A Topos Perspective on the Kochen-Specker Theorem: 
III. Von Neumann Algebras as the Base Category

Abstract

We extend the topos-theoretic treatment given in previous papers [1, 2] of assigning values to quantities in quantum theory, and of related issues such as the Kochen-Specker theorem. This extension has two main parts: the use of von Neumann algebras as a base category (Section 2); and the relation of our generalized valuations to (i) the assignment to quantities of intervals of real numbers, and (ii) the idea of a subobject of the coarse-graining presheaf (Section 3).

1 Introduction

Two previous papers—hereafter referred to as [1, 2]—have developed a topos-theoretic perspective on the assignment of values to quantities in quantum theory. In particular, it was shown that the Kochen-Specker theorem (which states the impossibility of assigning to each bounded self-adjoint operator on a Hilbert space of dimension greater than 2, a real number, such that functional relations are preserved) is equivalent to the non-existence of a global element of a certain presheaf $\Sigma$, called the ‘spectral presheaf’, defined on the category $\mathcal{O}$ of bounded self-adjoint operators on a Hilbert space $\mathcal{H}$. In particular, the Kochen-Specker theorem’s $\textit{FUNC}$ condition—which states that assigned values preserve the operators’ functional relations—turns out to be equivalent to the ‘matching condition’ in the definition of a global section of the spectral presheaf. It was similarly shown that the Kochen-Specker theorem is equivalent to the non-existence of a global element of a presheaf $\mathcal{D}$—called the ‘dual presheaf’—defined on the category $\mathcal{W}$ of Boolean subalgebras of the lattice $\mathcal{L}(\mathcal{H})$ of projectors on $\mathcal{H}$.

It was also shown that it was possible to define so-called ‘generalised valuations’ on all quantities, according to which any proposition “$A \in \Delta$” (read as saying that the value of $A$ lies in the Borel set of real numbers $\Delta$) is assigned, in effect, a set of quantities that are coarse-grainings (functions) of $A$. To be precise, it is assigned a certain set of morphisms in the category $\mathcal{O}$ (or $\mathcal{W}$), the set being required to have the structure of a sieve. These generalised valuations obey a condition analogous to $\textit{FUNC}$, and other natural conditions. Furthermore, each (pure or mixed) quantum state defines such a valuation.

In this paper, we will extend this treatment in two main ways. The first corresponds to our previous concerns with the Kochen-Specker theorem and global sections, and with generalised valuations based on sieves. Thus, we will first discuss the issues adumbrated above, in terms of a base category different from $\mathcal{O}$ and $\mathcal{W}$: namely, the category $\mathcal{V}$ of commutative von Neumann subalgebras of an algebra of operators (Sections 2 and 3).

Second, we will further develop the idea of a generalised valuation (Section 4). In particular, we introduce the idea of an interval-valued valuation: at its simplest, the idea is to assign to a quantity $A$—not an individual member of its spectrum, as vetoed by the Kochen-Specker theorem—but rather, some subset of it. Though this idea seems at first sight very different from generalised valuations, that assign sieves to propositions “$A \in \Delta$”, we shall
see that the two types of valuations turn out to be closely related.

2 Von Neumann Algebras

2.1 Introducing \( \mathcal{V} \)

We will first rehearse the definitions given in the previous papers [1, 2], of the categories \( \mathcal{O} \) and \( \mathcal{W} \) defined in terms of the operators on a Hilbert space, over which various presheaves may be usefully constructed. Then we will introduce a new base category \( \mathcal{V} \) which has as objects commutative von Neumann algebras; and relate it to \( \mathcal{O} \) and \( \mathcal{W} \).

The categories \( \mathcal{O} \) and \( \mathcal{W} \) were defined as follows. The objects of the category \( \mathcal{O} \) are the bounded self-adjoint operators on the Hilbert space \( \mathcal{H} \) of some quantum system. A morphism \( f_\mathcal{O} : \hat{B} \rightarrow \hat{A} \) is defined to exist if \( \hat{B} = f(\hat{A}) \) (in the sense of [1] Eq. (2.4)) for some Borel function \( f \). This category is a preorder, and may be turned into a partially ordered set by forming equivalence classes of operators. Operators \( \hat{A} \) and \( \hat{B} \) are considered equivalent whenever they are isomorphic in the category \( \mathcal{O} \), i.e., when there exist some Borel functions \( f \) and \( g \) such that \( \hat{B} = f(\hat{A}) \) and \( \hat{A} = g(\hat{B}) \). The category obtained in this way is denoted \([\mathcal{O}]\).

The category \( \mathcal{W} \) is defined to have as its objects the Boolean subalgebras of the lattice \( \mathcal{L}(\mathcal{H}) \) of projectors on \( \mathcal{H} \). A morphism is defined to exist from \( \mathcal{W}_1 \) to \( \mathcal{W}_2 \) if, and only if, \( \mathcal{W}_1 \subset \mathcal{W}_2 \). Thus \( \mathcal{W} \) is just a partially ordered set (poset) equipped with the natural categorical structure of such a poset.

This category \( \mathcal{W} \) is related to \( \mathcal{O} \) via the covariant spectral algebra functor \( \mathcal{W} : \mathcal{O} \rightarrow \mathcal{W} \) which is defined as follows:

- On objects: \( \mathcal{W}(\hat{A}) := W_A \), where \( W_A \) is the spectral algebra of the operator \( \hat{A} \) (i.e., the collection of all projectors onto the subspaces of \( \mathcal{H} \) associated with Borel subsets of \( \sigma(\hat{A}) \)).

- On morphisms: If \( f_\mathcal{O} : \hat{B} \rightarrow \hat{A} \), then \( \mathcal{W}(f_\mathcal{O}) : W_B \rightarrow W_A \) is defined as the subset inclusion \( i_{W_B W_A} : W_B \rightarrow W_A \).

Note that operators in the same equivalence class in \([\mathcal{O}]\) will always have the same spectral algebra.

We now wish to introduce a new base category \( \mathcal{V} \) of commutative von Neumann algebras. We first recall (see e.g., [3]) a few facts about von Neumann algebras.
A (not necessarily commutative) von Neumann algebra $\mathcal{N}$ is a $C^*$-algebra of bounded operators on a Hilbert space $\mathcal{H}$ which is closed in the weak operator topology. The algebra $\mathcal{N}$ is generated by its lattice of projectors $\mathcal{L}(\mathcal{N})$, and is equal to its own double commutant, and to the double commutant of $\mathcal{L}(\mathcal{N})$:

$$\mathcal{L}(\mathcal{N})'' = \mathcal{N}'' = \mathcal{N}$$ (2.1)

The algebra contains all operators obtainable as Borel functions $f(\hat{A})$ of all normal operators $\hat{A} \in \mathcal{N}$.

We now define the category $\mathcal{V}$ associated with the Hilbert space $\mathcal{H}$ of some quantum system. The objects $V$ in $\mathcal{V}$ are the commutative von Neumann subalgebras of the algebra $B(\mathcal{H})$ of bounded operators on $\mathcal{H}$, and the morphisms in $\mathcal{V}$ are the subset inclusions—so if $V_2 \subseteq V_1$, we have a morphism $i_{V_2V_1} : V_2 \to V_1$. Thus the objects in the category $\mathcal{V}$ form a poset.

The category $\mathcal{V}$ is related to $\mathcal{O}$ via a covariant functor in a similar way to $\mathcal{W}$:

**Definition 2.1** The von Neumann algebra functor is the covariant functor $V : \mathcal{O} \to \mathcal{V}$ defined as follows:

- On objects: $V(\hat{A}) := V[A]$, where $V[A]$ is the commutative von Neumann algebra generated by the self-adjoint operator $\hat{A}$.

- On morphisms: If $f_O : \hat{B} \to \hat{A}$, then $V(f_O) : V[B] \to V[A]$ is defined as the subset inclusion $i_{V_BV_A} : V[B] \to V[A]$.

There is an even simpler relation between $\mathcal{W}$ and $\mathcal{V}$:

**Definition 2.2** The algebra generation functor is the covariant functor $V^W : \mathcal{W} \to \mathcal{V}$ defined as follows:

- On objects: $V^W(W) := W''$, where $W''$ is the double commutant of $W$ in the algebra $B(\mathcal{H})$ of all bounded operators on $\mathcal{H}$, so that $V^W(W)$ is the commutative von Neumann algebra generated by the projection operators in $W$.

- On morphisms: If $i_{W_2W_1} : W_2 \to W_1$ then $V^W(i_{W_2W_1}) : W_2'' \to W_1''$ is defined as the subset inclusion $i_{V_2V_1} : W_2'' \to W_1''$. 

3
The category $\mathcal{V}$ seems to give the most satisfactory description of the ordering structure of operators. In particular, there is no problem with isomorphic operators: any operator isomorphic to $\hat{A}$ will always be included in any subalgebra which contains $\hat{A}$. Also, each von Neumann algebra contains the spectral projectors of all its self-adjoint members; so in a sense $\mathcal{V}$ subsumes both $\mathcal{O}$ and $\mathcal{W}$.

Using $\mathcal{V}$ as the base category is also appealing, from an interpretative point of view. Many discussions and proofs of the Kochen-Specker theorem are written in terms of sub-algebras of operators and their relations.

### 2.2 Presheaves on $\mathcal{V}$

The spectral presheaf $\Sigma$ over $\mathcal{O}$ was introduced in [1]. We now define the corresponding presheaf over $\mathcal{V}$, and the state presheaf over $\mathcal{V}$.

1. **The Spectral Presheaf $\Sigma$**

We recall (see e.g., [3]) that the spectrum $\sigma(V)$ of a commutative von Neumann algebra $V$ is the set of all multiplicative linear functionals $\kappa : V \to \mathbb{C}$. Such a functional assigns a complex number $\kappa(\hat{A})$ to each operator $\hat{A} \in V$, such that $\kappa(\hat{A})\kappa(\hat{B}) = \kappa(\hat{A}\hat{B})$. If $\hat{A}$ is self-adjoint, $\kappa(\hat{A})$ is real and belongs to the spectrum of the operator $\hat{A}$ in the usual way.

Furthermore, $\sigma(V)$ is a compact Hausdorff space when it is equipped with the weak-$*$ topology, which is the weakest topology such that, for all $\hat{A} \in V$, the map $\hat{A} : \sigma(V) \to \mathbb{C}$ defined by

$$\hat{A}(\kappa) := \kappa(\hat{A}), \quad (2.2)$$

is continuous. The quantity $\hat{A}$ defined in Eq. (2.2) is known as the Gelfand transform of $\hat{A}$, and the spectral theorem for commutative von Neumann algebras asserts that the map $\hat{A} \mapsto \hat{A}$ is an isomorphism of $V$ with the algebra $C(\sigma(V))$ of complex-valued, continuous functions on $\sigma(V)$.

**Definition 2.3** The spectral presheaf over $\mathcal{V}$ is the contravariant functor $\Sigma : \mathcal{V} \to \text{Set}$ defined as follows:

---

In particular, Kochen and Specker in their original paper [3] formulate their theorem in terms of partial algebras which have a similar category-theoretic structure. Some recent work on the ‘modal interpretation’ focuses on certain ‘beable’ subalgebras of operators as those on which valuations can be constructed [4, 5].
• On objects: $\Sigma(V) := \sigma(V)$, where $\sigma(V)$ is the spectrum of the commutative von Neumann algebra $V$, i.e. the set of all multiplicative linear functionals $\kappa : V \to \mathbb{C}$.

• On morphisms: If $i_{V_2 V_1} : V_2 \to V_1$, so that $V_2 \subseteq V_1$, then $\Sigma(i_{V_2 V_1}) : \sigma(V_1) \to \sigma(V_2)$ is defined by $\Sigma(i_{V_2 V_1})(\kappa) := \kappa|_{V_2}$, i.e. this is the restriction of the functionals $\kappa : V_1 \to \mathbb{C}$ to $V_2$.

As discussed in [1] for the base category $\mathcal{O}$, the Kochen-Specker theorem may be written in terms of the spectral presheaf. If it existed, a global element of $\Sigma$ over $V$ would assign a multiplicative linear functional $\kappa : V \to \mathbb{C}$ to each commutative von Neumann algebra $V$ in $\mathcal{V}$ in such a way that these functionals match up as they are mapped down the presheaf. To be precise, the functional $\kappa$ on $V$ would be obtained as the restriction to $V$ of the functional $\kappa_1 : V_1 \to \mathbb{C}$ for any $V_1 \supseteq V$.

Furthermore, when restricted to the self-adjoint elements of $V$, a multiplicative linear functional $\kappa$ satisfies all the conditions of a valuation, namely:

1. the (real) value $\kappa(\hat{A})$ of $\hat{A}$ must belong to the spectrum of $\hat{A}$;

2. the functional composition principle $(\text{FUNC})$

$$\kappa(\hat{B}) = f(\kappa(\hat{A}))$$

holds for any self-adjoint operators $\hat{A}, \hat{B} \in V$ such that $\hat{B} = f(\hat{A})$.

The Kochen-Specker theorem, which states that no such valuations exist on all operators on a Hilbert space of dimension greater than two, can therefore be expressed as the statement that the presheaf $\Sigma$ over $\mathcal{V}$ has no global elements. The matching condition outlined above therefore cannot be satisfied over the whole of $\mathcal{V}$.

It is worth noting that a spectral presheaf may be associated with any (non-commutative) von Neumann algebra $\mathcal{N}$ by first considering the poset $\mathcal{A}(\mathcal{N})$ of all of its commutative sub-algebras as a category, and then constructing the functor $\Sigma : \mathcal{A} \to \text{Set}$ in the above manner. Similar comments apply to the other constructions introduced in the rest of this section.

2. The State Presheaf $S$ A state $\rho$ on a $C^*$-algebra $\mathcal{C}$ with unit 1 is a functional $\rho : \mathcal{C} \to \mathbb{C}$ that is
1. linear

2. positive; i.e. \( \rho(AA^*) \geq 0 \) for all \( A \in \mathcal{C} \)

3. normalised; so that \( \rho(1) = 1 \)

(see e.g. [3] p. 255). The space \( S \) of all states on some \( \mathcal{C}^* \)-algebra \( \mathcal{C} \) of operators is a convex set whose extreme points are the pure states. If \( \mathcal{C} \) is commutative, a state \( \rho \) is pure if and only if it is a multiplicative functional, i.e., \( \rho(AB) = \rho(A)\rho(B) \) for all \( A, B \in \mathcal{C} \). The set of pure states is therefore the spectrum of \( \mathcal{C} \); in particular, the real number \( \rho(A) \) will belong to the spectrum of \( \hat{A} \) for all self-adjoint operators \( \hat{A} \in \mathcal{C} \).

We now define the state presheaf.

**Definition 2.4** The state presheaf \( \mathbf{S} \) over \( \mathcal{V} \) is the contravariant functor \( \mathbf{S} : \mathcal{V} \to \text{Set} \) defined as follows:

- On objects: \( \mathbf{S}(V) \) is the space of states of the commutative von Neumann algebra \( V \).

- On morphisms: If \( i : V_2 \to V_1 \), so that \( V_2 \subseteq V_1 \), then \( \mathbf{S}(i) : \mathbf{S}(V_1) \to \mathbf{S}(V_2) \) is the restriction of the state functionals in \( \mathbf{S}(V_1) \) to \( V_2 \).

A global element of this presheaf is an assignment of a state to each commutative von Neumann subalgebra that is consistent in the sense that the state on any subalgebra \( V_1 \) may be obtained by restriction from any larger subalgebra, i.e. if \( V_1 \subseteq V_2 \) and \( V_1 \subseteq V_3 \), then the states \( \rho_2 \) on \( V_2 \) and \( \rho_3 \) on \( V_3 \) must agree on their common subalgebra, so that

\[
\rho_2(\hat{A}) = \rho_3(\hat{A})
\]

for all \( \hat{A} \in V_1 \).

One way to achieve this is to take a state \( \rho_{\mathcal{H}} \) on the (non-commutative) von Neumann algebra \( B(\mathcal{H}) \)—for example, given by a density matrix—and assign to each commutative subalgebra \( V \) of \( \mathcal{H} \) the state \( \rho_{\mathcal{H}|V} \) obtained by the restriction of \( \rho_{\mathcal{H}} \) to \( V \). However, there may be other global elements of \( \mathbf{S} \) which are not obtainable in this way.

The Kochen-Specker theorem tells us that the consistency condition above cannot be satisfied for an assignment of a pure state to each commutative subalgebra in \( \mathcal{V} \), as this would also be a global element of \( \Sigma \), and hence would correspond to a global valuation.
3 Sieve-Valued Generalised Valuations

In Section 2, we described the prohibition on global assignments of real-number values to quantum-theoretic quantities (the Kochen-Specker theorem), in terms of the state and spectral presheaves on $\mathcal{V}$. In this Section, we will describe some possible generalised valuations which are not excluded by the Kochen-Specker theorem.

These constructions will have certain properties which strongly suggest that they are appropriate generalisations of the idea of a valuation—in particular they satisfy a functional composition principle analogous to Eq. (2.3).

Sieve-valued valuations with these properties were introduced in \cite{1} using the base categories $\mathcal{O}$ and $\mathcal{W}$. These were motivated by the observation that partial, real-number-valued valuations (i.e., defined on only some subset of quantities) give rise to such valuations, and it was shown that quantum states could be used to define such valuations. In \cite{2}, these valuations were given more general motivations; in particular, classical physical analogues of the quantum-theoretic valuations were given.

This Section extends the discussions in \cite{1, 2}. First, we adapt to $\mathcal{V}$ the definitions, results and discussion of sieve-valued valuations. We will then look at other possible types of generalised valuation, namely those which are obtained by assigning to each quantity a subset of its spectrum. Some examples of these interval-valued valuations are exhibited, and related to the previous sieve-valued valuations.

3.1 The Coarse-Graining Presheaf $G$

We will follow \cite{1, 2} in assigning sieves primarily, not to quantities, but to propositions about the values of quantities. In \cite{1, 2}, sieves were assigned to propositions saying that the value of a quantity $\hat{A}$ lies in a Borel set $\Delta \subset \sigma(\hat{A})$, or more precisely, to the mathematical representative of the proposition, a projector $\hat{E}[A \in \Delta]$ in the spectral algebra $W_{\hat{A}}$ of $\hat{A}$.

The coarse-graining presheaf was defined over $\mathcal{O}$ (\cite{1}, Defn. 4.3) to show the behaviour of these propositions as they are mapped between the different stages of the presheaf. Thus the coarse-graining presheaf over $\mathcal{O}$ is the contravariant functor $G : \mathcal{O} \to \text{Set}$ defined as follows:

- **On objects in $\mathcal{O}$**: $G(\hat{A}) := W_{\hat{A}}$, where $W_{\hat{A}}$ is the spectral algebra of $\hat{A}$;
• On morphisms in \( \mathcal{O} \): If \( f_\mathcal{O} : \hat{B} \rightarrow \hat{A} \) (i.e., \( \hat{B} = f(\hat{A}) \)), then \( G(f_\mathcal{O}) : W_\hat{A} \rightarrow W_\hat{B} \) is defined as

\[
G(f_\mathcal{O})(\hat{E}[A \in \Delta]) := \hat{E}[f(A) \in f(\Delta)].
\] (3.1)

Note that the action of this presheaf coarsens propositions (and their associated projectors) since the function \( f \) will generally not be injective and so \( \hat{E}[f(A) \in f(\Delta)] \geq \hat{E}[A \in \Delta] \).

There are some subtleties arising from the fact that for \( \Delta \) a Borel subset of \( \sigma(\hat{A}) \), \( f(\Delta) \) need not be Borel. These are resolved in [1], theorem (4.1), by using the fact that if \( \hat{A} \) has a purely discrete spectrum (so that, in particular, \( f(\Delta) \) is Borel) then

\[
\hat{E}[f(A) \in f(\Delta)] = \inf\{\hat{Q} \in W_{f(A)} \subseteq W_A \mid \hat{E}[A \in \Delta] \leq \hat{Q}\}
\] (3.2)

where the infimum of projectors is taken in the (complete) lattice structure of all projectors on \( \mathcal{H} \). For a general self-adjoint operator \( \hat{A} \) we used this in [1] to define the coarse-graining operation; in other words, the projection operator denoted by \( \hat{E}[f(A) \in f(\Delta)] \) is defined using the right hand side of Eq. (3.2).

This infimum construction is used again in [1], Section 5.3, to define a corresponding coarse-graining presheaf over \( \mathcal{W} \), and our construction of \( G \) over \( \mathcal{V} \) is similar to this. Specifically, we define:

**Definition 3.1** The coarse-graining presheaf over \( \mathcal{V} \) is the contravariant functor \( G : \mathcal{V} \rightarrow \text{Set} \) defined as follows:

• On objects: \( G(V) \) is the lattice \( \mathcal{L}(V) \) of projection operators in \( V \).

• On morphisms: if \( i_{V_2V_1} : V_2 \rightarrow V_1 \) then \( G(i_{V_2V_1}) : \mathcal{L}(V_1) \rightarrow \mathcal{L}(V_2) \) is the coarse-graining operation defined on \( \hat{P} \in \mathcal{L}(V_1) \) by

\[
G(i_{V_2V_1})(\hat{P}) := \inf\{\hat{Q} \in \mathcal{L}(V_2) \mid \hat{P} \leq i_{V_2V_1}(\hat{Q})\}
\] (3.3)

where the infimum exists because \( \mathcal{L}(V_2) \) is complete.

The coarse-graining presheaf will play a central role in the definition of various types of generalised valuation. To set the scene, we will now discuss how propositions about the quantum system behave when coarse-grained to different stages in the base category \( \mathcal{V} \). As we will now see, this is more
subtle than the analogous process using the base category $O$ or $W$ (discussed in [1, 2]).

In $O$, a proposition about a quantum system at some stage $\hat{A} \in O$ is a statement “$A \in \Delta$” that the value of the quantity $A$ lies in some Borel subset $\Delta$ of the spectrum $\sigma(\hat{A})$ of the self-adjoint operator $\hat{A}$ that represents $A$. This proposition is associated with the stage $\hat{A}$ in $O$, and is represented by the projector $\hat{E}[A \in \Delta] \in W_A$, where $W_A$ is the spectral algebra of $\hat{A}$. For any $f_O : \hat{B} \to \hat{A}$, so that $\hat{B} = f(\hat{A})$, the coarse-graining operation acts on the projector as follows:

$$G(f_O)(\hat{E}[A \in \Delta]) = \hat{E}[f(A) \in f(\Delta)] = \hat{E}[B \in f(\Delta)]$$

(3.4)

where $\hat{E}[B \in f(\Delta)]$ is understood in the sense explained above.

This idea of coarse-graining means that the proposition “$A \in \Delta$” at stage $\hat{A}$ in $O$ ‘changes’ in two ways under coarse-graining. First, the associated projector may change—we can have $\hat{E}[f(A) \in f(\Delta)] > \hat{E}[A \in \Delta]$. The second change—which always occurs—is that the stage of the proposition changes: after coarse-graining, we have a proposition at stage $f(\hat{A})$ in $O$, so that the representing projector $\hat{E}[f(A) \in f(\Delta)]$ is thought of as belonging to $W_{f(A)}$, even if, in fact, $\hat{E}[f(A) \in f(\Delta)] = \hat{E}[A \in \Delta]$. In short: there is no difficulty in interpreting a proposition (or projector) at a stage as associated with that stage’s quantity.

Similar remarks apply to $W$. The main difference from $O$ is that for $W$, a stage corresponds to an equivalence class of quantities or operators (viz. under the relation of being functions of each other), not a single quantity or operator. This just means that we interpret a proposition “$A \in \Delta$”, or projector $\hat{E}[A \in \Delta]$, as associated with the entire stage, i.e., the Boolean algebra $W_A$, not with the specific quantity $A$ or the specific operator $\hat{A}$. But the main point remains the same: that with either $O$ or $W$, there is no difficulty in interpreting a proposition or projector at a stage as associated with that stage—be it a quantity/operator; or an equivalence class, or common spectral algebra, of such.

However, in $V$, the role of propositions such as “$A \in \Delta$” and the corresponding projectors, $\hat{E}[A \in \Delta]$, is not so clear. For any stage $V$ with $\hat{A} \in V$, the projector $\hat{E}[A \in \Delta]$ will belong to the spectral algebra of many different operators in $V$. Indeed, it will generally also belong to the spectral algebra of many operators not in $V$, so we may write the projector as $\hat{E}[B \in \Delta_B]$ for a large number of operators $\hat{B}$ with corresponding sets $\Delta_B \subset \sigma(\hat{B})$ and with $\hat{B} \notin V$. 

9
So intuition pulls in two directions. On the one hand, similarly to \( W \) above, the fact that the objects of the base category \( V \) are not operators, but von Neumann algebras, prompts us to interpret a proposition \( "A \in \Delta" \) as associated with the entire stage, i.e., with the algebra \( V \), rather than with the specific physical quantity \( A \) or the corresponding specific operator \( \hat{A} \). But on the other hand, similarly to \( O \) above, operators are elements of stages, so that when \( \hat{A} \) does belong to \( V \) it seems natural to think of a proposition \( "A \in \Delta" \) at a stage \( V \) in terms of the operator \( \hat{A} \).

We favour the former option, since the latter option faces difficulties when we consider coarse-graining to a stage \( V_2 \subset V_1 \) which may not contain the operator \( \hat{A} \). To spell these out, let us start by noting that to understand how the proposition \( "A \in \Delta" \) at stage \( V_1 \) (or, more precisely, the projector \( \hat{E}[\hat{A} \in \Delta] \in \mathcal{L}(V_1) \)) coarse-grains to some stage \( V_2 \subset V_1 \), according to Definition (3.1)

\[
G(\nu_{V_2|V_1})(\hat{E}[A \in \Delta]) = \inf \left\{ \hat{Q} \in \mathcal{L}(V_2) \mid \hat{E}[A \in \Delta] \leq \nu_{V_2|V_1}(\hat{Q}) \right\},
\]

we need in general to consider three possibilities, according to whether or not \( \hat{A} \) and the projector \( \hat{E}[A \in \Delta] \) are in \( V_2 \):

1. \( \hat{A} \in V_2 \). In this case, \( \hat{E}[A \in \Delta] \in \mathcal{L}(V_2) \subset V_2 \), and so the projector coarse-grains to itself: \( G(\nu_{V_2|V_1})(\hat{E}[A \in \Delta]) = \hat{E}[A \in \Delta] \). And since \( \hat{A} \in V_2 \), it is natural to assign the same interpretation—as a proposition about the value of \( \hat{A} \)—to the coarse-grained projector.

2. \( \hat{A} \notin V_2 \) but \( \hat{E}[A \in \Delta] \in V_2 \). In this case, the projector \( \hat{E}[A \in \Delta] \) still coarse-grains to itself, mathematically speaking. However, it is not clear how the projector at stage \( V_2 \) could be interpreted in terms of the value of \( \hat{A} \), since \( \hat{A} \) is not present at that stage.

3. \( \hat{A} \notin V_2 \) and \( \hat{E}[A \in \Delta] \notin V_2 \). In this case, the coarse-grained projector is not the same as the original one, and so the proposition associated with it will no doubt be different. It is again unclear how one could interpret the coarse-grained projector in terms of \( \hat{A} \): indeed, there is in general no clear choice as to which operator in \( V_2 \) is to be the topic of the coarse-grained proposition.

In the light of these difficulties, we will instead adopt the first option above: we interpret a projector \( \hat{P} \in \mathcal{L}(V_1) \) as a proposition about the entire stage \( V_1 \). Formally, we can make this precise in terms of the spectrum of the algebra \( V_1 \). That is to say, we note that:

\[
\]
• Any projector \( \hat{P} \in \mathcal{L}(V_1) \) corresponds not only to a subset of the spectrum of individual operators \( \hat{A} \in V \) (where \( \hat{P} \in W_A \) so \( \hat{P} = \hat{E}[A \in \Delta] \) for some \( \Delta \subset \sigma(\hat{A}) \)), but also to a subset of the spectrum of the whole algebra \( V_1 \), namely, those multiplicative linear functionals \( \kappa : V_1 \to \mathbb{C} \) such that \( \kappa(\hat{P}) = 1 \).

• Coarse-graining respects this interpretation in the sense that if we interpret \( \hat{P} \in \mathcal{L}(V_1) \) as a proposition about the spectrum of the algebra \( V_1 \), then the coarse-graining of \( \hat{P} \) to some \( V_2 \subset V_1 \), given by \( \inf\{ \hat{Q} \in \mathcal{L}(V_2) \mid \hat{P} \leq i_{V_2 V_1}(\hat{Q}) \} \) is a member of \( \mathcal{L}(V_2) \), and so can be interpreted as a proposition about the spectrum of the algebra \( V_2 \).

This treatment of propositions as concerning the spectra of commutative von Neumann algebras, rather than individual operators, amounts to the semantic identification of all propositions in the algebra corresponding to the same mathematical projector. Thus when we speak of a proposition “\( A \in \Delta \)” at some stage \( V \), with \( \hat{A} \in V \), we really mean the corresponding proposition about the spectrum of the whole algebra \( V \) defined using the projector \( \hat{E}[A \in \Delta] \). In terms of operators, the proposition “\( A \in \Delta \)” is augmented by incorporating in it all corresponding propositions “\( B \in \Delta_B \)” about other operators \( \hat{B} \in V \) such that the projector \( \hat{E}[A \in \Delta] \) belongs to the spectral algebra of \( \hat{B} \), and \( \hat{E}[A \in \Delta] = \hat{E}[B \in \Delta_B] \).

**Definition 3.2** The augmented proposition at stage \( V \) in \( \mathcal{V} \) associated to the projector \( \hat{P} \in V \) is the collection of all propositions of the form “\( A \in \Delta \)” where \( \hat{A} \in V \) and the Borel set \( \Delta \subset \mathbb{R} \) are such that \( \hat{E}[A \in \Delta] = \hat{P} \).

These augmented propositions in \( \mathcal{V} \) then coarse-grain in an analogous way to standard propositions in \( \mathcal{O} \): the augmented proposition “\( A \in \Delta \)” at stage \( V_1 \) is coarse-grained to “\( f(A) \in f(\Delta) \)”, and the result is an augmented proposition at the lower stage \( V_2 \).

In [1] Section 4.2.3, it was noted that the coarse-graining presheaf over \( \mathcal{O} \) was essentially the same as the presheaf \( B\Sigma \) over \( \mathcal{O} \), which assigns to each \( \hat{A} \) in \( \mathcal{O} \) the Borel subsets of the spectrum of \( \hat{A} \). The presheaf \( B\Sigma \) on \( \mathcal{O} \) was essentially the Borel power object of \( \Sigma \), containing those subobjects of \( \Sigma \) which are formed of Borel sets of spectral values, with a projector \( \hat{E}[A \in \Delta] \in G(\hat{A}) \) corresponding to the Borel subset \( \Delta \subset \Sigma(\hat{A}) \). This connection between projectors and subsets of spectra carries over to the algebra case.
A projection operator $\hat{P} \in V$ corresponds to a subset of the spectrum of $V$, namely the set of multiplicative linear functionals $\kappa$ on $V$ such that $\kappa(\hat{P}) = 1$. Bearing in mind that, for each $\hat{A}$ in $B(\mathcal{H})$, the function $\hat{A} : \sigma(V) \mapsto \mathbb{C}$ given by the Gelfand transform of $\hat{A}$, $\hat{A}(\kappa) := \kappa(\hat{A})$, is continuous, we see that the subset of the spectrum of $\sigma(V)$ that corresponds to $\hat{P}$ is closed in the compact Hausdorff topology of $\sigma(V)$.

In fact, we can say more than this since, by virtue of the spectral theorem for commutative $C^*$-algebras, the operator $\hat{P} \in V$ is represented by a function $\tilde{P} : \sigma(V) \rightarrow \mathbb{R}$. Since $\tilde{P}^2 = \tilde{P}$, we see that $\tilde{P}$ is necessarily the characteristic function, $\chi_P$ say, of some subset of $V$, namely the set of all multiplicative linear functionals $\kappa$ on $V$ such that $\kappa(\hat{P}) = 1$. However, by virtue of the spectral theorem, $\chi_P$ is in fact a continuous function from $\sigma(V)$ to $\{0, 1\} \subset \mathbb{R}$, and hence the subset concerned is both open and closed. Thus the subset of $\sigma(V)$ corresponding to a projection operator $\hat{P} \in V$ is a clopen subset in the spectral topology. Conversely, of course, each clopen subset of $\sigma(V)$ corresponds to a projection operator $\hat{P}$ whose representative function $\tilde{P}$ on $\sigma(V)$ is the characteristic function of the subset.

So in analogy with $B\Sigma$ on $\mathcal{O}$, we may define a similar presheaf on $\mathcal{V}$, which we will denote $\text{Clo}\Sigma$:

- **On objects**: $\text{Clo}\Sigma(V)$ is defined to be the set of clopen subsets of the spectrum $\sigma(V)$ of the algebra $V$; each such clopen set is the set of multiplicative linear functionals $\kappa$ such that $\kappa(\hat{P}) = 1$ for some projector $\hat{P} \in V$.

- **On morphisms**: for $V_2 \subset V_1$, we define

$$\text{Clo}\Sigma(i_{V_2V_1}) \left( \{ \kappa \in \sigma(V_1) \mid \kappa(\hat{P}) = 1 \} \right) = \{ \chi \in \sigma(V_2) \mid \chi(G(i_{V_2V_1})(\hat{P})) = 1 \}$$

(3.6)

There is an isomorphism between $G$ and $\text{Clo}\Sigma$, and so we can think of $G$ on $\mathcal{V}$ as being the ‘clopen’ power object of $\Sigma$ on $\mathcal{V}$.

### 3.2 Sieve-Valued Generalised Valuations

In view of the discussion of propositions in the previous subsection, our definition of a sieve-valued generalised valuation for the base category $\mathcal{V}$ will define the valuations on projectors in the explicit context of an algebra $V$. That is to say, the truth-value associated with a projector $\hat{P}$ depends on the
context of a particular algebra $V$ containing $\hat{P}$. As in any topos of presheaves (cf. [1], Appendix), the subobject classifier $\Omega$ in the topos $\operatorname{Set}^{\text{op}}$ is a presheaf of sieves. Since $\mathcal{V}$ is a poset, sieves may be identified with lower sets in the poset. We define $\Omega$ as follows:

- On objects: $\Omega(V)$ is the set of sieves in $\mathcal{V}$ on $V$;

  We recall that $\Omega(V)$ has (i) a minimal element, the empty sieve, $0_V = \emptyset$, and (ii) a maximal element, the principal sieve, $\text{true}_V = \downarrow_V := \{V' \mid V' \subseteq V\}$.

- On morphisms: $\Omega(i_{V_2V_1}) : \Omega(V_1) \to \Omega(V_2)$ is the pull-back of the sieves in $\Omega(V_1)$ along $i_{V_2V_1}$ defined by:

$$
\Omega(i_{V_2V_1})(S) = i_{V_2V_1}^*(S) := \{i_{V_3V_2} : V_3 \to V_2 \mid i_{V_3V_2} \circ i_{V_2V_1} \in S\} \quad (3.7)
$$

for all sieves $S \in \Omega(V_1)$.

Then we define:

**Definition 3.3** A sieve-valued generalised valuation on the category $\mathcal{V}$ in a quantum theory is a collection of maps $\nu_V : \mathcal{L}(V) \to \Omega(V)$, one for each ‘stage of truth’ $V$ in the category $\mathcal{V}$, with the following properties:

(i) **Functional composition:**

For any $\hat{P} \in \mathcal{L}(V)$ and any $V' \subseteq V$ so that $i_{V'V} : V' \to V$

$$
\nu_{V'}(G(i_{V'V}(\hat{P}))) = i_{V'V}^*(\nu_V(\hat{P})). \quad (3.9)
$$

(ii) **Null proposition condition:**

$$
\nu_V(\hat{0}) = 0_V \quad (3.10)
$$

(iii) **Monotonicity.**

If $\hat{P}, \hat{Q} \in \mathcal{L}(V)$ with $\hat{P} \leq \hat{Q}$, then $\nu_V(\hat{P}) \leq \nu_V(\hat{Q})$.

$$
\nu(\text{iv}) \; \text{Exclusivity.} \quad (3.11)
$$

We may wish to supplement this list with:

$\gamma$ (iv) **Exclusivity.**

13
If \( \hat{P}, \hat{Q} \in \mathcal{L}(V) \) with \( \hat{P} \hat{Q} = 0 \) and \( \nu_V(\hat{P}) = \text{true}_V \), then \( \nu_V(\hat{Q}) < \text{true}_V \) \hspace{1cm} (3.12)

and (v) Unit proposition condition:

\[
\nu_V(\hat{1}) = \text{true}_V. \tag{3.13}
\]

Note that in writing Eq. (3.9), we have employed Definition 3.1 to specify the coarse-graining operation in terms of an infimum of projectors, as motivated by Theorem 4.1 of [1].

The topos interpretation of these generalised valuations remains as discussed in Section 4.2 of [1] and Section 4 of [2]. Adapting the results and discussion to the category \( \mathcal{V} \), we have in particular the result that because of the FUNC condition, Eq. (3.9), the maps \( N^\nu_V : \mathcal{L}(V) \to \Omega(V) \) defined at each stage \( V \) by:

\[
N^\nu_V(\hat{P}) = \nu_V(\hat{P}) \tag{3.14}
\]

define a natural transformation \( N^\nu \) from \( G \) to \( \Omega \). Since \( \Omega \) is the subobject-classifier of the topos of presheaves, \( \text{Set}^{\mathcal{V}^{\text{op}}} \), these natural transformations are in one-to-one correspondence with subobjects of \( G \); so that each generalised valuation defines a subobject of \( G \). We will pursue this topic in more detail in Section 4.4.3.

3.3 Sieve-Valued Valuations Associated with Quantum States

We recall (for example, [1], Definition 4.5) that each quantum state \( \rho \) defines a sieve-valued generalised valuation on \( \mathcal{O} \) or \( \mathcal{W} \), in a natural way. For example, on \( \mathcal{O} \), the generalised valuation was defined as

\[
\nu^\rho(A \in \Delta) := \{ f_O : \hat{B} \to \hat{A} \mid \text{Prob}(B \in f(\Delta); \rho) = 1 \}
= \{ f_O : \hat{B} \to \hat{A} \mid \text{tr}(\rho \hat{E}[B \in f(\Delta)]) = 1 \} \tag{3.15}
\]

Thus the generalised valuation associates to the proposition all arrows in \( \mathcal{O} \) along which the projector corresponding to the proposition coarse-grains to a projector which is ‘true’ in the usual sense of having a Born-rule probability equal to 1. This construction is easily seen to be a sieve, and satisfies conditions analogous to Eqs. (3.9–3.13) for a generalised valuation on \( \mathcal{O} \) ([1], Section 4.4).
We also recall that there is a one-parameter family of extensions of these valuations, defined by relaxing the condition that the proposition coarse-grains along arrows in the sieve to a ‘totally true’ projector. That is to say, we can define the sieve

\[ \nu^{\rho,r}(A \in \Delta) := \{ f_\mathcal{O} : \hat{B} \to \hat{A} \mid \text{Prob}(B \in f(\Delta) ; \rho) \geq r \} \]

\[ = \{ f_\mathcal{O} : \hat{B} \to \hat{A} \mid \text{tr}(\rho \hat{E}[B \in f(\Delta)]) \geq r \} \]

(3.16)

where the proposition “\( A \in \Delta \)” is only required to coarse-grain to a projector that is true with some probability greater than \( r \), where \( 0.5 \leq r \leq 1 \).

Furthermore, if one drops the exclusivity condition, one can allow probabilities less than 0.5, i.e. \( 0 < r < 0.5 \).

We now introduce the same kind of valuation using \( \mathcal{V} \) as the base category.

As was discussed in Section 3.1 in relation to \( \mathcal{G} \), when using the base category \( \mathcal{V} \) it is more natural to interpret a projector \( \hat{P} \in \mathcal{L}(\mathcal{V}) \) as a proposition about the spectrum of the commutative subalgebra \( \mathcal{V} \), rather than about the value of just one operator. Such an augmented proposition at a stage \( \mathcal{V} \) in \( \mathcal{V} \) will correspond to a projector \( \hat{P} \in \mathcal{L}(\mathcal{V}) \), and can be thought of as the family of propositions “\( A \in \Delta \)” for all \( \hat{A} \in \mathcal{V} \) that have \( \hat{P} \) as a member of their spectral algebra with \( \hat{E}[A \in \Delta] = \hat{P} \).

So we define a sieve-valued generalised valuation associated with a quantum state \( \rho \) as follows:

**Definition 3.4** The sieve-valued valuation \( \nu^{\rho}_{\mathcal{V}_1} \) of a projector \( \hat{P} \in \mathcal{V}_1 \) associated with a quantum state \( \rho \) is defined by:

\[ \nu^{\rho}_{\mathcal{V}_1}(\hat{P}) := \{ i_{\mathcal{V}_2 \mathcal{V}_1} : \mathcal{V}_2 \to \mathcal{V}_1 \mid \rho [\mathcal{G}(i_{\mathcal{V}_2 \mathcal{V}_1})(\hat{P})] = 1 \} \]

(3.17)

This assigns as the truth-value at stage \( \mathcal{V}_1 \) of a projector \( \hat{P} \in \mathcal{V}_1 \), a sieve on \( \mathcal{V}_1 \) containing (morphisms to \( \mathcal{V}_1 \) from) all stages \( \mathcal{V}_2 \) at which \( \hat{P} \) is coarse-grained to a projector which is ‘totally true’ in the usual sense of having Born-rule probability 1.

One readily verifies that Eq. (3.17) defines a generalised valuation in the sense of Definition 3.3. The verification is the same, *mutatis mutandis*, as for generalised valuations on \( \mathcal{O} \), given in Section 4.4 of [1]. As an example, we take the functional composition condition. Again, this requires that the sieves pull back in the appropriate manner; if \( \mathcal{V}_2 \subseteq \mathcal{V}_1 \) and hence \( i_{\mathcal{V}_2 \mathcal{V}_1} : \mathcal{V}_2 \to \mathcal{V}_1 \),
then:

\[ i_{V_2 V_1}^\rho (\nu_{V_1}^c (\hat{P})) := \{ i_{V_3 V_2} : V_3 \to V_2 \mid i_{V_3 V_1} \circ i_{V_3 V_2} \in \nu_{V_1}^c (\hat{P}) \} \quad (3.18) \]

\[ = \{ i_{V_3 V_2} : V_3 \to V_2 \mid \rho [G(i_{V_2 V_1} \circ i_{V_3 V_2})(\hat{P})] = 1 \} \quad (3.19) \]

whereas

\[ \nu_{V_2}^\rho (G(i_{V_2 V_1})(\hat{P})) := \{ i_{V_3 V_2} : V_3 \to V_2 \mid \rho [G(i_{V_2 V_1})(G(i_{V_2 V_1})(\hat{P}))] = 1 \} \quad (3.20) \]

and hence \( FUNC \) is satisfied since \( G(i_{V_2 V_1} \circ i_{V_3 V_2})(\hat{P}) = G(i_{V_2 V_1})(G(i_{V_2 V_1})(\hat{P})) \).

Again, we can obtain a one-parameter family of such valuations by introducing a probability \( r \):

\[ \nu_{V_1}^{\rho r} (\hat{P}) := \{ i_{V_2 V_1} : V_2 \to V_1 \mid \rho [G(i_{V_2 V_1})(\hat{P})] \geq r \} \quad (3.21) \]

### 4 Interval-Valued Generalised Valuations

#### 4.1 Introducing Interval-Valued Valuations

The sieve-valued generalised valuations on \( V \) discussed in Section 3, and their analogues on \( O \) and \( W \) (discussed in \[1, 2\]) are one way of assigning a generalised truth value to propositions in a way that is not prevented by the Kochen-Specker theorem. We are now going to investigate another possibility—of assigning sets of real numbers to operators—and relate it to our generalised valuations. An algebra \( V \) in \( V \) will be assigned a subset of its spectrum, \( i.e. \) a set of multiplicative linear functionals on \( V \) which corresponds to a subset of the spectrum of each operator in the algebra.

We will call such assignments ‘interval valuations’, as the primary motivation for these assignments is the wish to assign some interval of real numbers to each operator. Note that, in the latter context, ‘interval’ means just some subset of \( \mathbb{R} \), that is to say, an interval in our sense need not be a connected subset.

Despite the marked difference between interval-valued and sieve-valued valuations —projectors or propositions \emph{versus} algebras as arguments, and sieves \emph{versus} sets of real functionals as values—it turns out that these two kinds of valuations are closely related.
4.2 Subobjects of $\Sigma$

We now consider assigning to each algebra $V$ in $\mathcal{V}$ a clopen subset $I(V) \subseteq \sigma(V)$. This set $I(V)$ of multiplicative linear functionals $\kappa$ on $V$ leads to an assignment to each self-adjoint operator $\hat{A} \in V$ of a subset of the spectrum of the operator, $\Delta_A = \{ \kappa(\hat{A}) \mid \kappa \in I(V) \} \subseteq \sigma(\hat{A})$, in such a way that the appropriate relationships between these subsets are obeyed, so that if $\hat{B} = f(\hat{A})$, we have $\Delta_B = f(\Delta_A)$. For we note that $\Delta_A$ is equal to $\tilde{A}[I(V)]$, where the Gelfand transform $\tilde{A} : \sigma(V) \to \mathbb{R}$ is defined in Eq. (2.3). However, $I(V)$ is a closed subset of the compact Hausdorff space $\sigma(V)$, and hence is itself compact. Then, since $\tilde{A} : \sigma(V) \to \mathbb{R}$ is continuous, it follows that $\tilde{A}[I(V)]$ is also compact; thus $\Delta_A$ is a compact subset of $\mathbb{R}$.

On the face of it, the fact that $\Delta_A$ is compact might appear problematical for functions $f : \sigma(\hat{A}) \to \mathbb{R}$ that are Borel but not continuous (since the image of a compact set by a Borel function need not itself be compact). In effect, the problem is that $f \circ \tilde{A} : \sigma(V) \to \mathbb{R}$ may not be continuous, even though it is supposed to represent the operator $\tilde{B} = f(\hat{A})$. However, a more careful study of the spectral theorem for a commutative von Neumann algebra shows that the Borel function $f \circ \tilde{A}$ can be replaced by a unique continuous function (i.e., $\tilde{B}$) without changing anything of significance in the algebraic structure of $\tilde{A}[I(V)]$ is to be understood as $\Delta_B = f(\Delta_A)$ where necessary.

One of course expects to require such an interval-valued assignment, $I$, to obey some version of $FUNC$ along morphisms in the category $\mathcal{V}$. The most obvious version is, for $V_2 \subset V_1$:

$$ I(V_2) = I(V_1)|_{V_2} \quad (4.1) $$

so that the functionals in $I(V_2)$ are just the restriction to $V_2$ of those in $I(V_1)$.

But from the perspective of the theory of presheaves, it is natural to take such assignments $I$ as given by subobjects of $\Sigma$. These clearly exist—for example there is the trivial subobject assigning to each algebra the whole of its spectrum. One can think of the Kochen-Specker theorem as restricting the 'smallness' of the subobjects: we cannot take a subobject that consists of a singleton set at each stage, since that would be a global element. If $I$ is a subobject of $\Sigma$, it will obey (by the definition of 'subobject') a weaker...
version of $FUNC$: viz.,
\[ I(i_{V_2V_1})(I(V_1)) := I(V_1)|_{V_2} \subseteq I(V_2) \] (4.2)

**Example 1:** The ‘true’ subobject of $\Sigma$ arising from a quantum state

One subset of the spectrum of an operator $\hat{A}$ which arises naturally from a quantum state $\rho$ is the set of values which can occur in a measurement of $\hat{A}$ when the system is in the state $\rho$. This set $\Delta_A$ is given in the following way.

For any pair of projectors $\hat{E}[A \in \Delta], \hat{E}[A \in \Delta'] \in W_A$, such that $\text{tr}(\rho \hat{E}[A \in \Delta]) = \text{tr}(\rho \hat{E}[A \in \Delta']) = 1$, there is a smaller projector $\hat{E}[A \in \Delta''] = \hat{E}[A \in \Delta] \hat{E}[A \in \Delta']$ (where $\Delta'' = \Delta \cap \Delta'$) such that $\text{tr}(\rho \hat{E}[A \in \Delta'']) = 1$, and so we may form a descending net of projectors whose infimum exists, and belongs to $W_A$, since $W_A$ is complete. Thus there is a smallest projector $\hat{E}_{\min}$ which is of the form $\hat{E}[A \in \Delta_A]$ for some subset $\Delta_A$ of the spectrum of $\hat{A}$. Furthermore, the net of projectors converges strongly (and therefore weakly) to $\hat{E}[A \in \Delta_A]$, and therefore, since—for fixed $\rho$—the map $B(H) \to \mathbb{C}$ given by $\hat{A} \to \text{tr}(\rho \hat{A})$, is weakly continuous, it follows that $\text{tr}(\rho \hat{E}[A \in \Delta_A]) = 1$. This operator $\hat{E}_{\min} = \hat{E}[A \in \Delta_A]$ is sometimes called the support of $\hat{A}$ in the state $\rho$.

For an algebra $V$, we can define the corresponding subset of its spectrum by taking those multiplicative linear functionals on $V$ which assign the value 1 to each ‘true projector’, i.e., those projectors in $T^\rho(V) := \{ \hat{P} \in V \mid \text{tr}(\rho \hat{P}) = 1 \} \subseteq \mathcal{L}(V)$. The connection to the above assignment to operators is clear; for if $\hat{A} \in V$, then $\Delta_A = \{ \kappa(\hat{A}) \mid \kappa(\hat{P}) = 1, \ \forall \hat{P} \in T^\rho(V) \}$.

So the corresponding ‘true subobject’ of $\Sigma$ is given by:
\[ \Gamma^\rho(V) = \{ \kappa \in \sigma(V) \mid \kappa(\hat{P}) = 1, \ \forall \hat{P} \in T^\rho(V) \}. \] (4.3)

Again, since the map $\hat{P} \to \text{tr}(\rho \hat{P})$ is weakly continuous, the infimum $\hat{Q} := \inf\{ \hat{P} \in T^\rho(V) \}$ is in $T^\rho(V)$. Since $\kappa(\hat{Q}) = 1$ implies $\kappa(\hat{P}) = 1$ for all $\hat{P} \in T^\rho(V)$, the above construction may be written as the clopen set
\[ \Gamma^\rho(V) := \{ \kappa \in \sigma(V) \mid \kappa(\hat{Q}) = 1 \} \] (4.4)
and so for non-trivial $\hat{Q}$ this will necessarily be a proper subset of $\sigma(V)$ (cf. the discussion at the end of Section 3.1 on the connection between projectors and subsets of spectra, in relation to Clo$\Sigma$).

The above construction describes a subobject of $\Sigma$ since if we have $V_2 \subseteq V$ then
\[ \Gamma^\rho(V_2) = \{ \kappa \in \sigma(V_2) \mid \kappa(\hat{P}) = 1 \ \forall \hat{P} \in T^\rho(V_2) \} \] (4.5)
and since $T^\rho(V_2) = \{ \hat{P} \in V_2 \mid \text{tr}(\rho \hat{P}) = 1 \} \subseteq T^\rho(V)$, we have that $\hat{Q}_2 \geq \hat{Q}$. Therefore $\{ \kappa \mid \kappa(\hat{Q}) = 1 \} \subseteq \{ \kappa \mid \kappa(\hat{Q}_2) = 1 \}$, and hence $I^\rho(V)|_{V_2} \subseteq I^\rho(V_2)$ as required for the subobject condition (4.2) to hold.

**Example 2: Subobjects of $\Sigma$ from sieve-valued valuations** Given an extra condition on a sieve-valued valuation $\nu$, the above construction of the ‘true subobject’ of $\Sigma$ can be adapted to use $\nu$ to define an interval-valuation $I^\nu$ via:

$$I^\nu(V) = \{ \kappa \in \sigma(V) \mid \kappa(\hat{P}) = 1, \quad \forall \hat{P} \in T^\nu(V) \} \quad \text{(4.6)}$$

where now we define

$$T^\nu(V) := \{ \hat{P} \in \mathcal{L}(V) \mid \nu(\hat{P}) = \text{true}_V \}. \quad \text{(4.7)}$$

We now look at the conditions under which this gives a subobject of $\Sigma$. We note first that Eq. (4.3) is not in general a proper subset of $\sigma(V)$. It will be empty unless the infimum $\hat{Q}$ of the set of projectors $T^\nu(V)$ is non-zero; for we can again write $I^\nu(V)$ in the form of the clopen set

$$I^\nu(V) = \{ \kappa \in \sigma(V) \mid \kappa(\hat{Q}) = 1 \} \quad \text{(4.8)}$$

which must be empty if $\hat{Q} = \hat{0}$, the zero projector.

The condition on $\nu$ for this construction to be a subobject is a matching condition on this infimum:

$$\text{For } V_1 \subset V \text{ we require that } \hat{Q}_1 \geq \hat{Q} \quad \text{(4.9)}$$

where $\hat{Q}$ and $\hat{Q}_1$ are the infima of the sets $T^\nu(V)$ and $T^\nu(V_1)$ respectively, defined as above. For, if this is not the case, there will be some $\kappa \in \sigma(V)$ such that $\kappa(\hat{Q}) = 1$ (and hence $\kappa \in I^\nu(V)$) but $\kappa(\hat{Q}_1) < 1$. Therefore $\kappa|_{V_1} \not\in I^\rho(V_1)$, and the subobject condition Eq. (4.2) will not be satisfied.

A sufficient condition for Eq. (4.9) to hold is that if $V_1 \subset V$ then $T^\nu(V_1) \subseteq T^\nu(V)$. This condition is satisfied for the valuation $\nu^\rho$ arising from a quantum state in the probability one case via Eq. (3.15), and the resulting construction is, of course, the same as the Example 1 above.

The condition also holds for valuations from a quantum state $\nu^{\rho,r}$ where a probability $r$ is introduced, as in Eq. (3.21). In that case, however, there will be many algebras $V \in \mathcal{V}$ where there is no non-trivial infimum to the set $T^\nu(V)$, and so the corresponding subobject of $\Sigma$ will be the empty set over much of $\mathcal{V}$. 

19
4.3 Global Elements of G

As was discussed at the end of Section 3.1, there is a natural interpretation of the coarse-graining presheaf \( G \) as a subobject of the power object of \( \Sigma \), i.e., a presheaf of subobjects of \( \Sigma \).

Given this interpretation of \( G \), it is natural to take interval-valued valuations as given by global elements of \( G \). A global element \( \gamma \) of \( G \) obeys, for \( V_2 \subset V_1 \):

\[
\gamma(V_2) = G(i_{V_2V_1})(\gamma(V_1)),
\]

which is a \( FUNC \) condition with an equality like Eq. (4.1) (as opposed to the subset version Eq. (4.2) required for subobjects of \( \Sigma \)).

Recalling that for any projector selected by \( \gamma \) at stage \( V_1 \), i.e. \( \gamma(V_1) = \hat{P} \in \mathcal{L}(V_1) \), the action of \( G \) is \( G(i_{V_2V_1}) : \hat{P} \mapsto \inf \{ \hat{Q} \in \mathcal{L}(V_2) \mid \hat{P} \leq i_{V_2V_1}(\hat{Q}) \} \), we see that any such global element \( \gamma \) defines an assignment \( I^\gamma \) to each algebra of a subset of its spectrum by:

\[
I^\gamma(V_1) := \{ \kappa \in \sigma(V_1) \mid \kappa(\gamma(V_1)) = 1 \}
\]

and, since \( \hat{P} \leq G(i_{V_2V_1})(\hat{P}) \), we see that \( \kappa(\hat{P}) = 1 \) implies \( \kappa(G(i_{V_2V_1})(\hat{P})) = 1 \), so that \( I^\gamma(V_1)|_{V_2} \subseteq I^\gamma(V_2) \), and hence this construction is a subobject of \( \Sigma \) as well as an interval-valued valuation satisfying the stronger version of \( FUNC \), Eq. (4.1).

In this way, an interval-valued valuation—assigning a subset of the spectrum at each stage—is given by every global element of \( G \).

As in Example 2 of the previous Subsection, certain sieve-valued valuations can be used to give global elements of \( G \). The natural way to define such a global element is by:

\[
\gamma^\nu(V_1) := \inf \{ \hat{P} \in \mathcal{L}(V_1) \mid \nu_{V_1}(\hat{P}) = \text{true}_{V_1} \}
\]

where again, as in Eq. (4.7), \( T^\nu(V_1) := \{ \hat{P} \in \mathcal{L}(V_1) \mid \nu_{V_1}(\hat{P}) = \text{true}_{V_1} \} \).

The matching condition for this to be a global element of \( G \) is stronger than for it to be a subobject of \( \Sigma \): we now require that for every \( V_2 \subset V_1 \),

\[
\inf \{ \hat{P} \in T^\nu(V_2) \} =: \hat{Q}_2 = G(i_{V_2V_1}) \left( \inf \{ \hat{P} \in T^\nu(V_1) \} \right) = G(i_{V_2V_1})(\hat{Q}_1).
\]

The case of a valuation arising from a quantum state for the probability one case—Example 1 in the previous Subsection—may be cast in this form.
For that case we have that if $V_2 \subset V_1$ then $T^\rho(V_2) = \{ \hat{P} \in V_2 \mid \text{tr}(\rho \hat{P}) = 1 \} \subseteq T^\rho(V_1)$, and so each $\hat{P}_2 \in V_2$ is given by $G(i_{V_2 V_1})(\hat{P}_1)$ for some $\hat{P}_1 \in V_1$, since in particular this is true when $\hat{P}_1, \hat{P}_2$ denote the same projector thought of as belonging to $V_1$ and $V_2$ respectively. Then since $\hat{P}_1 \leq \hat{P}_1'$ implies $G(i_{V_2 V_1})(\hat{P}_1) \leq G(i_{V_2 V_1})(\hat{P}_1')$, it follows that $\inf\{ \hat{P} \in T^\rho(V_2) \} = G(i_{V_2 V_1})(\inf\{ \hat{P} \in T^\rho(V_1) \})$, and so we have a global element of $G$.

The valuations $\nu^\rho, r$ arising from a quantum state via the probability $r$ construction (Eq. (3.21)), while giving subobjects of $\Sigma$, do not satisfy the stronger condition necessary to form global elements of $G$.

One way to avoid these issues arising from having to take infima of certain sets of projectors is to look at subobjects of $G$, rather than its global elements.

### 4.4 Subobjects of $G$

As described at the end of Section 3.2, every sieve-valued valuation $\nu$ on projectors induces a morphism $N^\nu : G \to \Omega$ in the topos of presheaves over $\mathcal{V}$, and hence corresponds to a subobject of $G$. This subobject $T^\nu$ is given at each stage $V$ by the set

$$T^\nu(V) = \{ \hat{P} \in \mathcal{L}(V) \mid \nu_V(\hat{P}) = \text{true}_V \}$$

(4.15)

This is the same construction as Eq. (4.17), but now considered as defining a subobject of $G$. In this subsection we discuss such subobjects, in particular those arising from sieve-valued valuations associated with a quantum state $\rho$ for the probability 1 and probability $r$ cases, as defined in equations (3.17) and (3.21).

#### 4.4.1 The probability 1 case

To obtain a subobject of $G$ from a quantum state $\rho$, we take at each stage $V_1$ the subset of the lattice of projectors $\mathcal{L}(V_1)$

$$T^\rho(V_1) := \{ \hat{P} \in V_1 \mid \text{tr}(\rho \hat{P}) = 1 \} \subset \mathcal{L}(V_1).$$

(4.16)

This is, of course, the subobject arising via Eq. (4.13) from the sieve-valued valuation $\nu^\rho$ associated with the quantum state $\rho$, defined in Eq. (3.17).

This forms a subobject of the coarse-graining presheaf since if $i_{V_2 V_1} : V_2 \to V_1$ then for any $\hat{P} \in \mathcal{L}(V_1)$

$$\text{tr}(\rho(G(i_{V_2 V_1})(\hat{P}))) \geq \text{tr}(\rho \hat{P}).$$

(4.17)
Hence it follows that
\[
G(i_{V_2V_1})(T^\rho(V_1)) \subseteq T^\rho(V_2)
\] (4.18)
and therefore $T^\rho$ is a genuine subobject of $G$. Also $L(V_2) \subseteq L(V_1)$ and for all $\hat{P}_2 \in L(V_2)$, $G(i_{V_2V_1})(\hat{P}_1) = \hat{P}_2$ where $\hat{P}_1, \hat{P}_2$ denote the same projector $\hat{P}$ thought of as belonging to $L(V_1)$ and $L(V_2)$ respectively. It follows that for all $\hat{P}_2 \in T^\rho(V_2)$ we have $\hat{P}_1 \in T^\rho(V_1)$, and therefore
\[
T^\rho(V_2) \subseteq G(i_{V_2V_1})(T^\rho(V_1))
\] (4.19)
and so this subobject obeys a functional composition principle $T^\rho(V_2) = G(i_{V_2V_1})(T^\rho(V_1))$ with an equality.

In this particular case, we can use the subobject $T$ of $G$ to give at each stage a subset $I^\rho(V)$ of the spectrum of the von Neumann algebra $V$ via
\[
I^\rho(V) := \{ \kappa \in \Sigma(V) \mid \kappa(\hat{P}) = 1 \ \forall \hat{P} \in T^\rho(V) \} \subset \Sigma(V)
\] (4.20)
Since the lattice $L(V)$ is complete, there exists a smallest projector in the set $T^\rho(V)$ as in the case of the global element of $G$: $\hat{Q} := \inf \{ \hat{P} \mid \hat{P} \in T^\rho(V) \}$. This is then the single projector at each stage defined by Eq. (4.13) for the case where $\nu$ is the sieve-valuation associated with the state $\rho$, and so the global element construction may be recovered in this case.

This then corresponds to a single augmented proposition at each stage, namely the collection of propositions "$A \in \Delta$" for each operator $\hat{A} \in V$ and Borel subset $\Delta$ such that $\hat{E}[A \in \Delta] = \hat{Q}$.

### 4.4.2 The Probability $r$ Case

As discussed in Section 4.3, not all sieve-valuations lead to global elements of $G$, or to subobjects of $\Sigma$. In particular, there is no global element of $G$ associated with the probability $r$ case for a quantum state $\rho$. However, we can take a subobject of $G$:
\[
T^{\rho,r}(V) := \{ \hat{P} \in V \mid \text{tr}(\rho \hat{P}) \geq r \}
\] (4.21)
where $0 \leq r \leq 1$. Heuristically, this is the set of propositions in $L(V)$ which are assigned a probability greater than $r$. Equation (4.17) still holds, and hence this still gives a genuine subobject of $G$.

The propositions $\{ \hat{P} \in V \mid \text{tr}(\rho \hat{P}) \geq r \}$ do not in general have a non-trivial infimum, (except when $r = 1$), and the infima will not obey the necessary matching conditions to allow us to construct a global element of $G$ in the same way as was possible in the $r = 1$ case.
4.4.3 Semantic Subobjects

This discussion of certain subobjects of $G$ induced via Eq. (4.13) by generalised valuations $\nu$ prompts us to ask what characterises subobjects of $G$ which can be induced in this way. The defining conditions for a generalised valuation $\nu$, Eqs. (3.9–3.12), give four properties of the corresponding subobject $T^\nu$ of $G$, defined according to Eq. (4.15).

1. **Functional composition:** this ensures that we have a genuine subobject $T^\nu$ of $G$, since it implies in particular that for all $\hat{P} \in T^\nu(V_1)$, so that $\nu(\hat{P}) = \text{true}_{V_1}$, it is true that $\nu_{V_2}(G(i_{V_2V_1})(\hat{P})) = \text{true}_{V_2}$, so $G(i_{V_2V_1})(T^\nu(V_1)) \subseteq T^\nu(V_2)$.

2. **Null proposition condition:** this implies that the always-false projector $\hat{0}_V$ never belongs to $T^\nu(V)$.

3. **Monotonicity:** for $\hat{P}, \hat{Q} \in \mathcal{L}(V)$ with $\hat{P} \leq \hat{Q}$, this condition implies that if $\hat{P} \in T^\nu(V)$ then also $\hat{Q} \in T^\nu(V)$; so $T^\nu(V)$ is required to be an upper set in $\mathcal{L}(V)$.

4. **Exclusivity:** if $\hat{P}, \hat{Q} \in \mathcal{L}(V)$ with $\hat{P}\hat{Q} = \hat{0}$ and $\hat{P} \in T^\nu(V)$ then $\hat{Q} \notin T^\nu(V)$.

Note that 1. and 2. are consequences of Eq. (3.9) and (3.10) respectively, and weaker than them. On the other hand, 3. and 4. are equivalent to Eq. (3.11) and Eq. (3.12) respectively.

We may wish to relax the exclusivity condition here (and the corresponding condition for generalised valuations) depending on the type of valuation being studied. As has already been pointed out, the exclusivity condition is not satisfied (and would not be expected to hold) for valuations where the probability required for a proposition to belong to the corresponding subobject of $G$ is less than a half.

Given the properties listed in 1.–4., we can then turn this around, and define a **semantic subobject** of $G$ as being a subobject satisfying these properties. Semantic subobjects then form a set of possible generalised valuations for our quantum theory.
4.5 Interval-Valued Valuations from Ideals

We now present another way of obtaining an interval-valued valuation on \( V \) which does not rely on the use of sieve-valuations and the coarse-graining presheaf.

We recall that the closed ideals in a commutative von Neumann algebra \( V \) are in one-to-one correspondence with the closed subsets of the spectrum \( \sigma(V) \) of \( V \). More precisely, according to the spectral theorem, the algebra \( V \) is isomorphic to the algebra \( C(\sigma(V)) \) of continuous, complex-valued functions on its spectrum; and a closed ideal in the algebra corresponds to the set of all functions in \( C(\sigma(V)) \) that vanish on the associated closed subset of \( \sigma(V) \).

Furthermore, according to a general result about extremely disconnected Hausdorff spaces (which \( \sigma(V) \) is), each closed subset of \( \sigma(V) \) differs from a unique clopen set by a meagre set. Therefore, any assignment of a closed ideal to each algebra in \( V \) will produce an interval-valued valuation, assigning to each \( V \) in \( V \) a clopen subset \( \Xi \) of its spectrum. The functions in the ideal are then precisely those that are disjoint to the characteristic function of \( \Xi \), \textit{i.e.}, those operators in \( V \) orthogonal to the projector \( \hat{P} \) that corresponds to the characteristic function of \( \Xi \).

Furthermore, according to a general result about extremely disconnected Hausdorff spaces (which \( \sigma(V) \) is), each closed subset of \( \sigma(V) \) differs from a unique clopen set by a meagre set. Therefore, any assignment of a closed ideal to each algebra in \( V \) will produce an interval-valued valuation, assigning to each \( V \) in \( V \) a clopen subset \( \Xi \) of its spectrum. The functions in the ideal are then precisely those that are disjoint to the characteristic function of \( \Xi \), \textit{i.e.}, those operators in \( V \) orthogonal to the projector \( \hat{P} \) that corresponds to the characteristic function of \( \Xi \).

We note that the lattice of closed, two-sided ideals in any non-commutative algebra \( N \) is an example of a quantale \( \square \). This structure can be viewed as the analogue of a spectrum for the non-commutative von Neumann algebra \( \mathcal{N} \), and as we have just shown, it represents another natural collection of interval-valued valuations in our framework.

\textbf{Example:} The subset \( \iota^\psi \) of the set \( B(\mathcal{H}) \) of bounded operators on some Hilbert space \( \mathcal{H} \) defined by

\begin{equation}
\iota^\psi = \{ \hat{A} \in B(\mathcal{H}) \mid \hat{A}\psi = 0 \} \quad (4.22)
\end{equation}

forms a closed left ideal since \( \hat{B} \hat{A}\psi = 0 \) for all \( \hat{B} \in B(\mathcal{H}) \), \( \hat{A} \in \iota^\psi \). This induces a two-sided ideal in each commutative von Neumann subalgebra \( V \):

\begin{equation}
\iota^\psi(V) = \{ \hat{A} \in V \mid \hat{A}\psi = 0 \}. \quad (4.23)
\end{equation}
We will now show that this ideal corresponds to the ‘true’ subobject of $\Sigma$ described in Example 1 of Section 4.2 for the quantum state $\psi$.

We will denote the set of projectors in $\iota^\psi(V)$ by $P(\iota^\psi(V))$. If the projectors $\hat{Q}_1, \hat{Q}_2 \in P(\iota^\psi(V))$, so that $\hat{Q}_1 \psi = 0 = \hat{Q}_2 \psi$, then we also have $(\hat{Q}_1 + \hat{Q}_2) \psi = 0$, so $(\hat{Q}_1 + \hat{Q}_2) \in P(\iota^\psi(V))$. It follows that there exists a largest projector $\hat{Q}_{\max} \in \iota^\psi(V)$

$$\hat{Q}_{\max} = \text{sup} P(\iota^\psi(V)).$$ \hspace{1cm} (4.24)

As was noted above, a projector in $V$ corresponds to a characteristic function in $C(\sigma(V))$ of some clopen subset $\Xi \subset \sigma(V)$, and the set of functions disjoint to a characteristic function are the functions in the ideal. The ideal in $V$ is then associated with the subset of $\sigma(V)$ for which the projector $(\hat{1} - \hat{Q}_{\max})$ corresponds to the characteristic function i.e., the set $\{\kappa \in \sigma(V) | \kappa(\hat{1} - \hat{Q}_{\max}) = 1\}$. We also note that $(\hat{1} - \hat{Q}_{\max}) \psi = \psi$, and so $\langle \psi | (\hat{1} - \hat{Q}_{\max}) | \psi \rangle = 1$, and indeed $(\hat{1} - \hat{Q}_{\max})$ is the smallest projector with this property. This therefore corresponds to the subobject of $\Sigma$ given by $I^\rho$ in Eq. (4.4) for the state $\rho$ on $V$ given by $\rho(A) = \langle \psi | A | \psi \rangle$.

5 Conclusions

In this paper, we have extended the topos-theoretic perspective on the assignment of values to quantities in quantum theory to the base category $V$ of commutative von Neumann algebras; a category which generalizes the categories of contexts $O$ and $W$ used in [1, 2]. As we have seen, the main results of [1, 2]—both the leading ideas, and the mathematical constructions—can be adapted to the von Neumann algebra case. (Though we have not spelt out all the details of this adaptation, piece by piece, one can check the details for the topics we have omitted—for example, classical analogues—and general motivations for sieve-valued valuations, as discussed in [2].)

This adaptation of our results to $V$ is straightforward, except that, as noted in Section 3.1, we need to be careful about two issues: (i) about interpreting a proposition “$A \in \Delta$” relative to a von Neumann algebra $V$ as a context; and (ii) about the properties of spectral topologies. The upshot is that: (i) we interpret a projector $\hat{P}$ at a context $V$ in terms of all “$A \in \Delta$”, with $A \in V$ and $\hat{E}[A \in \Delta] = \hat{P}$; and (ii) $G$ is isomorphic to the clopen power object Clo$\Sigma$ of the spectral presheaf $\Sigma$. 25
Accordingly, we conclude that the base category $\mathcal{V}$ of commutative von Neumann algebras is as natural a basis for developing the topos-theoretic treatment of the values of quantities in quantum theory, as were our previous categories $\mathcal{O}$ and $\mathcal{W}$; indeed, in certain respects $\mathcal{V}$ is a better basis, since it includes the others in a natural way. In particular, it is a natural basis for addressing the various topics listed in Section 6 of [1].

In this paper, we have addressed one such topic, using $\mathcal{V}$: that of interval-valued valuations. As we saw in Section 4, there are close connections between our sieve-valued valuations, and the assignment to quantities of subsets of their (operators') spectra, and so also the assignments to commutative algebras of subsets of their spectra. We displayed these connections in various ways: in terms of subobjects of $\Sigma$, in terms of global elements of $G$, and in terms of subobjects of $\mathcal{G}$. One main idea in making these connections was the set $T^\nu(V)$ of projectors $P \in V$ that are “wholly true” according to the sieve-valued valuation $\nu$: which for the case of $\nu$ given by a quantum state $\rho$ is essentially the familiar quantum-theoretic idea of the support of a state. Finally, we noted in Section 4.5 that once we use $\mathcal{V}$, rather than $\mathcal{O}$ or $\mathcal{W}$, as our base category of contexts, we can use ideals in the von Neumann algebras to define interval-valued valuations in a natural way: though again, care is needed about the spectral topologies.
