A POSTERIORI ERROR ESTIMATES FOR FINITE ELEMENT DISCRETIZATIONS OF TIME-HARMONIC MAXWELL’S EQUATIONS COUPLED WITH A NON-LOCAL HYDRODYNAMIC DRAUDE MODEL

T. CHAUMONT-FRELET†‡, S. LANTERI†‡, AND P. VEGA†

Abstract. We consider finite element discretizations of Maxwell’s equations coupled with a non-local hydrodynamic Drude model that accurately accounts for electron motions in metallic nanostructures. Specifically, we focus on a posteriori error estimation and mesh adaptivity, which is of particular interest since the electromagnetic field usually exhibits strongly localized features near the interface between metals and their surrounding media. We propose a novel residual-based error estimator that is shown to be reliable and efficient. We also present a set of numerical examples where the estimator drives a mesh adaptive process. These examples highlight the quality of the proposed estimator, and the potential computational savings offered by mesh adaptivity.

Key words. A posteriori error estimates; Finite element methods; Maxwell’s equations; Non-local hydrodynamic Drude model; Plasmonics

1. Introduction

The interaction of light with metallic nanostructures gives rise to so-called plasmonic waves that are due to collective oscillations of conduction band electrons in the metal, and typically concentrate at the interface between the nanostructure and the surrounding medium. These unusual properties allow an extraordinary level of light manipulation at the nanoscale [17], with applications in waveguiding [21], lasing [23], near-field scanning microscopy [20], ultrasensitive sensing [24] and energy harvesting [5].

Electromagnetic fields penetrate in noble metals up to 25 nm whatever the wavelength. Small metallic nanostructures actually contains a plasma, whose electromagnetic response is in opposition to the incoming field, generating plasmonic waves. While this effect is negligible when considering large structures, metals cannot be considered to be perfectly conducting at the nanoscale, and valence electrons have to be modeled as a gas [17], leading to dispersive material laws.

In this work, we focus on the time-harmonic setting where the electromagnetic field oscillates in time at a prescribed frequency \( \omega > 0 \). In this context, the Drude model [29] is a fairly simple yet efficient oscillator model for free electrons in metals. Standard Maxwell’s equations are employed in the metal to describe the propagation of the electric field \( \mathbf{E} \),

\[
-\omega^2 \varepsilon_0 \mathbf{E} + \nabla \times \left( \mu_0^{-1} \nabla \times \mathbf{E} \right) = \mathbf{o}
\]

but the permittivity

\[
\varepsilon_d := \left( 1 - \frac{\omega_p^2}{i \gamma \omega + \omega^2} \right) \varepsilon_0
\]

\[\]
becomes a complex-valued function of the frequency, with a negative real part at optical frequencies. Above, $\varepsilon_0$ and $\mu_0$ respectively denote the vacuum electric permittivity and magnetic permeability. $\omega_P$ and $\gamma$ are the so-called “plasma” and “collision” frequencies of the metal under consideration. Although the Drude model performs well in most cases, it becomes inaccurate when the size of the considered nanostructure decreases beyond approximately 10 nm. Then, a possible extension is the so-called non-local hydrodynamic Drude (NHD) model [22], where the electron gas is treated as a fluid. Compared to the “local” Drude model for free electrons, this hydrodynamic approach accounts for the Fermi velocity $\vartheta_F$ of the electrons via an additional parameter $\beta^2 := (3/5)\vartheta_F^2$, namely

\[
\begin{align*}
-\omega^2\varepsilon_0 E + \nabla \times (\mu_0^{-1} \nabla \times E) + i\omega J &= 0, \\
-\omega^2 J - i\omega\gamma J - \nabla (\beta^2 \nabla \cdot J) - i\omega\omega_P^2\varepsilon_0 E &= 0,
\end{align*}
\]

where the motion of the electrons is now explicitly modeled through the velocity field $J$. Notice that setting $\beta := 0$, (1.2) reduces to (1.1). Thanks to its relatively simple form and the successful interpretation of observable non-local effects [10], the NHD model has become a quite popular approach in the study of optical properties of metallic nanostructures.

The above considerations have naturally led to an increasing interest for efficient numerical discretizations of Maxwell’s equations coupled with NHD model (1.2) in metallic nanostructures. Several approaches have been considered, including boundary integral equations [28], discontinuous Galerkin schemes [15, 27] and finite element methods [14, 16, 25]. Here, we focus on finite element discretizations, which have the advantage to easily handle heterogeneous media as compared to integral equations, while being simpler to implement and analyze than discontinuous Galerkin schemes. The ability to work on unstructured meshes not only permits to deal with arbitrary geometries, but it also allows for local mesh refinements. Such local refinements increase the accuracy in those areas where the solution exhibit a complex behavior at a reduced cost, and seem of particular interest in the context of nanoplasmonics, since plasmons are in general strongly localized. Here, we thus focus on the design and analysis of a posteriori error estimators, and their ability to drive mesh adaptive algorithms [2, 26].

Our main contributions are threefold. First, we propose a novel a posteriori error estimator for finite element discretizations of the Maxwell-NHD system in general three-dimensional configurations. Our estimator is of “residual” type, and builds upon previous constructions for standard Maxwell’s equations [4, 6, 19] with suitable modifications to handle the NHD model. Our second key contribution is a detailed mathematical analysis of the estimator, where we show that it is both reliable and efficient in a suitable energy norm. Finally, we numerically evaluate the ability of the estimator to drive adaptive processes, and quantify the computational savings as compared to uniform meshes. To this end, we consider three two-dimensional examples that are representative of typical nanoplasmonic applications. In each case, the use of adaptivity leads to a drastic reduction of the number of required degrees of freedom to achieve any given accuracy. These preliminary results are very promising in view of more realistic three-dimensional applications.

To the best of our knowledge, most existing studies on the NHD model focus on the development of numerical methods or the analysis of physical effects. In comparison, the rigorous mathematical analysis is relatively recent, and a priori error estimates have been only recently established [16]. As a result, the proposed analysis appears to be entirely original.
The remainder of this manuscript is organized as follows. In Section 2 we present our model problem, notations and preliminary results. Section 3 introduces the a posteriori error estimator and establishes our main theoretical results. We provide numerical examples in Section 4 and draw our conclusions in Section 5.

2. Settings

2.1. Maxwell-NHD equations. In this work, \( \Omega \subset \mathbb{R}^3 \) is a polyhedral Lipschitz domain, and \( \Omega_m \subset \subset \Omega \) is a Lipschitz polyhedral subset. \( \Omega_m \) can be multi-connected, but the boundaries of \( \Omega \) and \( \Omega_m \) are not allowed to touch each other. Whenever convenient, we will implicitly extend scalar-valued (resp. vector-valued) functions defined in \( \Omega_m \) by 0 (resp. \( \mathbf{0} \)) in \( \Omega \setminus \Omega_m \).

For the sake of simplicity, we consider a generalization of (1.2) with more general coefficients that we now describe. We assume that \( \Omega \) is subdivided into a polyhedral partition \( \mathcal{P} \) that is conforming with \( \Omega \) in the sense that any subset \( P \in \mathcal{P} \) either entirely belongs to \( \Omega \) or \( \Omega_m \). Then \( \varepsilon, \chi : \Omega \to \mathcal{L}(\mathbb{C}^3), \alpha : \Omega_m \to \mathcal{L}(\mathbb{C}^3) \) and \( \zeta : \Omega_m \to \mathbb{C} \) are assumed to be piecewise constant onto \( \mathcal{P} \).

We do not require the tensor-valued functions neither to be symmetric, nor to be positive-definite. Also, \( \zeta \) is allowed to change sign. The only assumption we require is that the problem is inf-sup stable (see Assumption 2.1 below) which implicitly constrains the coefficients.

For \( \mathbf{x} \in \Omega \), we denote by
\[
\varepsilon^*(\mathbf{x}) := \max_{\mathbf{u} \in \mathbb{C}^3} \max_{\|\mathbf{v}\| = 1} \text{Re} (\varepsilon(\mathbf{x}) \mathbf{u} \cdot \mathbf{v}), \quad \chi^*(\mathbf{x}) := \max_{\mathbf{u} \in \mathbb{C}^3} \max_{\|\mathbf{v}\| = 1} \text{Re} (\chi(\mathbf{x}) \mathbf{u} \cdot \mathbf{v})
\]
and similarly, for \( \mathbf{x} \in \Omega_m \), we write
\[
\alpha^*(\mathbf{x}) := \max_{\mathbf{u} \in \mathbb{C}^3} \max_{\|\mathbf{v}\| = 1} \text{Re} (\alpha(\mathbf{x}) \mathbf{u} \cdot \mathbf{v}), \quad \zeta^*(\mathbf{x}) := |\zeta(\mathbf{x})|.
\]

For the sake of simplicity, we implicitly extend \( \alpha^* \) and \( \zeta^* \) by zero in \( \Omega \setminus \Omega_m \). If \( \phi \in \{\varepsilon, \chi, \alpha, \zeta\} \), we introduce the notations \( \phi^*_K := \phi^*|_K \in \mathbb{R} \) as well as
\[
\phi_{D,\text{min}} := \text{ess inf}_{\mathbf{x} \in D} \phi^*(\mathbf{x}), \quad \phi_{D,\text{max}} := \text{ess sup}_{\mathbf{x} \in D} \phi^*(\mathbf{x})
\]
for any open set \( D \subset \Omega \), and we assume that \( \varepsilon_{\Omega,\text{min}}, \mu_{\Omega,\text{min}}, \alpha_{\Omega_m,\text{min}}, \zeta_{\Omega_m,\text{min}} > 0 \).

We are now ready to state our model problem. Namely, given \( J_e : \Omega \to \mathbb{C}^3 \) and \( K_e : \Omega_m \to \mathbb{C}^3 \), we seek \( \mathbf{E} : \Omega \to \mathbb{C}^3 \) and \( \mathbf{J} : \Omega_m \to \mathbb{C}^3 \) such that
\[
\begin{align*}
-\omega^2 \varepsilon \mathbf{E} + \nabla \times (\chi \nabla \times \mathbf{E}) + i\omega \mathbf{J} &= i\omega J_e \quad \text{in } \Omega, \\
-\omega^2 \alpha \mathbf{J} - \nabla \cdot (\zeta \nabla \cdot \mathbf{J}) - i\omega \mathbf{E} &= i\omega K_e \quad \text{in } \Omega_m.
\end{align*}
\]

On the one hand, we recover (1.2) when
\[
\varepsilon := \varepsilon_0 I, \quad \chi := \mu_0^{-1} I, \quad \alpha := \frac{1}{\omega^2 \varepsilon_0} \left( 1 - \frac{1}{i\omega} \gamma \right) I, \quad \zeta := \frac{\beta^2}{\omega^2 \varepsilon_0}.
\]

On the other hand, the proposed reformulation permits to treat more general cases in a uniform manner, without adding any mathematical complexity. In particular, the permittivity is allowed to change sign, which enables to take into account the local Drude model. Besides, our analysis naturally handles anisotropic materials, and in particular, perfectly matched layers can be employed to model unbounded propagation media [18].
For later use, we notice that as usual in the analysis of Maxwell’s equations, there are two “hidden” equations in (2.1), namely
\[ \nabla \cdot (\imath \omega \mathbf{E} + \mathbf{J}) = \nabla \cdot \mathbf{J}_e \quad \text{in } \Omega \]
and
\[ \nabla \times (\imath \omega \mathbf{a} \mathbf{J} - \mathbf{E}) = \nabla \times \mathbf{K}_e \quad \text{in } \Omega_m. \]

We also notice that there are three different (space-dependent) wavenumbers appearing in the above model. As usual, the electromagnetic wavenumber is defined in \( \Omega \) by
\[ k \equiv \frac{\omega}{c_E} = \sqrt{\frac{\varepsilon}{\varepsilon^*}}, \]
and in addition, we introduce
\[ k_J \equiv \frac{\omega}{c_J}, \quad k_P \equiv \frac{\omega}{c_P}, \quad c_J \equiv \sqrt{\frac{\varepsilon^*}{\alpha^*}}, \quad c_P \equiv \omega \sqrt{\varepsilon^*}. \]
in \( \Omega_m \). We add, for all the notations in (2.4), a second subscript \( K \) for the (constant) restrictions to \( K \in \mathcal{T}_h \).

2.2. Functional spaces. If \( D \subset \Omega \) is an open set, \( L^2(D) \) denotes the space of complex-valued square-integrable functions defined on \( D \), and \( L^2(D) := (L^2(D))^3 \). The notations \( \| \cdot \|_D \) and \( (\cdot, \cdot)_D \) stand for the usual norm and inner-product of \( L^2(D) \) and \( L^2(D) \). For \( \phi \in \{ \varepsilon, \chi, \alpha, \zeta \} \), we introduce the (equivalent) norms on \( L^2(D) \) and \( L^2(D) \) defined by
\[ \| w \|_{\phi, D}^2 := \int_D \phi |w|^2, \quad \| w \|_{j, D}^2 := \int_D \phi^* |w|^2, \]

\( w \in L^2(D) \) and \( w \in L^2(D) \).

\( H^1(D) \) is the usual first-order Sobolev space of functions \( v \in L^2(D) \) such that \( \nabla v \in L^2(D) \). If \( \Gamma \subset \partial \Omega \) is a relatively open set, \( H^1_\Gamma(D) \) stands for the space of functions \( v \in H^1(D) \) such that \( v |_\Gamma = 0 \). For vector-valued functions, we also introduce \( H_1(D) := (H^1(D))^3 \) and \( H^1_\Gamma(D) := (H^1_\Gamma(D))^3 \).

We will also need the vector Sobolev spaces
\[ \mathbf{H} \left( \text{curl}, D \right) := \left\{ \mathbf{v} \in L^2(D) \mid \nabla \times \mathbf{v} \in L^2(D) \right\}, \]
\[ \mathbf{H} \left( \text{div}, D \right) := \left\{ \mathbf{v} \in L^2(D) \mid \nabla \cdot \mathbf{v} \in L^2(D) \right\}, \]
and there subspaces \( \mathbf{H}_0(\text{curl}, D) \) and \( \mathbf{H}_0(\text{div}, D) \) that are defined, as usual, as the closure of smooth compactly supported functions.

The aforementioned functional spaces are widely documented in the literature, and we refer the reader to [11, 12] for a precise description.

We finally introduce the “energy” space
\[ \mathbb{V} := \mathbf{H}_0(\text{curl}, \Omega) \times \mathbf{H}_0(\text{div}, \Omega_m), \]
that we equip with the norm
\[ \| (\mathbf{e}, \mathbf{j}) \|_{\mathbb{V}}^2 := \omega^2 \| \mathbf{e} \|_{\varepsilon, \Omega}^2 + \| \nabla \times \mathbf{e} \|_{\chi, \Omega}^2 + \omega^2 \| \mathbf{j} \|_{\alpha, \Omega_m}^2 + \| \nabla \cdot \mathbf{j} \|_{\zeta, \Omega_m}^2, \quad (\mathbf{e}, \mathbf{j}) \in \mathbb{V}. \]

If \( D \subset \Omega \) is an open set, we will also use the local version
\[ \| (\mathbf{e}, \mathbf{j}) \|_{D}^2 := \omega^2 \| \mathbf{e} \|_{\varepsilon, D}^2 + \| \nabla \times \mathbf{e} \|_{\chi, D}^2 + \omega^2 \| \mathbf{j} \|_{\alpha, \Omega_m, D}^2 + \| \nabla \cdot \mathbf{j} \|_{\zeta, \Omega_m, D}^2, \quad (\mathbf{e}, \mathbf{j}) \in \mathbb{V}. \]
2.3. **Well-posedness.** We denote by $b: \mathbb{V} \times \mathbb{V} \to \mathbb{C}$ the sesquilinear form naturally associated with (2.1) after integration by parts. It is defined by

$$b((\mathbf{e}, j), (\mathbf{v}, w)) := - \omega^2(\mathbf{e} \mathbf{v})_{\Omega} + (\nabla \times \mathbf{e}, \nabla \times \mathbf{v})_{\Omega} + i\omega(j, v)_{\Omega_m}$$

for all $(\mathbf{e}, j), (\mathbf{v}, w) \in \mathbb{V}$. Then, a weak formulation of (2.1) consists in finding $(\mathbf{E}, \mathbf{J}) \in \mathbb{V}$ such that

$$b((\mathbf{E}, J), (\mathbf{v}, w)) = i\omega(\mathbf{J}, \mathbf{v}) + i\omega(\mathbf{K}, w) \quad \forall (\mathbf{v}, w) \in \mathbb{V}.$$}

In the remaining of this work, we require that the sesquilinear form $b$ is inf-sup stable, which implies well-posedness of (2.5). Specifically, we make the following assumption.

**Assumption 2.1 (Well-posedness).** There exists a constant $\mathcal{C}_{i/h}$ such that

$$\inf_{(\mathbf{e}, j) \in \mathbb{V} \setminus \{0\}} \sup_{(\mathbf{v}, w) \in \mathbb{V} \setminus \{0\}} \frac{\text{Re} b((\mathbf{e}, j), (\mathbf{v}, w))}{\|\mathbf{v}\| \|\mathbf{w}\|} \geq \mathcal{C}_{i/h} > 0.$$}

2.4. **Mesh.** We consider a mesh $\mathcal{T}_h$ of $\Omega$ made of tetrahedral elements $K$. $\mathcal{T}_h$ is conforming in the sense of [7], which means that the intersection $\overline{K_-} \cap \overline{K_+}$ of two distinct elements $K_\pm \in \mathcal{T}_h$ is either empty, or a single vertex, edge or face of both elements. We further assume that $\mathcal{T}_h$ is conforming with $\mathcal{P}$, in the sense for each $K \in \mathcal{T}_h$, there exists $P \in \mathcal{P}$ such that $\overline{K} \subset \overline{P}$. We denote by $\mathcal{T}_{m,h}$ the restriction of $\mathcal{T}_h$ to $\Omega_m$, i.e., the set of those $K \in \mathcal{T}_h$ such that $\overline{K} \subset \overline{\Omega}_m$.

Following [7], we employ the notations

$$h_K := \max_{x, y \in \overline{K}} |x - y|, \quad \rho_K := \max \{ r > 0 \mid \exists x \in \overline{K}; B(x, r) \subset \overline{K} \}$$

for the diameter and inscribed sphere radius of the element $K \in \mathcal{T}_h$. $\kappa_K := h_K/\rho_K$ is then called the shape-regularity parameter of $K$, and $\kappa := \max_{K \in \mathcal{T}_h} \kappa_K$ is the shape-regularity parameter of $\mathcal{T}_h$.

We introduce, for $K \in \mathcal{T}_h$ and $F \in \mathcal{F}_h$, the sets

$$\mathcal{T}_{K,h} := \{ K' \in \mathcal{T}_h \mid \overline{K} \cap \overline{K'} \neq \emptyset \}, \quad \mathcal{T}_{F,h} := \{ K' \in \mathcal{T}_h \mid F \subset \partial K' \},$$

and the associated open domains

$$\tilde{K} := \text{Int} \left( \bigcup_{K' \in \mathcal{T}_{K,h}} \overline{K'} \right), \quad \tilde{F} := \text{Int} \left( \bigcup_{K' \in \mathcal{T}_{F,h}} \overline{K'} \right).$$

When $K \in \mathcal{T}_{m,h}$ and $F \in \mathcal{F}_{m,h}$, we will also use the submeshes $\mathcal{T}_{m,K,h} := \mathcal{T}_{K,h} \cap \mathcal{T}_{m,h}$ and $\mathcal{T}_{m,F,h} := \mathcal{T}_{F,h} \cap \mathcal{T}_{m,h}$, and the associated open domains $\tilde{K}_m$ and $\tilde{F}_m$.

For $\mathcal{T} \subset \mathcal{T}_h$ and $\mathcal{F} \subset \mathcal{F}_h$, we write

$$\langle \cdot, \cdot \rangle_\mathcal{T} := \sum_{K \in \mathcal{T}} \langle \cdot, \cdot \rangle_K, \quad \langle \cdot, \cdot \rangle_{\partial \mathcal{T}} := \sum_{K \in \mathcal{T}} \langle \cdot, \cdot \rangle_{\partial K}, \quad \langle \cdot, \cdot \rangle_{\mathcal{F}} := \sum_{F \in \mathcal{F}} \langle \cdot, \cdot \rangle_{\mathcal{F}}$$

and

$$H^1(\mathcal{T}) := \{ v \in L^2(U) \mid v|_K \in H^1(K) \quad \forall K \in \mathcal{T} \},$$

with $U := \text{Int}(\cup_{K \in \mathcal{T}} \overline{K})$. 

2.5. Finite element spaces. The usual Lagrange and Nédélec spaces on $\mathcal{T}_h$ read

$$V_h := \mathcal{P}_{p+1}(\mathcal{T}_h) \cap H^1_0(\Omega), \quad W_h := \mathcal{N}_p(\mathcal{T}_h) \cap H^1_0(\text{curl}, \Omega),$$

and we have $\nabla V_h \subset W_h$. We shall also need the Nédélec and Raviart-Thomas finite element spaces in the metallic part of the domain, namely

$$W_{m,h} := \mathcal{N}_p(\mathcal{T}_{m,h}) \cap H^1_0(\text{curl}, \Omega_m), \quad X_{m,h} := \mathcal{RT}_p(\mathcal{T}_{m,h}) \cap H^1_0(\text{div}, \Omega_m).$$

We have $\nabla \times W_{m,h} \subset W_{h}$. In addition, if extension by zero is implicitly assumed, then $W_{m,h} \subset W_{h}$. We refer the reader to [26] for a detailed presentation and only state the essential finite element spaces.

2.6. Quasi-interpolation operators. Classically, our analysis will rely on “quasi-interpolation" operators [11]. Specifically, there exist four operators $\mathcal{P}_h : H^1_0(\Omega) \to V_h$, $\mathcal{Q}_h : H^1_0(\text{curl}, \Omega) \to W_h$, $\mathcal{Q}_{m,h} : H^1_0(\text{curl}, \Omega_m) \to W_{m,h}$ and $\mathcal{R}_{m,h} : H^1_0(\text{div}, \Omega_m) \to X_{m,h}$ and a constant $C_{qi}$ that only depends on the shape-regularity parameter $\kappa$ such that

\begin{align}
(2.7a) \quad & h_{m}^{-1} || p - \mathcal{P}_h q ||_K + h_{m}^{-1/2} || q - \mathcal{Q}_h q ||_{\partial K} \leq C_{qi} || \nabla q ||_{\bar{K}}, \\
(2.7b) \quad & h_{K}^{-1} || v - \mathcal{Q}_h v ||_K + h_{K}^{-1/2} || (v - \mathcal{Q}_h v) \times n ||_{\partial K} \leq C_{qi} || \nabla_h v ||_{\bar{K}}, \\
(2.7c) \quad & h_{K}^{-1} || w - \mathcal{Q}_{m,h} w ||_K + h_{K}^{-1/2} || (w - \mathcal{Q}_{m,h} w) \cdot n ||_{\partial K} \leq C_{qi} || \nabla_h w ||_{\bar{K}_m}, \\
(2.7d) \quad & h_{K}^{-1} || v - \mathcal{R}_{m,h} v ||_K + h_{K}^{-1/2} || (v - \mathcal{R}_{m,h} v) \cdot n ||_{\partial K} \leq C_{qi} || \nabla_h v ||_{\bar{K}_m},
\end{align}

for all $q \in H^1_0(\Omega)$, $v \in H^1(\mathcal{T}_h) \cap H^1_0(\text{curl}, \Omega)$ and $K \in \mathcal{T}_h$, as well as

\begin{align}
(2.7c) \quad & h_{K}^{-1} || w - \mathcal{Q}_{m,h} w ||_K + h_{K}^{-1/2} || (w - \mathcal{Q}_{m,h} w) \cdot n ||_{\partial K} \leq C_{qi} || \nabla_h w ||_{\bar{K}_m}, \\
(2.7d) \quad & h_{K}^{-1} || w - \mathcal{R}_{m,h} w ||_K + h_{K}^{-1/2} || (w - \mathcal{R}_{m,h} w) \cdot n ||_{\partial K} \leq C_{qi} || \nabla_h w ||_{\bar{K}_m},
\end{align}

for all $v \in H^1(\mathcal{T}_{m,h}) \cap H^1_0(\text{curl}, \Omega_m)$, $w \in H^1(\mathcal{T}_{m,h}) \cap H^1_0(\text{div}, \Omega_m)$, and $K \in \mathcal{T}_{m,h}$.

2.7. Bubble functions. Classically, we will use “bubble" functions to localize our error analysis. We refer the reader to [20] for a detailed presentation and only state the essential result we need. Given an element $K \in \mathcal{T}_h$ and a face $F \in \mathcal{F}_h$, we denote by $b_K \in H^1_0(K)$ and $b_F \in H^1_0(\bar{F})$ the element and face bubble functions supported in $K$ and $\bar{F}$, respectively. The estimates

\begin{align}
(2.8a) \quad & || w ||_K \leq C_b || h_{K}^{1/2} w ||_K, \quad || v ||_F \leq C_b || h_{F}^{1/2} v ||_F \\
(2.8b) \quad & || \nabla (w b_K) ||_K \leq C_i h_{K}^{-1} || w ||_K \quad \forall w \in \mathcal{P}_{p+1}(K), \\
(2.8c) \quad & || \mathcal{L}_F(v) ||_F + h_F || \nabla (\mathcal{L}_F(v)) ||_F \leq C_e h_{F}^{1/2} || v ||_F, \quad v \in \mathcal{P}_{p+1}(F),
\end{align}

hold for all $w \in \mathcal{P}_{p+1}(K)$ and $v \in \mathcal{P}_{p+1}(F)$, where $C_b > 0$ is a constant depending on the polynomial degree $p$ and the shape regularity parameter $\kappa$. Standard inverse inequalities let us conclude that

\begin{align}
(2.8b) \quad & || \nabla (w b_K) ||_K \leq C_i h_{K}^{-1} || w ||_K \quad \forall w \in \mathcal{P}_{p+1}(K), \\
(2.8c) \quad & || \mathcal{L}_F(v) ||_F + h_F || \nabla (\mathcal{L}_F(v)) ||_F \leq C_e h_{F}^{1/2} || v ||_F, \quad v \in \mathcal{P}_{p+1}(F),
\end{align}

where $C_i$ only depends on $\kappa$ and $p$. We further consider an extension operator $\mathcal{L}_F : \mathcal{P}_{p+1}(F) \to \mathcal{P}_{p+1}(\bar{F})$ such that $\mathcal{L}_F(v) |_F = v$ and

\begin{align}
(2.8c) \quad & || \mathcal{L}_F(v) ||_F + h_F || \nabla (\mathcal{L}_F(v)) ||_F \leq C_e h_{F}^{1/2} || v ||_F, \quad v \in \mathcal{P}_{p+1}(F),
\end{align}

where $C_e$ depends on $\beta$ and $p$. The same results hold true for vector-valued function, as can be seen by applying the scalar estimator componentwise.
2.8. Data oscillation. Our efficiency estimates include a data-oscillation term that we define in this section. We first define a “projected source term” \( \pi_h J_e \in P_{p+1}(T_h) \), that is defined for each \( K \in T_h \) as the unique element in \( P_{p+1}(K) \) such that
\[
\frac{\omega^2 h^2}{c_E K} (\pi_h J_e, v_h)_K + h^2 K (\nabla \cdot (\pi_h J_e), \nabla \cdot v_h)_K = \frac{\omega^2 h^2}{c_E K} (J_e, v_h)_K + h^2 K (\nabla \cdot J_e, \nabla \cdot v_h)_K
\]
for all \( v_h \in P_{k+1}(K) \). Analogously, we define \( \varrho_h K_e \in P_{p+1}(T_h) \), for each \( K \in T_h \), as the unique element in \( P_{p+1}(K) \) such that
\[
\frac{\omega^2 h^2}{c_J K} (\varrho_h K_e, w_h)_K + h^2 K (\nabla \times (\varrho_h K_e), \nabla \times w_h)_K = \frac{\omega^2 h^2}{c_J K} (K_e, w_h)_K + h^2 K (\nabla \times K_e, \nabla \times w_h)_K
\]
for all \( w_h \in P_{k+1}(K) \). Then, we may introduce the data oscillation term
\[
\text{osc}_K^2 := \frac{1}{\varepsilon_K} \left( \frac{\omega^2 h^2}{c_E K} \| J_e - \pi_h J_e \|^2_K + h^2 K \| \nabla \cdot (J_e - \pi_h J_e) \|^2_K \right) + \frac{1}{\alpha_K} \left( \frac{\omega^2 h^2}{c_J K} \| K_e - \varrho_h K_e \|^2_K + h^2 K \| \nabla \times (K_e - \varrho_h K_e) \|^2_K \right)
\]
for all \( K \in T_h \), and
\[
\text{osc}_K^2 := \sum_{K \in T_h^K} \text{osc}_K^2.
\]

Notice that whenever the right-hand side is smooth, namely \( J_e \in H^{p+1}(T_h) \), \( \nabla \cdot J_e \in H^{p+1}(T_h) \), \( K_e \in H^{p+1}(T_h) \) and \( \nabla \times K_e \in H^{p+1}(T_h) \), we have \( \text{osc}_K = O(h^{p+2}) \) for all \( K \in T_h \).

2.9. Regular decomposition. For all \( (v, w) \in V \), there exist \( q \in H^1(\Omega) \), \( \theta \in H^1(T_m,h) \cap H_0(\text{curl}, \Omega_m) \), \( \tilde{\nu} \in H^1(T_h) \cap H_0(\text{curl}, \Omega) \) and \( \tilde{w} \in H^1(T_m,h) \cap H_0(\text{div}, \Omega_m) \) such that
(2.9a) \[
(v, w) = (\nabla p + \tilde{v}, \nabla \theta + \tilde{w})
\]
and
(2.9b) \[
\omega \| \nabla q \|_{L^2(\Omega)} + \| \nabla \theta \|_{L^2(\Omega_m)} + \| \nabla \tilde{v} \|_{L^2(\Omega)} + \| \nabla \tilde{w} \|_{L^2(\Omega_m)} \leq C_{rd} \left\| (v, w) \right\|
\]
where \( C_{rd} \) is a constant that only depends on \( \mathcal{P} \), the ratio between the minimum and maximum value of the coefficients. We refer the reader to Theorems 2 and 6 of [13], as well as [6], Appendix B.

2.10. Inequalities with hidden constants. To simplify the remaining of the exposition, if \( A,B \geq 0 \) are real numbers, we employ the notation \( A \lesssim B \) if there exists a constant \( C \) that only depends on \( C_{\ell_1}, C_{\ell_2}, C_{\ell_3}, C_{\ell_4}, C_{\ell_5}, \kappa \) and the material contrasts such that \( A \leq CB \). In particular, \( C \) may depend on the geometry of the domain and the material coefficients, the mesh shape-regularity \( \kappa \) and the polynomial degree \( p \), but not on the mesh size \( h \).

3. A posteriori error estimates

3.1. Numerical solution. We are interested in finite element approximations to (2.5). Specifically, we introduce the (conforming) discretization space \( V_h := W_h \times X_m,h \) and consider an element \( (E_h, J_h) \in V_h \) such that
(3.1) \[
b((E_h, J_h), (v_h, w_h)) = i\omega (J_e, v_h) + i\omega (K_e, w_h) \quad \forall (v_h, w_h) \in V_h.
\]
3.2. **A posteriori error estimator.** We devise a residual-based error estimator. It is based on four terms. The first two are motivated by the two equations of (2.1) and read

\[
\eta_{\text{curl,curl},K} := \frac{h_K}{\sqrt{\chi_{K}^{\star}}} \left\| \omega^2 \varepsilon E_h + \nabla \times (\chi \nabla \times E_h) + i\omega J_h - i\omega J_e \right\|_K
\]

\[
+ \frac{h_K^{1/2}}{\sqrt{\chi_{K}^{\star}}} \left\| \nabla \times E_h \right\|_K \times n\|_{\partial K \setminus \partial \Omega}
\]

for all \( K \in \mathcal{T}_h \) and

\[
\eta_{\text{grad,div},K} := \frac{h_K}{\sqrt{\varepsilon_K}} \left\| \omega^2 \alpha J_h - \nabla (\zeta \nabla \cdot J_h) - i\omega E_h - i\omega K_e \right\|_K
\]

\[
+ \frac{h_K^{1/2}}{\sqrt{\varepsilon_K}} \left\| \nabla \cdot J_h \right\|_{\partial K \setminus \partial \Omega_m}
\]

for \( K \in \mathcal{T}_{m,h} \). As usual in the context of Maxwell’s equations [4, 19], these two terms are insufficient, and we also need to consider the residual terms associated with “hidden” equations (2.2) and (2.3). Hence, we introduce

\[
\eta_{\text{div},K} := \frac{h_K}{\sqrt{\varepsilon_K}} \left\| \nabla \cdot (i\omega \varepsilon E_h + J_h - J_e) \right\|_K + \frac{\omega h_K^{1/2}}{\sqrt{\varepsilon_K}} \left\| [\varepsilon E_h] \cdot n \right\|_{\partial K \setminus \partial \Omega}
\]

if \( K \in \mathcal{T}_h \) and

\[
\eta_{\text{curl},K} := \frac{h_K}{\sqrt{\alpha_K}} \left\| \nabla \times (i\omega \alpha J_h - E_h - K_e) \right\|_K + \frac{\omega h_K^{1/2}}{\sqrt{\alpha_K}} \left\| [\alpha J_h] \times n \right\|_{\partial K \setminus \partial \Omega_m}
\]

for all \( K \in \mathcal{T}_{m,h} \). We then set

\[
\eta_K := \eta_{\text{curl,curl},K} + \eta_{\text{grad,div},K} + \eta_{\text{div},K} + \eta_{\text{curl},K},
\]

for all \( K \in \mathcal{T}_h \) with the implicit convention that \( \eta_{\text{grad,div},K} = \eta_{\text{curl},K} = 0 \) when \( K \notin \mathcal{T}_{m,h} \). Finally,

\[
\eta := \left( \sum_{K \in \mathcal{T}_h} \eta_K^2 \right)^{1/2}
\]

gathers the elementwise contributions, and we define \( \eta_{\text{curl,curl}}, \eta_{\text{grad,div}}, \eta_{\text{div}} \) and \( \eta_{\text{curl}} \) in a similar way.

3.3. **Reliability.** We first establish that the proposed estimator is reliable. The key ingredient of the proof is to estimate, for an arbitrary element \((v, w) \in \mathcal{V}\), the quantity

\[
|b((E - E_h, J - J_h), (v, w))|
\]

using the estimator \( \eta \). This is done in four major steps, that are presented in Lemmas 3.1, 3.2, 3.3 and 3.4 below.

**Lemma 3.1.** We have

\[
|b((E - E_h, J - J_h), (\nabla q, o))| \lesssim \eta_{\text{div}} \omega \|\nabla q\|_{\mathcal{E},\Omega}
\]

for all \( q \in H_0^1(\Omega) \).
Upon rearranging the face sum, it follows that

\[ b((E - E_h, J - J_h), (\nabla p, o)) = -\omega^2 (\varepsilon (E - E_h), \nabla p)_{\mathcal{T}_h} + i\omega (J - J_h, \nabla p)_{\mathcal{T}_h} \]

\[ = i\omega ((i\omega \varepsilon E + J, \nabla p)_{\mathcal{T}_h} - (i\omega E_h - J_h, \nabla p)_{\mathcal{T}_h}). \]

Then, since \( \varepsilon, E, J_h \in H_0(\text{div}, \Omega) \) and \( p \in H_0^1(\Omega) \), elementwise integration by parts reveals that

\[ b((E - E_h, J - J_h), (\nabla p, o)) = i\omega (- (\nabla \cdot (i\omega \varepsilon E + J), p)_{\mathcal{T}_h} + (\nabla \cdot (i\omega \varepsilon E_h + J_h), p)_{\mathcal{T}_h}) \]

\[ - \omega^2 (\varepsilon E_h \cdot n, p)_{\partial \mathcal{T}_h} = i\omega (\nabla \cdot (i\omega \varepsilon E_h + J_h - J), p)_{\mathcal{T}_h} - \omega^2 \langle [\varepsilon E_h] \cdot n, p \rangle_{\mathcal{F}_h}. \]

Upon rearranging the face sum, it follows that

\[ |b((E - E_h, J - J_h), (\nabla p, o))| \lesssim \sum_{K \in \mathcal{T}_h} \eta_{\text{div}, K} \sqrt{\varepsilon E_h} \left( h_K^{-1} \| p \|_K + h_K^{-1/2} \| p \|_{\partial K} \right). \]

Now, let \( q \in H_0^1(\Omega) \). Using Galerkin orthogonality (3.1), the inclusion \( \nabla V_h \subset W_h \), and quasi-interpolation estimate (2.7a), we have

\[ |b((E - E_h, J - J_h), (\nabla q, o))| = |b((E - E_h, J - J_h), (\nabla (q - \mathcal{P}_h q), o))| \]

\[ \lesssim \sum_{K \in \mathcal{T}_h} \eta_{\text{div}, K} \sqrt{\varepsilon E_h} \left( h_K^{-1} \| q - \mathcal{P}_h q \|_K + h_K^{-1/2} \| q - \mathcal{P}_h q \|_{\partial K} \right) \]

\[ \lesssim \sum_{K \in \mathcal{T}_h} \eta_{\text{div}, K} \sqrt{\varepsilon E_h} \| \nabla q \|_{e, \Omega}, \]

and the result follows.

**Lemma 3.2.** We have

\[ |b((E - E_h, J - J_h), (o, \nabla \times \theta))| \lesssim \eta_{\text{curl}} \omega \| \nabla_h \theta \|_{e, \Omega_m} \]

for all \( \theta \in H^1(\mathcal{T}_{m,h}) \cap H_0(\text{curl}, \Omega_m) \).

**Proof.** Let \( \phi \in H^1(\mathcal{T}_{m,h}) \cap H_0(\text{curl}, \Omega_m) \). The first step of the proof consists in writing that

\[ b((E - E_h, J - J_h), (o, \nabla \times \phi)) = -\omega^2 (\alpha (J - J_h), \nabla \times \phi)_{\Omega_m} - i\omega (E - E_h, \nabla \times \phi)_{\Omega_m} \]

\[ = i\omega ((i\omega \alpha_j - E_h, \nabla \times \phi)_{\Omega_m} - (i\omega \alpha J_h - E_h, \nabla \times \phi)_{\Omega_m}). \]

Recalling (2.3), integrating by parts over each \( K \in \mathcal{T}_{m,h} \) reveals that

\[ b((E - E_h, J - J_h), (o, \nabla \times \phi)) = i\omega ((\nabla \times (i\omega \alpha_j - E), \phi)_{\mathcal{T}_{m,h}} - (\nabla \times (i\omega \alpha J_h - E_h), \phi)_{\mathcal{T}_{m,h}}) \]

\[ + \omega^2 (\alpha_j \times n, \phi)_{\partial \mathcal{T}_{m,h}} \]

\[ = -i\omega (\nabla \times (i\omega \alpha J_h - E_h - K), \phi)_{\mathcal{T}_{m,h}} + \omega^2 (\alpha J_h \times n, \phi)_{\partial \mathcal{T}_{m,h}} \]

\[ = -i\omega (\nabla_h \times (i\omega \alpha J_h - E_h - K), \phi)_{\Omega_m} + \omega^2 ([\alpha J_h] \times n, \phi)_{\mathcal{F}_{m,h}}, \]

and

\[ |b((E - E_h, J - J_h), (o, \nabla \times \phi))| \lesssim \sum_{K \in \mathcal{T}_{m,h}} \eta_{\text{curl}, K} \sqrt{\alpha K} \left( h_K^{-1} \| \phi \|_K + h_K^{-1/2} \| \phi \|_{\partial K} \right). \]
Let $\theta \in H^1(\mathcal{T}_{m,h}) \cap H_0(\text{curl}, \Omega_m)$. Then, recalling Galerkin orthogonality \cite{3.1}, that $\nabla \times W_{m,h} \subset X_{m,h}$ and \cite{2.7c}, we have
\[
|b((E - E_h, J - J_h), (o, \nabla \times \theta))| = |b((E - E_h, J - J_h), (o, \nabla \times (\theta - Q_{m,h}\theta)))|
\leq \sum_{K \in \mathcal{T}_{m,h}} \eta_{\text{curl}, K} \omega \sqrt{\alpha_K} \left( h_K^{-1}\|\theta - Q_{m,h}\theta\|_K + h_K^{-1/2}\|\theta - Q_{m,h}\theta \times n\|_{\partial K} \right)
\leq \sum_{K \in \mathcal{T}_{m,h}} \eta_{\text{curl}, K} \omega \sqrt{\alpha_K} \|\theta\|_{T^K_{m,h}} \leq \eta_{\text{curl}, \omega} \|\nabla \theta\|_{\partial K, \mathcal{T}_{m,h}}.
\]
\[
|b((E - E_h, J - J_h), (\tilde{v}, o))| \leq \eta_{\text{curl}, \text{curl}} \|\nabla h\|_{\tilde{v}} \|\nabla \tilde{v}\|_{\Omega, \mathcal{T}_{m,h}}.
\]

\[\square\]

**Lemma 3.3.** We have
\[
|b((E - E_h, J - J_h), (\tilde{v}, o))| \leq \eta_{\text{curl}, \text{curl}} \|\nabla h\|_{\tilde{v}} \|\nabla \tilde{v}\|_{\Omega, \mathcal{T}_{m,h}}
\]
for all $\tilde{v} \in H^1(\mathcal{T}_{h}) \cap H_0(\text{curl}, \Omega)$.

**Proof.** Let $\phi \in H^1(\mathcal{T}_{h}) \cap H_0(\text{curl}, \Omega)$. We have
\[
b((E - E_h, J - J_h), (\phi, o)) = -\omega^2(\varepsilon E_h, \phi)_{\mathcal{T}_h} + (\chi \nabla \times E_h, \nabla \times \phi)_{\mathcal{T}_h} = \omega^2 E_h + \nabla \times (\chi \nabla \times E_h) + \omega J_h \phi_{\mathcal{T}_h} + (\chi \nabla \times E_h) \times n, \phi)_{\mathcal{T}_h}.
\]
It follows that
\[
b((E - E_h, J - J_h), (\phi, o)) = \omega^2 E_h + \nabla \times (\chi \nabla \times E_h) + \omega J_h \phi_{\mathcal{T}_h} + (\chi \nabla \times E_h) \times n, \phi)_{\mathcal{T}_h},
\]
and
\[
|b((E - E_h, J - J_h), (\phi, o))| \leq \sum_{K \in \mathcal{T}_h} \eta_{\text{curl}, \text{curl}, K} \sqrt{\alpha_K} \left( h_K^{-1}\|\phi\|_K + h_K^{-1/2}\|\phi \times n\|_{\partial K} \right).
\]
Then, we consider $\tilde{v} \in H^1(\mathcal{T}_{h}) \cap H_0(\text{curl}, \Omega)$ and conclude the proof thanks to Galerkin orthogonality \cite{3.1} and estimate \cite{2.7b}, since
\[
|b((E - E_h, J - J_h), (\tilde{v}, o))| = |b((E - E_h, J - J_h), (\tilde{v} - Q_h\tilde{v}, o))|
\leq \sum_{K \in \mathcal{T}_h} \eta_{\text{curl}, \text{curl}, K} \sqrt{\alpha_K} \left( h_K^{-1}\|\tilde{v} - Q_h\tilde{v}\|_K + h_K^{-1/2}\|\tilde{v} - Q_h\tilde{v} \times n\|_{\partial K} \right)
\leq \sum_{K \in \mathcal{T}_h} \eta_{\text{curl}, \text{curl}, K} \sqrt{\alpha_K} \|\nabla h\|_{\tilde{v}} \|\nabla \tilde{v}\|_K \leq \eta_{\text{curl}, \text{curl}} \|\nabla h\|_{\tilde{v}} \|\nabla \tilde{v}\|_{\Omega, \mathcal{T}_{m,h}}.
\]
\[
\square\]

**Lemma 3.4.** We have
\[
|b((E - E_h, J - J_h), (\phi, o))| \leq \eta_{\text{curl}, \text{curl}} \|\nabla \phi\|_{\Omega, \mathcal{T}_{m,h}}
\]
for all $\tilde{w} \in H^1(\mathcal{T}_{m,h}) \cap H_0(\text{div}, \Omega_m)$. 
Theorem 3.5. We have

\[ b((E - E_h, J - J_h), (o, \phi)) = i\omega(K_e, \phi)_{m,h} + \omega^2(\alpha J_h, \phi)_{m,h} - (\zeta \cdot J_h, \nabla \cdot \phi)_{m,h} + i\omega(E_h, \phi)_{m,h} \]

\[ = -(-\omega^2 \alpha J_h - \nabla (\zeta \cdot J_h) - i\omega E_h - i\omega K_e, \phi)_{m,h} - (\zeta \cdot J_h, \phi \cdot n)_{\partial T_m,h} \]

and

\[ |b((E - E_h, J - J_h), (o, \phi))| \lesssim \sum_{K \in T_{m,h}} \eta_{\text{grad}, \text{div}, K} \sqrt{\zeta_K} \left( h^{-1}_K \|\phi\|_K + h^{-1/2}_K \|\phi\|_{\partial K} \right). \]

Now, let \( \tilde{w} \in H^1(T_{m,h}) \cap H_0(\text{div}, \Omega_m) \). By Galerkin orthogonality and the estimate (2.7d), we conclude

\[ |b((E - E_h, J - J_h), (o, \tilde{w}))| = |b((E - E_h, J - J_h), (o, \tilde{w} - R_{m,h} \tilde{w})| \lesssim \sum_{K \in T_{m,h}} \eta_{\text{grad}, \text{div}, K} \sqrt{\zeta_K} \left( h^{-1}_K \|\tilde{w} - R_{m,h} \tilde{w}\|_K + h^{-1/2}_K \|\tilde{w} - R_{m,h} \tilde{w}\|_{\partial K} \right) \]

\[ \lesssim \sum_{K \in T_{m,h}} \eta_{\text{grad}, \text{div}, K} \sqrt{\zeta_K} \|\nabla \tilde{w}\|_{\mathcal{T}_{m,h}} \lesssim \eta_{\text{grad}, \text{div}} \|\nabla \tilde{w}\|_{\zeta, T_{m,h}}. \]

We now establish that the proposed estimator is reliable in Theorem 3.5. The proof builds upon Lemmas 3.1, 3.2, 3.3 and 3.4 combined with inf-sup condition (2.6) and regular decomposition (2.9).

**Theorem 3.5.** We have

\[ \|(E - E_h, J - J_h)\| \lesssim \eta. \]

**Proof.** Since \( \mathbb{V} \) in a Hilbert space, it follows from inf-sup condition (2.6) that there exists \((v^*, w^*) \in \mathbb{V}\) with \(|(v^*, w^*)| = 1\) such that

\[ \|(E - E_h, J - J_h)\| \leq \sqrt{\eta^{-1}} \text{ Re } b((E - E_h, J - J_j), v^*, w^*). \]

Then, using (2.9), we have

\[ v^* = \tilde{v} + \nabla p, \quad w^* = \tilde{w} + \nabla \times \theta, \]

where \( \tilde{v} \in H^1(T_h) \cap H_0(\text{curl}, \Omega, p) \), \( p \in H^1_0(\Omega) \), \( \tilde{w} \in H^1(T_{m,h}) \cap H_0(\text{div}, \Omega_m) \) and \( \theta \in H^1(T_{m,h}) \cap H_0(\text{curl}, \Omega_m) \) with

\[ \omega \|\nabla q\|_{\text{div}, \Omega} + \omega \|\nabla h \theta\|_{\alpha, R_m} + \|\nabla_h \tilde{v}\|_{\text{curl}, \Omega} + \|\nabla_h \tilde{w}\|_{\text{curl}, \Omega_m} \lesssim \|(v^*, w^*)\| = 1, \]

and (3.2) follows by linearity and the estimates established in Lemma 3.1, 3.2, 3.3 and 3.4. \( \square \)

**3.4. Efficiency.** We show that the proposed estimator is efficient. To this end, we establish four results that provide upper bounds for each of the four terms constituting our estimator.

**Lemma 3.6.** The estimate

\[ \eta_{\text{div}, K} \lesssim (1 + k_{P,K} h_K) \|(E - E_h, J - J_h)\|_{K} + \text{ osc } K, \]

holds true for all \( K \in T_h \).
Proof. Using (2.4), we first record that the estimate
\begin{equation}
\frac{h_K}{\sqrt{\varepsilon_K}} \| \nabla \cdot (J - J_h) \|_K \lesssim k_{P,K} h_K \| (E - E_h, J - J_h) \|_K,
\end{equation}
holds true for any $K \in T_h$.

We then fix $K \in T_h$, and introduce the notations $r_K := i \omega \varepsilon E_h + J_h - J_e$ and $r_h^K := \pi_h r_K$.

Recalling (2.2), we have
\[- \nabla \cdot r_h^K = i \omega \nabla \cdot (\varepsilon (E - E_h)) + \nabla \cdot (J - J_h) - \nabla \cdot (J_e - \pi_h J_e),
\]
and thanks to (2.8a)
\begin{equation}
\| \nabla \cdot r_h^K \|_{0,K} \lesssim |(b_K \nabla \cdot r_h^K, \nabla \cdot r_h^K)|_K.
\end{equation}

Then, we use (2.8b) to estimate the two terms in the right-hand side of (3.5) with
\[|(b_K \nabla \cdot r_h^K, \nabla \varepsilon (E - E_h))| \leq h^{-1}_K \| \nabla \cdot r_h^K \|_K \| \varepsilon (E - E_h) \|_K
\]
and
\[|(b_K \nabla \cdot r_h^K, \nabla \cdot (J - J_h) + \nabla \cdot (J_e - \pi_h J_e))| \leq \| \nabla \cdot r_h^K \|_K \| \nabla \cdot (J - J_h) \|_K + \| \nabla \cdot (J_e - \pi_h J_e) \|_K.
\]

Then, after observing $r_h^K - r_K = J_e - \pi_h J_e$, we conclude that
\begin{equation}
\frac{h_K}{\sqrt{\varepsilon_K}} \| \nabla \cdot r_K \|_K \lesssim (1 + k_{P,K} h_K) \| (E - E_h, J - J_h) \|_K + \text{osc}_K.
\end{equation}

Now, if $F \in F_K$, we let $w_F := b_F \mathcal{L}_F(\varepsilon E_h \cdot n_F)$. Since $\varepsilon E \in H(\text{div}, \bar{F})$ and $w_F \in H^1_0(\bar{F})$,
we can employ integration by parts and (2.8a) to show that
\[\| \varepsilon E_h \cdot n_F \|_F \lesssim \| (\varepsilon E_h \cdot n_F, w_F) \|_F = \| (\varepsilon (E - E_h), \nabla w_F) \|_\bar{F} + \| \nabla \cdot (\varepsilon (E - E_h), w_F) \|_\bar{F},
\]
and it follows from (2.8c) that
\begin{equation}
\frac{\omega h^{1/2}_K}{\sqrt{\varepsilon_K}} \| \varepsilon E_h \cdot n_F \|_F \lesssim \omega \| E - E_h \|_{\varepsilon, \bar{F}} + \frac{\omega h_K}{\sqrt{\varepsilon_K}} \| \nabla \cdot (\varepsilon (E - E_h)) \|_\bar{F}.
\end{equation}

Recalling (2.2), we have
\[\nabla \cdot (i \omega \varepsilon (E - E_h)) = \nabla \cdot (i \omega \varepsilon E_h + J_h - J_e) + \nabla \cdot (J - J_h),
\]
and (2.4), (3.4) as well as (3.6) show that
\begin{equation}
\frac{\omega h_K}{\sqrt{\varepsilon_K}} \| \nabla \cdot (\varepsilon (E - E_h)) \|_\bar{F} \lesssim (1 + k_{P,K} h_K) \| (E - E_h, J - J_h) \|_\bar{F} + \text{osc}_K.
\end{equation}

Then, (3.3) follows from (3.6), (3.7) and (3.8). \hfill \Box
Lemma 3.7. The estimate

\[(3.9) \quad \eta_{\text{curl}, K} \lesssim \left(1 + \frac{c_{1,K}}{c_{E,K}} k_{P,K} h_{K}\right) \|(E - E_h, J - J_h)\|_{\mathcal{K}}\]

holds true for all $K \in \mathcal{T}_h$.

Proof. Thanks to (2.3), (2.8a) and after integrating by parts, we obtain that

\[(3.10) \quad \|\nabla \times (i\omega \alpha J_h - E_h - \varrho_h K_e)\|_{\mathcal{K}}^2 \\lesssim \|(b_K \nabla \times (i\omega \alpha J_h - E_h - \varrho_h K_e), \nabla \times (E - E_h))\|_{\mathcal{K}}\|
\]

for all $K \in \mathcal{T}_h$.

Now, for the terms in the right-hand side of (3.10), we use (2.8b) and have

\[\|(\nabla \times (b_K \nabla \times (i\omega \alpha J_h - E_h - \varrho_h K_e), i\omega \alpha (J - J_h))\|_{\mathcal{K}} \lesssim h_K^{-1} \|\nabla \times (i\omega \alpha J_h - E_h - \varrho_h K_e)\|_{\mathcal{K}} \|\alpha(J - J_h)\|_{\mathcal{K}}\]

and

\[\|(b_K \nabla \times (i\omega \alpha J_h - E_h - \varrho_h K_e), \nabla \times (E - E_h))\|_{\mathcal{K}} \\lesssim \|\nabla \times (i\omega \alpha J_h - E_h - \varrho_h K_e)\|_{\mathcal{K}} \|\nabla \times (E - E_h)\|_{\mathcal{K}}\]

Then,

\[\frac{h_K}{\sqrt{\alpha_K}} \|\nabla \times (i\omega \alpha J_h - E_h - \varrho_h K_e)\|_{\mathcal{K}} \lesssim \omega \|J - J_h\|_{\alpha,K} + \frac{h_K}{\sqrt{\lambda_K \alpha_K}} \|\nabla \times (E - E_h)\|_{\alpha,K} + \frac{h_K}{\sqrt{\lambda_K \alpha_K}} \|\nabla \times (K_e - \varrho_h K_e)\|_{\alpha,K}\]

and recalling (2.4), we conclude that

\[(3.11) \quad \frac{h_K}{\sqrt{\alpha_K}} \|\nabla \times (i\omega \alpha J_h - E_h - K_e)\|_{\mathcal{K}} \lesssim \left(1 + \frac{c_{1,K}}{c_{E,K}} k_{P,K} h_{K}\right) \|(E - E_h, J - J_h)\|_{\mathcal{K}} + \text{osc}_{\mathcal{K}}\]

On the other hand, for a fixed $K \in \mathcal{T}_h$, if $F \in \mathcal{F}_K$ we set $w_F := b_F, \mathcal{Z}(\alpha J_h) \times n_F)$. Recalling that $\alpha J \in H(\text{curl}, \bar{F})$ and $b_F \in H_0^1(\bar{F})$, and using (2.8a), we have

\[\|([\alpha J_h] \times n_F)\|_{\bar{F}} \lesssim \|([\alpha J_h] \times n_F, w_F)\|_{\bar{F}} = \|([\alpha (J - J_h), \nabla \times w_F)\|_{\bar{F}} + \|\nabla \times (\alpha(J - J_h)), w_F)\|_{\bar{F}}\]

and thanks to (2.8c), we get that

\[(3.12) \quad \frac{\omega h_K^{1/2}}{\sqrt{\alpha_K}} \|([\alpha J_h] \times n_F)\|_{\bar{F}} \lesssim \omega \|J - J_h\|_{\alpha,\bar{F}} + \frac{\omega h_K}{\sqrt{\alpha_K}} \|\nabla \times (\alpha(J - J_h))\|_{\bar{F}}\]

Invoking (2.3), we have

\[\nabla \times (i\omega \alpha(J - J_h)) = -\nabla \times (i\omega \alpha J_h - E_h - K_e) + \nabla \times (E - E_h)\]
and then, (2.4) and (3.11) let us conclude that
\[
\frac{\omega h_K}{\sqrt{\chi_K}} \left\| \nabla \times (\alpha(J - J_h)) \right\|_F \lesssim \left( 1 + \frac{c_{1,K}}{c_{E,K}} k_{P,K} h_K \right) \left\| (E - E_h, J - J_h) \right\|_F + \text{osc}_K.
\]
Finally, (3.9) follows from (3.11), (3.12) and (3.13). \hfill \square

**Lemma 3.8.** The estimate
\[
\eta_{\text{curl}, \text{curl}, K} \lesssim \left( 1 + \left( k_{E,K} + \frac{c_{1,K}}{c_{E,K}} k_{P,K} \right) h_K \right) \left\| (E - E_h, J - J_h) \right\|_K + \text{osc}_K
\]
holds true for all $K \in \mathcal{T}_h$.

**Proof.** For a fixed $K \in \mathcal{T}_h$, we set $r_K := -\omega^2 \varepsilon E_h + \nabla \times (\chi \nabla \times E_h) + i\omega J_h - i\omega J_e$ and $r^b_K := \pi_h r_K$. Then, considering (2.1), (2.8a) and integrating by parts, we get
\[
\left\| r^b_K \right\|_K^2 \lesssim \left| (r^h_K, b_K r^b_K) \right| \lesssim \left| (\omega^2 \varepsilon (E - E_h), b_K r^h_K) \right| + \left| (\chi \nabla \times (E - E_h), \nabla \times (b_K r^h_K)) \right| + \left| (i\omega (J - J_h), b_K r^h_K) \right|.
\]
To bound the right-hand side terms in (3.15), we use (2.8b) to obtain
\[
\left| (\omega^2 \varepsilon (E - E_h), b_K r^h_K) \right| \lesssim \omega^2 \| \varepsilon (E - E_h) \|_K \| r^h_K \|_K,
\]
\[
\left| \chi \nabla \times (E - E_h), \nabla \times (b_K r^b_K) \right| \lesssim h_K^{-1} \left\| \chi \nabla \times (E - E_h) \right\|_K \| r^h_K \|_K,
\]
\[
\left| (i\omega (J - J_h), b_K r^h_K) \right| \lesssim \omega \| J - J_h \|_K \| r^h_K \|_K,
\]
and we have that
\[
\frac{h_K}{\sqrt{\chi_K}} \left\| r^h_K \right\|_K \lesssim \frac{\omega h_K}{\sqrt{\chi_K}} \left\| (E - E_h) \right\|_K + \frac{1}{\sqrt{\chi_K}} \left\| \chi \nabla \times (E - E_h) \right\|_K + \frac{\omega h_K}{\sqrt{\chi_K}} \| J - J_h \| + \text{osc}_K.
\]
Noticing that $r^h_K - r_K = i\omega (J_e - \pi_h J_e)$ and recalling (2.4), we get
\[
\frac{h_K}{\sqrt{\chi_K}} \left\| r_K \right\|_K \lesssim \left( 1 + \left( k_{E,K} + \frac{c_{1,K}}{c_{E,K}} k_{P,K} \right) h_K \right) \left\| (E - E_h, J - J_h) \right\|_K + \text{osc}_K.
\]
Now, for $F \in \mathcal{F}_h$, we define $w_F := b_F \mathcal{L}_F (\varepsilon E_h) \cdot n_F$. Since $\chi \nabla \times E \in H(\text{curl}, \tilde{F})$ and $w_F \in H^1(\tilde{F})$, using (2.8a) and integrating by parts, we see that
\[
\| \chi \nabla \times E_h \|_F^2 \lesssim \| (\chi \nabla \times E_h, n_F, w_F)_F \| = \| (\nabla \times (\chi \nabla \times (E - E_h), w_F)_F - (\chi \nabla \times (E - E_h), \nabla \times w_F)_F.
\]
Thanks to (2.1), we deduce that
\[
\| \chi \nabla \times E_h \|_F^2 \lesssim \left| (\omega^2 \varepsilon (E - E_h), w_F) + (\nabla \times (E - E_h), \nabla \times w_F)_F \right|
\]

---

This page contains mathematical equations and proofs related to error estimates for non-local Maxwell-Drude equations. The document likely discusses the derivation of error bounds and the application of certain estimates to derive bounds on the error in numerical approximations of these equations. The equations and proofs are technical and require a good understanding of vector calculus, functional analysis, and numerical methods in partial differential equations.
and then, thanks to (2.8c), we have that
\[
\frac{h_{K}^{1/2}}{\sqrt{\hat{\chi}_K}} \| [\chi \nabla \times E_h] \times n_F \|_F \lesssim \frac{\omega^2 h_K}{\sqrt{\hat{\chi}_K}} \| (E - E_h) \|_F + \frac{1}{\sqrt{\hat{\chi}_K}} \| \chi \nabla \times (E - E_h) \|_F + \frac{\omega h_K}{\sqrt{\hat{\chi}_K}} \| J - J_h \|_F + \frac{h_K}{\sqrt{\hat{\chi}_K}} \| r_K \|_F.
\]

Finally, (2.4) shows that
\[
(3.17) \quad \frac{h_{K}^{1/2}}{\sqrt{\hat{\chi}_K}} \| [\chi \nabla \times E_h] \times n_F \|_F \lesssim \left(1 + \left(k_{E,K} + \frac{c_{1,K} K_{P,K}}{c_{E,K}} \right) h_K \right) \| (E - E_h, J - J_h) \|_F
\]
\[
+ \frac{h_K}{\sqrt{\hat{\chi}_K}} \| r_K \|_F
\]
and hence (3.14) is a direct consequence of (3.16) and (3.17).

\[\Box\]

Lemma 3.9. The estimate
\[
(3.18) \quad \eta_{\text{grad, div}, K} \lesssim (1 + (k_{E,K} + k_{1,K}) h_K) \| (E - E_h, J - J_h) \|_K + \text{osc}_K
\]
holds true for all $K \in \mathcal{T}_h$.

Proof. For a fixed $K \in \mathcal{T}_h$, let $r_K := -\omega^2 \alpha J_h - \nabla (\zeta \nabla \cdot J_h) - i \omega E_h - i \omega \theta_h K_e$ and $r_K^h := \theta_h r_K$. Then, after integrating by parts and thanks to (2.8a), we have that
\[
\| r_K^h \|_K^2 \lesssim |(r_K^h, b_K r_K^h)_K|
\]
\[
= |(\omega^2 \alpha (J - J_h), b_K r_K^h)_K + (\zeta \nabla \cdot (J - J_h), \nabla \cdot (b_K r_K^h))_K + (i \omega (E - E_h), b_K r_K^h)_K
\]
\[
+ (i \omega (K_e - \theta_h K_e), b_K r_K^h)_K|
\]
and thus, using (2.8b), we obtain
\[
\frac{h_K}{\sqrt{\hat{\chi}_K}} \| r_K^h \|_K \lesssim \frac{\omega^2 h_K}{\sqrt{\hat{\chi}_K}} \| \alpha (J - J_h) \|_K + \frac{h_K}{\sqrt{\hat{\chi}_K}} \| \zeta \nabla \cdot (J - J_h) \|_K + \frac{\omega h_K}{\sqrt{\hat{\chi}_K}} \| E - E_h \|_K + \text{osc}_K.
\]
Recalling (2.4), we get that
\[
(3.19) \quad \frac{h_K}{\sqrt{\hat{\chi}_K}} \| r_K \|_K \lesssim (1 + (k_{1,K} + k_{P,K}) h_K) \| (E - E_h, J - J_h) \|_K + \text{osc}_K.
\]

On the other hand, for $F \in \mathcal{F}_K$, we set $w_F := b_F L_F(\| \zeta \nabla \cdot J_h \| n_F)$. Thanks to the fact that $\zeta \nabla \cdot J \in H^1(\bar{F})$ and $b_F \in H^1(\bar{F})$, estimate (2.8a) and integration by parts reveal that
\[
\| \| \zeta \nabla \cdot J_h \|_F^2 \lesssim \| (\zeta \nabla \cdot J_h, w_F)_F \| = \| (\nabla (\zeta \nabla \cdot (J - J_h)), w_F)_F + (\zeta \nabla \cdot (J - J_h), \nabla \cdot w_F)_F \|.
\]

Using (2.1), we have that
\[
\| \| \zeta \nabla \cdot J_h \|_F^2 \lesssim
\]
\[
- (\omega^2 \alpha (J - J_h), w_F)_F + (\zeta \nabla \cdot (J - J_h), \nabla \cdot w_F)_F - (i \omega (E - E_h), w_F)_F + (r_K^h, w_F)_F.
\]
Theorem 3.10. The estimate (4.1) leading to (3.18) follows from (3.19) and (3.20).

Then, (2.4) let us conclude that

\[
\frac{h_K^{1/2}}{\sqrt{\zeta_K}} \| \xi \nabla \cdot J_h \|_F \lesssim \frac{\omega^2 h_K}{\sqrt{\zeta_K}} \| \alpha (J - J_h) \|_F + \frac{1}{\sqrt{\zeta_K}} \| \varsigma \nabla \cdot (J - J_h) \|_F + \frac{\omega h_K}{\sqrt{\zeta_K}} \| E - E_h \|_F + \frac{h_K}{\sqrt{\zeta_K}} \| r_K \|_F.
\]

Then, (3.20) follows from (3.19) and (3.20).

**Theorem 3.10.** The estimate

\[
(3.21) \quad \eta_K \lesssim \left( 1 + \left( k_{E,K} + k_{I,K} + \left( 1 + \frac{c_{l,K}}{c_{E,K}} \right) k_{P,K} \right) h_K \right) \|(E - E_h, J - J_h)\|_F + \frac{h_K}{\sqrt{\zeta_K}} \| r_K \|_F,
\]

holds true for all $K \in \mathcal{T}_h$. \hfill \Box

## 4. Numerical Examples

### 4.1. Settings

We first present the settings and methodology common to our three examples.

#### 4.1.1. Two-dimensional notations

Our numerical experiments are performed in a two-dimensional setting. We thus assume that the last component of the fields $E$, $J$, $J_e$ and $K_e$ vanishes and that the first two components only depend on the $(x_1, x_2)$ space variables. We further assume that the coefficients take the form

\[
\varepsilon = \begin{pmatrix} \varepsilon_{11} & \varepsilon_{12} & 0 \\ \varepsilon_{21} & \varepsilon_{22} & 0 \\ 0 & 0 & \varepsilon_{33} \end{pmatrix}, \quad \chi = \begin{pmatrix} \chi_{11} & \chi_{12} & 0 \\ \chi_{21} & \chi_{22} & 0 \\ 0 & 0 & \chi \end{pmatrix}, \quad \alpha = \begin{pmatrix} \alpha_{11} & \alpha_{12} & 0 \\ \alpha_{21} & \alpha_{22} & 0 \\ 0 & 0 & \alpha_{33} \end{pmatrix},
\]

leading to

\[
\begin{cases}
-\omega^2 \varepsilon E + \text{curl}(\chi \text{curl} E) + i\omega J = J_e & \text{in } \Omega, \\
-\omega^2 \alpha J - \nabla (\varsigma \nabla \cdot J) - i\omega E = K_e & \text{in } \Omega_m,
\end{cases}
\]

where the boldface notation now stands for two-components vectors and tensors. As usual, the two-dimensional curl operators are given by

\[
\text{curl } \phi = \partial_1 \phi_2 - \partial_2 \phi_1 \quad \text{curl } \phi = (\partial_2 \phi_1, -\partial_1 \phi).
\]

#### 4.1.2. Perfectly matched layers

We employ perfectly matched layers to incorporate the radiation condition into a bounded computational domain. In our examples, we assume for the sake of simplicity that $\varepsilon$ is diagonal and that the metallic particles are contained into a box $\Omega_0 := (-L, L)^2$ for some $L > 0$. We enclose $\Omega_0$ into a larger box $\Omega := (L - \ell, L + \ell)^2$ featuring an additional layer of size $\ell > 0$. Following [18], we define

\[
d_j(x) := 1 - \frac{3}{4} I_{|x| > \ell}
\]

for $j = 1$ or $2$, and construct modified coefficients

\[
\tilde{\varepsilon} := \begin{pmatrix} d_2/d_1 & 0 & 0 \\ 0 & d_1/d_2 \end{pmatrix} \varepsilon, \quad \tilde{\chi} := \frac{\chi}{d_1 d_2}.
\]
These new coefficients are actually unchanged in \( \Omega_0 \), but take artificial values in the additional layer designed to absorb incoming radiations without spurious reflections. In the remaining of this section, we employ the artificial coefficients \( \tilde{\varepsilon} \) and \( \tilde{\chi} \), but omit the \( \tilde{\cdot} \) notation to ease the presentation.

4.1.3. Incident field injection. We consider the scattering of an incident plane wave by metallic nanostructures. The total field \( E^t \) splits into the (known) incident field \( E^i \) and the scattered field \( E \) that we numerically approximate. We decompose the computational domain as \( \Omega = \Omega_m \cup \Omega_0 \cup \Omega_p \), where \( \Omega_m \) corresponds to the metallic inclusions, \( \Omega_p \) is the PML region, and \( \Omega_0 := \Omega \setminus (\Omega_m \cup \Omega_p) \). \( E^i \) is a solution to Maxwell’s equations in \( \Omega_0 \). \( E \) is a scattered field that satisfies the PML equation inside \( \Omega_p \). Finally, the total field \( E^t \) satisfies the Maxwell-Drude system in \( \Omega_0 \cup \Omega_m \). It follows that the pair \( (E, J) \) is solution to (4.1) with \( J_e := o \) and \( K_e := i\omega E^i \). In the forthcoming examples, we will only consider right-hand sides of this form, where

\[
E^i(x) = p e^{-i k d \cdot x},
\]

where \( p, d \) are two unit vectors such that \( p \cdot x \) and \( k := \omega/c_0 \). \( p \) and \( d \) respectively describe the polarization and the direction of the incident wave, while \( c_0 := \sqrt{\varepsilon_0 \mu_0} \) is the speed of light and \( k \), the wavenumber.

4.1.4. Coefficients. The permittivity and permeability are set to the vacuum values in \( \Omega_0 \), that is

\[
\varepsilon = I \varepsilon_0, \quad \chi = \frac{1}{\mu_0},
\]

with the aforementioned modification in the PML region \( \Omega_p \). In the metal, the coefficients \( \alpha \) and \( \zeta \) are defined from \( \omega_p, \gamma \) and \( \vartheta_f \) by

\[
\alpha := \frac{1}{\omega_p^2 \varepsilon_0} \left( 1 - \frac{\gamma}{i \omega} \right) I, \quad \zeta := \frac{3}{5} \frac{\varepsilon_F^2}{\omega_p^2 \varepsilon_0}.
\]

The actual values of \( \omega_p, \gamma \) and \( \vartheta_f \) depend on the particular metal under consideration. For gold, we have

\[
\omega_p := 1.390 \cdot 10^{16} \text{ rad} \cdot \text{s}^{-1}, \quad \gamma := 3.230 \cdot 10^{13} \text{ rad} \cdot \text{s}^{-1}, \quad \vartheta_F := 1.084 \cdot 10^6 \text{ m} \cdot \text{s}^{-1},
\]

while for silver, we employ

\[
\omega_p := 1.339 \cdot 10^{16} \text{ rad} \cdot \text{s}^{-1}, \quad \gamma := 1.143 \cdot 10^{14} \text{ rad} \cdot \text{s}^{-1}, \quad \vartheta_F := 1.465 \cdot 10^6 \text{ m} \cdot \text{s}^{-1}.
\]

4.1.5. Adaptive algorithm. In the following examples, we employ the estimator described before to steer an adaptive mesh algorithm process. We fix once and for all the polynomial degree \( p \) and start with an initial mesh \( \mathcal{T}_h^{(0)} \). Then, assuming we arrived at a mesh \( \mathcal{T}_h^{(\ell)} \), we solve the finite element system associated with this mesh, and compute the associated elementwise error estimators \( \eta_K \). These estimators are in turn used to output a new mesh \( \mathcal{T}_h^{(\ell+1)} \), enabling the start of new iteration. We employ the software packages MUMPS \cite{2005B02} to solve the linear systems, and MMG \cite{2000B02} to generate the meshes. Algorithm \cite{2000B02} describes the resulting procedure. Notice that MMG refines an existing mesh \( \mathcal{T} \) by following new local mesh sizes \( h_a \) that are given on the vertices \( a \) of \( \mathcal{T} \). As a result, Algorithm \cite{2000B02} includes a “translation” between the “element-based” estimator \( \eta_K \) and the data \( h_a \) passed to MMG.

The adaptive procedure takes two additional parameters \( \theta \) and \( \rho \) that controls how many elements are refined at each iteration, and how much their sizes is reduced. In the examples below, we always select \( \theta := 0.05 \) and \( \rho := 0.5 \). While we mean that we refine elements
Algorithm 1 Adaptive loop

1: procedure GENERATE_MESH($\mathcal{T}, h$) 
2: generate $\tilde{T}$ by calling MMG with the input mesh $\mathcal{T}$ and the vertex mesh size $h$
3: return $\tilde{T}$
4: procedure GENERATE_MESH_SIZES($\mathcal{T}, \eta, \theta, \rho$) 
5: Let $n_v$ denote the number of vertices of $\mathcal{T}$
6: zero initialize arrays $\eta$ and $h$ of size $n_v$
7: for each mesh element $K \in \mathcal{T}$ do
8: for each element vertex $a \in \mathcal{V}_K$ do
9: $\eta[a] = \eta[a] + \eta_K$
10: $h[a] = \max(h[a], h_K)$
11: sort the vertices in an array ord such that $\eta[\text{ord}[j]]$ is non-decreasing
12: find the smallest integer $n \in \{1, \ldots, n_v\}$ such that $\sum_{j=1}^n \eta[\text{ord}[j]]^2 \geq \theta \sum_a \eta[a]^2$.
13: for $j = 1, \ldots, n$ do
14: $h[\text{ord}[i]] = \rho h[\text{ord}[i]]$
15: return $h$
16: procedure ADAPTIVE_LOOP($\mathcal{T}^{(0)}, \ell_{\max}, \theta, \rho$) 
17: for $\ell = 0, \ldots, \ell_{\max}$ do
18: assemble the finite-element matrix associated with $\mathcal{T}^{(0)}$
19: solve the linear system with MUMPS
20: compute the estimator $\eta$
21: compute the new mesh sizes $h = \text{GENERATE_MESH_SIZES}($\mathcal{T}^{(\ell)}, \eta, \theta, \rho$)$
22: generate the new mesh $\mathcal{T}^{(\ell+1)} = \text{GENERATE_MESH}($\mathcal{T}^{(\ell)}, h$)$

that contribute to 5% of the total squared error, and that these elements have their diameter divided by two.

4.1.6. Error measurements. The analytical solutions for the examples below are not available, which complicates the numerical validation of the proposed error estimator. For a given mesh and polynomial $p$, if $(E_h, J_h)$ denotes the computed discrete solution, we compute a “reference” solution $(\tilde{E}_h, \tilde{J}_h)$ on the same mesh with $p = p + 2$. We then employ the quantities

$$\xi_K := \frac{\| (\tilde{E}_h - E_h, \tilde{J}_h - J_h) \|_K}{\sum_{K\in\mathcal{T}_h} \xi_K^2} \quad \xi^2 := \sum_{K\in\mathcal{T}_h} \xi_K^2$$

to obtain a measure of the discretization error.

4.1.7. Comparison with uniform meshes. We also benchmark the adaptive process against uniform meshes. To this end, we build for each geometry of interest a sequence of uniform meshes with MMG by simply requiring a maximal allowed mesh size. The mesh size is chosen so that the resulting number of degrees of freedom is similar to the structured meshes produced by the adaptive algorithm. This enables to quantify the accuracy improvement due to local refinements, since roughly the same computational cost is then required for the structured and the unstructured meshes. To avoid any confusion, we employ below the notation $\xi_u$ and $\eta_u$ for the error and estimator computed with the uniform meshes, while the quantities $\xi_a$ and $\eta_a$ relate to the adaptive meshes.
4.2. **Gold bowtie antenna.** Our first example is a bowtie nano-antenna made of gold, as depicted on Figure 1. The incidence angle is \( \theta = \pi/3 \), and thus \( \mathbf{d} = (\cos \theta, \sin \theta) \) and \( \mathbf{p} = (-\sin \theta, \cos \theta) \). We consider three frequencies, namely \( \omega = 0.8\omega_P \), \( 0.9\omega_P \) and \( \omega_P \). Figure 2 presents the reference solution computed on the finest mesh. The case where \( \omega = \omega_P \) is of particular interest: it can been seen on Figure 2 that the desired light-focusing effect is effectively achieved.

We start the adaptive loop with the initial mesh on the right panel of Figure 1 and run this loop for 80 iterations with the polynomial degree \( p = 1 \). Figure 3 depicts the behaviour of the errors \( \xi_a \) and \( \xi_u \) plotted against the number of degrees of freedom \( N_{\text{dofs}} \). The accuracy is significantly improved on adaptive meshes for a similar number of degrees of freedom. Besides, we observe the optimal convergence rate in \( N_{\text{dofs}}^{-(p+1)/2} \), which means that the estimator correctly steers the mesh refinement process. Figure 4 shows the effectivity index of the estimator for both adaptive and uniform meshes. The effectivity index first oscillates before stabilizing asymptotically for fine meshes. This behaviour is typical of non-coercive problems [6]. It is also in agreement with efficiency estimate (3.21) of Theorem 3.10 which states that the estimator may become inefficient on coarse meshes. Finally, we present the elementwise actual error distribution and the estimator \( \eta_K \) in the central region of the mesh for \( \omega = 0.8\omega_P \) in Figure 5. While the scales of the left and right panels are different, the (relative) agreement between the actual error and the estimator is excellent.

4.3. **Silver nanotip.** Here, we model the silver nanotip depicted on the left panel of Figure 6. We consider three frequencies of interest, namely \( \omega := 0.7\omega_P \), \( \omega_P \) and \( 1.3\omega_P \). In every case, we select an incident planewave with direction \( \mathbf{d} = (1, 0) \), and polarization \( \mathbf{p} = (0, 1) \), and we begin the adaptive algorithm on the initial mesh represented in the right panel of Figure 6. The discrete solution is computed with a polynomial degree \( p = 2 \) and we run the adaptive loop for 50 iterations. The reference solutions computed on the finest meshes are presented in Figure 7.

Figure 8 shows the convergence history for adaptive and uniform meshes. The adaptive meshes drastically improve the accuracy, and yield the optimal convergence rate \( N_{\text{dofs}}^{-(p+1)/2} \).
The case where $\omega = 0.7\omega_P$ is particularly instructive, since uniform meshes clearly converge suboptimally. We present the effectivity indices in Figure 9. As previously stated, we observe a usual behaviour, which is in agreement with previous works and our key theoretical results. In Figure 10 we represent the elementwise error distribution and the estimator in a neighborhood of the nanotip at iteration #25 of the adaptive algorithm. We observe a nice agreement between the estimator and the actual error for the selected frequencies. Finally, Figure 11 features the final mesh produced by the adaptive algorithm at the last iteration (#50). The meshes are finer close to the inclusion, with specific refinements close to the edges and corners of the tip, as to be expected.

4.4. Gold V-groove channel. The last example is a section of a “V-groove” channel depicted in Figure 12. The incidence angle is again $\theta = \pi/3$, with $d = (\cos \theta, \sin \theta)$ and $p = (-\sin \theta, \cos \theta)$. The reference solutions produced on the finest meshes are presented
in Figure 13 for $\omega = 0.8\omega_p$, $0.9\omega_p$ and $\omega_p$. The desired behaviour is observed in the case $\omega = 0.9\omega_p$ where the electric field is localized in the “V” cavity, which can be used to design a waveguide along the transverse direction. We run the adaptive loop for 50 iterations starting with the initial mesh of Figure 12 and $p = 3$.

As in the other experiments, Figure 14 presents the behaviour of the actual error against the number of degrees of freedom, and we observe a large accuracy enhancement on adaptive meshes, together with an optimal convergence rate. The effectivity indices are represented on Figure 15. They exhibit a nicer behaviour than in the previous experiments. This is linked to the fact that a higher polynomial degree is employed with similar starting mesh sizes, which shorten the “pre-asymptotic regime” where the reliability constant may depend on the mesh size. Figure 16 shows the actual and estimated error distributions are very similar, again illustrating the quality of the proposed estimator.

5. Conclusion

We propose a novel residual-based a posteriori error estimator for finite element discretizations of Maxwell’s equations coupled with a non-local hydrodynamic Drude model taking into account spatial dispersion effects in metallic nanostructures. At the theoretical level, we
Figure 4. Effectivity indices in the bowtie example

(A) $\omega = 0.8\omega_p$

(B) $\omega = 0.9\omega_p$

(C) $\omega = \omega_p$

Figure 5. Actual (left panel) and estimated (right panel) errors at the iteration #80 of the adaptive algorithm for the bowtie antenna example with $\omega = 0.8\omega_p$. 
establish reliability and efficiency of the estimator. We also propose a number of relevant two-dimensional examples where the error estimator drives an adaptive procedure. We observe the expected optimal convergence rate meaning that the estimator correctly steers the adaptive process. Besides, the adaptive algorithm enables substantial computational savings, as compared to the use of uniform meshes. These preliminary results are very promising, and future work will focus on more realistic three-dimensional benchmarks.
