Abstract

Agar, carrageenan and alginate are high valued seaweed polysaccharides, which are used as gelation and thickening agents in different food, pharmaceutical and biotechnological industries. The annual global production of the polysaccharides has recently reached 100,000 tons with a gross market value just above US$ 1.1 billion. In Sri Lanka although several seaweed species are available, there is no systematic study on comparison of method of extraction, yield and physicochemical properties of polysaccharides from seaweeds. Seaweed species Gracilaria edulis, Gracilaria verrucosa, Kappaphycus alvarezii and Sargassum wightti were collected from North and South coast of Sri Lanka. Gracilaria edulis and Gracilaria verrucosa were used for agar extraction with acid and alkaline treatments. Carrageenan was extracted from Kappaphycus alvarezii using alkaline treatments. Three types of carrageenan (kappa, iota, lambda) were separated using freeze thawing, jelly pressing and alcohol precipitation methods respectively. For the extraction of alginates from Sargassum wightti samples were treated with acid and alkaline and hot and cold extraction methods were used. Some of the above physicochemical properties were compared with commercial available products.

In agar yield (16.6%) of acid treated Gracilaria edulis was high when compared to Gracilaria verrucosa. The gel strength was high in alkaline treatments (429 g/cm²) and was obtained from G. verrucosa. Freeze thawed method gave the highest yield (23.4%) and gel strength 715 g/cm² in kappa carrageenan extracts. The highest alginate yield (35%) was obtained from Sargassum wightti in hot extraction treatments. The mean viscosity of agar and carrageenan purchased from commercially and extracted polysaccharides didn’t show significant difference. When considered the proximate composition mean crude protein contents of extracted and commercial products were not significantly different on dry weight basis among agar, carrageenan and alginates. The mean value of iodine content of extracted and commercial product obtain from agar carrageenan and alginates were range from 32-58; 26-45 and 43-57 mg/l respectively. The mean sodium content of agar, carrageenan and alginates were significant difference between extracted polysaccharides and commercial product. There is also significant difference in the calcium contents of agar, carrageenan and alginates respectively. Chemical properties of agar carrageenan and alginates extracted in laboratory were more superior when compared to those properties of the products collected from the local market, but physical properties were at comparable levels. Considering the above extracted product can be promoted for commercial market.

Keywords: Polysaccharides; Agar; Carrageenan; Alginates; Extraction; Seaweeds

Introduction

Agar, carrageenan and Alginates are industrially important hydrocolloids derived from brown and red seaweeds. These hydrocolloid polysaccharides are of significant importance, both technologically and economically. They are used in the food, pharmaceutical, medicinal, and biotechnological industries due to their distinct physical-chemical properties as gelling agents, thickeners or stabilizing and emulsifying agents. Agar and carrageenan constitute of two well defined families of polysaccharide, derived from different genera in the Rhodophyta (red algae), Phaeophycya (Brown algae) collectively known as Agarophyta, Carrageenophyta and Alginophyta [1]. These seaweed polysaccharides have a high nutritional property than other natural hydrocolloids such as pectin, xanthan gum [2]. These hydrocolloids have a global commercial value of approximately US$ 1.1 billion, which is prospected to increase [3]. Seaweeds have a unique source of high-value hydrocolloid polysaccharides: whereas Carrageenans currently have the highest commercial total production (60,000 ton/year) and contribute to the highest total value of US$ 626 million per year.

This paper, reports the distinctive techniques for extraction of agar carrageenan and alginates together with physical substance and wholesome properties from locally accessible species. Agar was extracted from Gracilaria verrucosa and Gracilaria edulis by alkali and acid treatment and carrageenan from Kappaphycus alvarezii and alginate was obtained from two Sargassum species. The high qualities of end products were compared with each commercially available polysaccharide.

Material and Method

Sample collection and preparation

Seaweed species Gracilaria verrucosa and Gracilaria edulis were collected from coastal areas of Trincomalle and Kalpitiya. Kappaphycus alvarezii was collected from North West coastal belt of Sri Lanka. Two...
species of brown seaweeds, Sargassum wightii and Sargassum filipendula were collected from Southern cost of Sri Lanka. The specimens were transported to the research facility, kept in ice and washed a few times in running water to expel epiphytes and dried in an air coursed broiler. Suitable measures of the dried examples were taken, ground utilize a household processor and kept in plastic holder secured with aluminum foils. Tests were kept at 0°C for further investigation.

**Extraction of agaro-phycytes**

The dried powdery samples of two seaweeds species Gracilaria edulis and Gracilaria verrucosa were used with two different methods pretreated with acid [4] and alkaline (Tomas & Krishnamurthy, 1976.) to extract dried agar powder. Then 1.5% of agar solution was prepared by boiling 9 g of agar powder in 600 ml of distilled water for 30 min. Viscosity, gel strength and gel pH were measured in prepared solution. Viscosity of the solution was determined at 80°C by using a Brookfield viscometer (BL spindle at 60 rpm, Tokyo Keiki) according to Joint FAO/WHO Expert Committee [5]. The filtrate was gelled at room temperature, kept at 20°C for 15 h and used to determine gel strength (3 replicates per sample), using a 1 cm² plunger (Nikkansui Shiki Gelometer, Kiya Seisakusho, Tokyo) according to Nikan S.(1988). The solidagar was cut into strips, frozen at -18°C for 24 h, thawed in tap water, soaked in ethanol and dried at 40°C in an oven for determination of agar yield.

**Extraction of carrageenoppytes**

50 g of dried material of Kappaphycus alvarezii was washed with tap water to remove sand and salt. The three carrageenan extraction methods, freeze thawed, gel pressing and alcohol precipitation were done according to [6]. The extracted dried powder was stored and kept at 0°C in polythene bags until further analysis. Then 1.5g carrageenan solution was prepared from 9 g of the extract, dissolved in 600 ml of distilled water which was heated at 80°C for 30 min. The viscosity of this solution was measured at 75°C using a Brookfield type viscometer (Tokyo Keiki). To measure gel strength of the solution, 0.29g of KCl was added and gel was maintained at room temperature. For kappa carrageenan analysis the gel was incubated at 20°C and for iota carrageenan incubation was done at 10°C, for a period of one hour. (3 replicates per sample)

**Extraction of algino-phycytes**

50 g of dried material of Sargassum wightii and Sargassum filifendinalis were washed with tap water to remove sand, salt, mud and dirt. Alginate was extracted according to four different methods. Alginate yield was measured by method A was performed according to [7] method B [8] and method C were done in hot and cooled methods [9]. The extracted dried powder was stored and kept in 0°C in polythene bags until further analysis. The intrinsic viscosity measurement for alginate sample were carried out at 25°C for 0.4% alginate in NaOH as solution with glass viscosity meter and Molecular weight was calculated using Mark Houwink Sakurada equation $\eta = k M^\alpha$. [10].

**Determination of chemical physical and nutritional parameters of polysaccharides**

The method which gave highest yield was followed to extracted agar, carrageenan and alginic acid and samples from the above were subjected to compare physical and chemical parameters with market available products. The fat content, protein content, carbohydrate content, moisture content and ash content [11] were analyzed according to given procedures. Micro and macro elements were measured according to [12] method using atomic absorption spectrophotometer. The gel pH was measured using electronic pH meter. The melting point was determined according to [13] and gelling points from [14].

**Results and Discussion**

**Effect of different extraction methods on quality of seaweed polysaccharides**

**Quality Index of Gracilaria verrucosa and Gracilaria edulis:** The variation in quality of five different seaweed species such as Gracilaria verrucosa, Gracilaria edulis, Sargassum wightii, Sargassum species and Kappaphycus alvarezii showed in Table 1. Statistical analysis of data showed that there were no significant differences among moisture percentage and purity percentage of agaro-phycytes. The highest percentage of total impurities (TI) (26.34 ± 1.2) was recorded in Sargassum species. The highest percentage of DDMS (12.8 ± 0.23) was recorded in Kappaphycus alvarezii and lowest percentage of DDMS (10.7 ± 0.77) was recorded in Sargassum wightii. The Gracilaria verrucosa also recorded high percentage of insoluble matters (20.22) low percentage of total soluble matters (11.34%). The highest percentage of total soluble matter (12.79%) was recorded in Sargassum species. But all the species used showed a high amount of purity. Gracilaria verrucosa recorded highest purity percentage (98.73%) leading to best quality carrageenan.

**Effect of different extraction methods on quality of agar**

Comparison of the Physical properties of agar extracted from G. verrucosa and G. edulis pretreated with alkaline and acids is showed in Table 2. The viscosity of crude agar extracted from G. edulis was 150 cp which is significantly higher than that of G. verrucosa. In acid treatment viscosity increase to 195 cp and alkaline treatment to 120 cp where the viscosity of crude extract was 90.5 cp. This shows that there is a significant increase in viscosity when acid treatment is used. In commercial agar viscosity recorded was 150 cp which is significantly higher than that of G. verrucosa. In acid treatment viscosity increase to 195 cp and alkaline treatment to 120 cp where the viscosity of crude extract was 90.5 cp. This shows that there is a significant increase in viscosity when acid treatment is used. In commercial agar viscosity recorded was 150 cp which was similar to value recorded in crude extract for G. edulis. Pretreatment of acid improve significantly the viscosity of both species leading to better thickening ability.

| Species              | Moisture (%) (mean ± S.E) | Total soluble matter (%) (mean ± S.E) | Insoluble matter (%) (mean ± S.E) | DDMS (mean ± S.E) | Purity (mean ± S.E) | Total impurities (%) (mean ± S.E) |
|----------------------|---------------------------|---------------------------------------|-----------------------------------|-------------------|-------------------|----------------------------------|
| Gracilaria verrucosa | 12.37 ± 0.07               | 11.58 ± 4.6                            | 20.22 ± 5.9                       | 12.70 ± 4.8       | 98.73 ± 6.2       | 26.34 ± 1.2                      |
| Gracilaria edulis    | 12.37 ± 0.56               | 12.97 ± 7.8                            | 11.34 ± 0.02                      | 9.67 ± 2.3        | 98.66 ± 6.6       | 23.38 ± 1.5                      |
| Sargassum wightii    | 13.7 ± 0.12                | 12.7 ± 6.9                             | 15.8 ± 0.04                       | 10.7 ± 0.77       | 95 ± 6.9          | 25 ± 2.9                        |
| Sargassum species    | 14.7 ± 1.78                | 10.9 ± 1.2                             | 17 ± 1.3                          | 12.3 ± 0.8        | 96.7 ± 4.2        | 22 ± 1.2                        |
| Kappaphycus alvarezii | 14.5 ± 1.98               | 12.7 ± 2.9                             | 14 ± 0.9                          | 12.8 ± 0.23       | 97 ± 2.8          | 22 ± 0.2                        |

Table 1: Comparison of physical quality parameters in purity%, DDMS%, moisture%, total soluble matter (%) and insoluble matter (%) in five different seaweed species from Sri Lanka.
The pH values of crude, acid and alkaline treated agar extracted from *Gracilaria verrucosa* and *Gracilaria edulis* species were 6.27, 6.3, 4.3, 4.25, 8.3 and 8.67 respectively.

Extracts from *Gracilaria verrucosa* and *Gracilaria edulis* treated with acid gave lower gel strength when compared to alkaline treated samples. The crude agar from *G. verrucosa* and *Gracilaria edulis* showed the highest gel strength when compared acid and alkaline treated (1.5%) gel indicating 450 g/cm², 482 g/cm² respectively. Agar extracted from alkaline treated *Gracilaria verrucosa* showed an increase in the gel strength by 60% when compared to acid treated once. The commercial agar showed two fold higher gel strength than crude agar. In wild or older plants in *Gracilaria* species, agar gel strength is higher than that of younger or cultivated plants [15].

With respects to yield, agar extracted from *Gracilaria verrucosa* was recorded the lowest yield (15.6%). The yield recorded for the alkaline treated of *Gracilaria verrucosa* and *Gracilaria edulis* were 18.6% and 20.5% respectively. Acid treated *Gracilaria edulis* significantly increases agar yield from 77% to 80% when compared to alkaline treatments. These observations of present study are similar to the [16] who states that the acid treated wild samples give highest agar yield due to higher hydrolysis of the seaweed in acid than in alkaline. *Gracilaria species* which was used as a raw material for agar extraction generally give a yield of 10-25% [17].

There was increased in melting point by 15% in *Gracilaria verrucosa* and 4% in *Gracilaria edulis* of agar extracted using alkaline treatments. The melting point of agar extracted from alkaline treated *Gracilaria edulis* increased by (26%) when compared to acid treated agar. Highest gelling point (43°C) was observed for acid treated agar extracted from *G. verrucosa* where there was increased by (34%) when compared to alkaline treatments. The time taken for alkaline treatment has improved the gelling point from 32°C to 43°C in *Gracilaria verrucosa* [18]. States that gelling point change with the variation of alkaline strength and also with treatment time.

The carrageenan extracted from *Kappaphycus alvarezi* (Eucheema cottani) is referred to as kappa carrageenan while *Eucheema spinosa iota* carrageenan [3]. In the present study was used *Kappaphycus alvarezi*. The carrageenan yield ranged from 29.70-37.3%. The gel pressing method gave the lowest yield (29.7%) whereas freeze thawed method gave the highest yield.

The viscosity of alcohol precipitation method was the highest (240 cp) while freeze thaw method showed second highest value (180.2 cp). The lowest value of 70.2 cp was obtained from gel pressing method. The commercial product showed 250 cp which is closer to the viscosity of alcohol precipitation method of carrageenan extracted in the present study (Table 3).

The gel strength of kappa carrageenan was highest in freeze thaw method and was 715 g/cm². The lowest gel strength (150 g/cm²) was obtained from gel pressing method while second highest value (680 g/cm²) was record for alcohol precipitation method.

The melting point of carrageenan was in (95°C) in freeze thaw method while it was lower than that of alcohol precipitation and gel pressing method.

### Alginic acid extraction methods

The yield and apparent viscosity of alginates extracted of two different brown seaweeds using four different extraction methods showed in Table 4. The alginates from *Sargussum wightti* from hot extraction (method C) gave the highest alginic yield (47.3%) and viscosity (120 cp) when compared to other three methods. Cold extraction method C showed its second highest yield 44.43% in *Sargussum wightti*. In the hot extraction which was soaked in 1% CaCl₂ at 50°C for three hours resulted in higher yield than overnight at 27°C in cold method. The similar trend was observed in *Sargussum filipendula* gave highest alginic yield (40.5%) from hot method. The lowest alginates yield (19.3%) was observed in method B where given in Table 5 in *Sargussum wightti*.

The apparent viscosity of *Sargussum wightti* dropped significantly from 120 cp to 99 cp when it was extracted through hot method. Similar trend was observed for *Sargussum filipendula*. The apparent viscosity of alginates and for extraction method depended on species used for extraction of alginates. However it was also observed that the

| Species | Crude extract Mean ± S.E | Acid treatment, (1.5% agar gel) Mean ± S.E | Alkaline treated agar (1.5% agar) Mean ± S.E |
|---------|--------------------------|------------------------------------------|--------------------------------------------|
| Gracilaria verrucosa | 90.5 ± 0.091 | 150 ± 1.37 | 195.27 ± 0.61 |
| Gracilaria edulis | 450 ± 4.5 | 375 ± 0.76 | 65 ± 1.0 |
| Physical Properties | 15.5 ± 0.4 | 16.6 ± 0.9 | 33 ± 0.069 |
| Viscosity (cp) | 715.0 ± 4.54 | 70.50 ± 2.81 | 75°C ± 0.73 |
| Gel strength g/cm² | 37.3 ± 0.2 | 90°C ± 0.08 | 92.6°C ± 0.154 |
| Yield (%) | 50°C ± 0.6 | 75°C ± 0.7 | 94.5°C ± 0.02 |
| Melting point °C | 95°C ± 0.23 | 30°C ± 0.05 | 32°C ± 0.23 |
| Gelling point °C | 150 ± 0.7 | 30°C ± 0.01 | 30°C ± 0.1 |
| Alcohol precipitation, 1.5% gel | 130.5 ± 1.3 | 40°C ± 0.3 |

Table 2: Comparison of physical properties of agar extracted from *Gracilaria verrucosa* and *Gracilaria edulis* using different method.

| Physical properties | Freeze thaw method | Gel pressing, 1.5% gel | Alcohol precipitation, 1.5% gel |
|---------------------|---------------------|------------------------|-------------------------------|
| Viscosity (cp) | 80.2 ± 4.5 | 150 ± 0.71 | 130.5 ± 1.3 |
| Gel strength g/cm² | 715.0 ± 4.54 | 70.50 ± 2.81 | 680 ± 13.5 |
| Yield (%) | 37.3 ± 0.2 | 29.7 ± 0.26 | 30.5 ± 0.26 |
| Gelling point °C | 50°C ± 0.6 | 43°C ± 0.56 | 40°C ± 0.3 |
| Melting point °C | 95°C ± 0.23 | 65°C ± 0.7 | 75°C ± 2.9 |

Table 4: Effect of different extraction methods on yield and viscosity of alginates extracted from Sargussum wightti and Sargussum filipendula.

| Experimental methods | Treatments and digestion | Precipitation |
|----------------------|--------------------------|---------------|
| Method A             | 0.4% formaldehyde 5 hours, 2N HSO₄ at 27°C overnight, 1% NaCO₃, 27°C overnight, 50ml added NaCl 1% (nnv) | Ethanol, 50°C for 24 hours drying |
| Method B             | Boiling water for 30 min, 0.5% CaCl₂ (100°C) 30 minutes, NaCl 10% of weed (100°C) 30 minutes, 10% of weed NaNO₃ (90°C) for 20 minutes | Dilute H₂SO₄, 90°C for 2 hours drying |
| Method C (hot)       | Soaked 1% CaCl₂ (50°C) three hours 5% HCl (1 hour), 3% NaC₃O₃ for 1 hour (27°C) | Ethanol/water (1:1, w/v), 50°C for 24 hours drying |
| Method C (cold)      | Soaked 1% CaCl₂ (27°C) over night 5% HCl (1 hour), 3% NaC₃O₃ for 1 hour (27°C) | Ethanol/water (1:1, w/v), 50°C for 24 hours drying |

Table 5: Summary of experimental design of the four alginate extraction methods.

| Methods | Parameter | Intrinsic viscosity (η) (dLg⁻¹) | Molecular weight Mₙ x 10⁵ |
|---------|-----------|---------------------------------|--------------------------|
|         |           | Hot method | Cold method | Hot method | Cold method |
| Species |           |             |             |             |             |
| Sargussum wightti | | 8.3 ± 0.28 | 14.6 ± 0.63 | 6.8 ± 0.26 | 7.3 ± 0.25 |
| Sargussum filipendula | | 4.3 ± 0.08 | 12.0 ± 0.63 | 4.8 ± 0.25 | 5.9 ± 0.26 |

Table 6: Intrinsic viscosity and Molecular weight of alginates sample extracted from two different species.

Application of concentrated H₂SO₄ for overnight in method a lead to loss of alginates viscosity.

The intrinsic viscosity of alginate from Sargussum wightti significantly increased by 71% in cold method when compared to hot method. The similar changes was observed in intrinsic viscosity of alginates from S. filipendula where significant increased by heat treatments from 4.3 to 12.0. Sargussum wightti was more heat sensitive when compared to Sargussum filipendula.

The calculated molecular weight (Mₙ) of alginates extracted from Sargussum wightti was given in Table 6. Alginates extracted from Sargussum wightti has highest molecular weight (7.3 g mol⁻¹) in cold extraction and 6.8 g mol⁻¹ in hot extraction. Sargussum wightti was found more heat sensitive when compared to Sargussum filipendula. It is apparent that due to the hot extraction of molecular weight get dropped from 7.3 to 6.8 when compared to cold extraction method. Species Sargussum wightti and Sargussum filipendula showed a similar changes.

When consider the protein content Table 7 of extracted agar (6 ± 0.35) at lower than that in extracted carrageenan (8.2 ± 0.3). The protein value of extracted polysaccharides were found higher than that of commercial products except in alginic acid. Commercial agar was reports significantly lowest (p>0.05) protein value (4.3 ± 0.08)%

The fat content of the different polysaccharides of majority of extracted products have lower fat content. The extracted carrageenan have highest fat content (2 ± 1%) while commercial carrageenan gave the lowest fat contents (0.25 ± 0.23%). It was resulted that industrial polysaccharides have lowest fat content where incomparrable to extracted polysaccharides.

As given in Table 7, all the polysaccharides have higher carbohydrate content, more than 40%. In the extracted alginic acid gave the highest carbohydrate value (60 ± 1.7%) while lowest value was indicated in commercial alginic acid. The carbohydrate contents of extracted polysaccharides were found statistically higher than commercial products except in carrageenan.

The ash content of the laboratory prepared polysaccharides ranged from 2.5 ± 0.03% to 4.28 ± 2.31% which is higher when compared to the commercial products. All commercially extracted polysaccharides, agar and carrageenan ranged from 2.5 ± 0.03 to 2.7 ± 0.03%. Differences were found to be statistically significant. Generally market product indicate low ash content and laboratory extracts gave high ash content. Their high mineral content may be due to different treatments and purification process adapted.

The extraction process of polysaccharides depend on specific seaweed species [19], but generally consists of laboratory agar extracted using alkali treatment from Gracilaria verrucosa followed by hot water extraction. The gel strength of commercial agar was two times higher than laboratory extracted agar.

Viscosity was highest (150 ± 5.4) in laboratory prepared agar than in commercial product. Alkaline treatments improved the melting points 83°C ± 1.35, but lower than that of commercial agar. The lowest gelling point was observed for laboratory prepared agar when compared to commercial agar, carrageenan extraction from alkaline (6% KOH) treatments improved gel strength two fold than in commercial carrageenan. As described above, for carrageenan the alkali treatments causes a chemical change in agar (formation of the 3,6-anhydro-galactopyranosyl) resulting in increased gel strength. The viscosity of laboratory prepared carrageenan was highest than commercial product Table 8.

The gelling point was higher in commercial carrageenan while melting point in both carrageenan types were lower than that of agar.

Table 9 indicates the mineral composition of three different seaweed extracts and commercial product. The commercial agar had

| Parameter/Methods | Yield (%) | Viscosity Cp |
|-------------------|-----------|--------------|
|                   | Method A  | Method B     | Method C     |
|                   | (mean ± S.E.) | (mean ± S.E.) | (mean ± S.E.) |
| Species Sargussum wightti | 33 ± 0.225 | 22.02 ± 0.56 | 47.3 ± 1.2 |
| Sargussum filipendula | 27 ± 0.56 | 19.3 ± 0.43 | 40.5 ± 0.67 |

| Experimental methods | Treatments and digestion | Precipitation |
|----------------------|--------------------------|---------------|
| Method A             | 0.4% formaldehyde 5 hours, 2N HSO₄ at 27°C overnight, 1% NaCO₃, 27°C overnight, 50ml added NaCl 1% (nnv) | Ethanol, 50°C for 24 hours drying |
| Method B             | Boiling water for 30 min, 0.5% CaCl₂ (100°C) 30 minutes, NaCl 10% of weed (100°C) 30 minutes, 10% of weed NaNO₃ (90°C) for 20 minutes | Dilute H₂SO₄, 90°C for 2 hours drying |
| Method C (hot)       | Soaked 1% CaCl₂ (50°C) three hours 5% HCl (1 hour), 3% NaC₃O₃ for 1 hour (27°C) | Ethanol/water (1:1, w/v), 50°C for 24 hours drying |
| Method C (cold)      | Soaked 1% CaCl₂ (27°C) over night 5% HCl (1 hour), 3% NaC₃O₃ for 1 hour (27°C) | Ethanol/water (1:1, w/v), 50°C for 24 hours drying |
the lowest Na content. On the other hand, alginic acid has significantly high sodium content (16944 ± 64.71). Carrageenan showed the second highest sodium contents (9786 ± 9.9 mg/kg).

The Mg content and in the commercial products were in the range of 400 ± 6.1 to 750 ± 47.4 mg/kg. The level of Mg content among laboratory prepared extracts did not significantly differ (p<0.05). The highest Mg values were found in agar and carrageenan (5901 ± 5.7 to 49947 mg/kg). The lower Mg levels present could be attributed to the fact that elements Mg have destroyed during processing.

The commercial agar, carrageenan and alginic acid tend to have a lower Ca content when compared to the laboratory prepared products. The highest Ca content was observed extracted agar 79018 ± 29.08. The second highest Ca content (8222 ± 37.62) in carrageenan indicating significantly higher amount to the commercial product. It is possible that variation in method which carried out in commercial and laboratory prepared seaweed extracts should have contributed to the differences observed.

All the polysaccharides recorded very low Mn except in alginic acid which have the highest Mn content among them (15 ± 0.29). There was a statistically significant difference among Mn values (p<0.05) in commercial and laboratory prepared products. The differences in the Mn content of seaweed extracts could be traced to the possible indigestion of Mn during processing.

When consider the potassium content carrageenan tends to have lower levels 49947 mg/kg. However the second highest value of potassium was recorded in agar (15397 ± 56.9 mg/kg) which was significantly different when compared to the value of potassium in carrageenan. When consider the agar, carrageenan and alginic acid content of commercial product is range from 1100 ± 47.4 mg/kg which exhibited low potassium content than laboratory prepared seaweed extracts.
products. The carrageenan and agar were higher in potassium due to available considerable amount of potassium in raw seaweeds.

Iodine level was found significantly higher in laboratory prepared products when compared to the commercial ones. In the study laboratory prepared ones were rich source of iodine when compared to the others. The reason for differences in iodine content between commercial and laboratory products may be due to the differences in the processing techniques. These products can be extensively used as health food.

There were no significant differences between sulfate content of commercial extracts and laboratory prepared ones. The sulfate content ranged from 6 ± 20 mg/kg. The low sulfate content observed may be due to the sulfate degradation due to different bonds formation during processing.

Conclusion

Seaweed is a unique source of valuable hydrocolloids due to their functional properties and have a significant importance in the food, medicinal, and biotechnological industries. In order to improve the functional properties of these hydrocolloid polysaccharides to need identify the sustainable use of chemicals and more selective extractions techniques.

Current literature mainly focuses on hydrolysis of the hydrocolloid agar, two seaweed specific by acid and alkaline have been identified which degrade the hydrocolloid polysaccharides and thereby change the yield and gel strength of agar. Physical properties of agar extracted from Gracilaria verrucosa treated with alkaline was more superior to agar extracted from Gracilaria edulis. The physical properties of extracted seaweed hydrocolloids are comparable to commercial hydrocolloid. In addition to extracted hydro collided has superior nutritional properties than commercial products could be demanded substitute in food industry.

Alkaline treatments increased the carrageenan properties such as gel strength, while maintaining the gelling properties and others decreased the hydrocolloid yield and viscosity interfered with the gelling abilities of the hydrocolloids. Acid treatments increased the hydrocolloid yield and viscosity and decreased the gel strength. The high viscosity hydrocolloid has demand for the food industry and low viscous hydrocolloids are demand in textile industry.

Sargassum wightii found to be very heat sensitive than Sargassum filipendula gave significant higher yield of alginate by the hot extraction at 50°C compare to other methods. The effect of heat on the extent of depolymerisation of the alginate molecular weight and viscosity from the two brown seaweed species was significant. The properties of these hydrocolloids could be controlled by pre heat treatments in order to full fill the requirement of industry what used application these polysaccharides. Thus the alginates extracted from Sri Lankan seaweeds species has a potential to be used in relevant industries considering to its yield, viscosity and molecular weight.
