \(x_j b_j\) the inequality becomes

\[
p(b_1)^{\frac{1}{m}} \cdots p(b_m)^{\frac{1}{m}} \leq \frac{1}{m^m} p(b_1 + \cdots + b_m).
\]

(B.16)' We may assume that \(p(b_j) > 0, j = 1, \ldots, m\), i.e., \(b_1, \ldots, b_m \in \Gamma(p)\).

Now (B.16)' follows from the classical geometric-arithmetic mean inequality:

\[
p(b_1)^{\frac{1}{m}} \cdots p(b_m)^{\frac{1}{m}} \leq \left[ \frac{p(b_1)^{\frac{1}{m}} + \cdots + p(b_m)^{\frac{1}{m}}}{m} \right]^m
\]

and the concavity of \(p^{\frac{1}{m}}\):

\[
p(b_1)^{\frac{1}{m}} + \cdots + p(b_m)^{\frac{1}{m}} \leq p(b_1 + \cdots + b_m)^{\frac{1}{m}}
\]

Remark B.9. Note that the L.H.S. in the Gårding inequality vanishes if any one of \(b_1, \ldots, b_m\) are on the boundary of \(\Gamma(p)\). However, the \((b_1, \ldots, b_m)\)-capacity of \(p\) occurring in the Gurvits inequality may not be zero. See [Gur\textsubscript{1}] for a more general upper bound result for the \((b_1, \ldots, b_m)\)-capacity which allows for degeneracies.
