Strongly compact cardinals and ordinal definability

Gabriel Goldberg

July 2, 2021

Abstract

This paper explores several topics related to Woodin’s HOD conjecture. We improve the large cardinal hypothesis of Woodin’s HOD dichotomy theorem from an extendible cardinal to a strongly compact cardinal. We show that assuming there is a strongly compact cardinal and the HOD hypothesis holds, there is no elementary embedding from HOD to HOD, settling a question of Woodin. We show that the HOD hypothesis is equivalent to a uniqueness property of elementary embeddings of levels of the cumulative hierarchy. We prove that the HOD hypothesis holds if and only if every regular cardinal above the first strongly compact cardinal carries an ordinal definable \( \omega \)-Jónsson algebra. We show that if \( \kappa \) is supercompact, the HOD hypothesis holds, and HOD satisfies the Ultrapower Axiom, then \( \kappa \) is supercompact in HOD.

1 Introduction

The Jensen covering theorem \cite{Jensen} states that if \( 0^\# \) does not exist, then every uncountable set of ordinals is covered by a constructible set of the same cardinality. This leads to a strong dichotomy for the cardinal correctness of the constructible universe \( L \):

**Theorem** (Jensen). Exactly one of the following holds:

1. For all singular cardinals \( \lambda \), \( \lambda \) is singular in \( L \) and \( (\lambda^+)^L = \lambda^+ \).
2. Every infinite cardinal is strongly inaccessible in \( L \).

The proof of this theorem and its generalizations to larger canonical inner models tend to make heavy use of the special structure of such models. By completely different techniques, however, Woodin \cite{Woodin} showed that such a dichotomy holds for the (noncanonical) inner model HOD under large cardinal hypotheses.

**Theorem** (Woodin’s HOD dichotomy). If \( \kappa \) is extendible, exactly one of the following holds:

1. For all singular cardinals \( \lambda > \kappa \), \( \lambda \) is singular in HOD and \( (\lambda^+)^{HOD} = \lambda^+ \).
2. Every regular cardinal greater than or equal to \( \kappa \) is measurable in HOD.

Woodin’s HOD conjecture states that conclusion \([1]\) which in this context is known as the HOD hypothesis\([3]\) is provable from large cardinal axioms.

The first few theorems of this paper (Section 2) show that the HOD dichotomy in fact takes hold far below the least extendible cardinal.

\[1\]In the context of bare ZFC (without large cardinal axioms), the HOD hypothesis states that there is a proper class of regular cardinals that are not \( \omega \)-strongly measurable in HOD. Conceivably the HOD hypothesis is provable in ZFC.
Theorem. If $\kappa$ is strongly compact, exactly one of the following holds:

1. For all singular cardinals $\lambda > \kappa$, $\lambda$ is singular in HOD and $(\lambda^+)^{\text{HOD}} = \lambda^+$.
2. All sufficiently large regular cardinals are measurable in HOD.

We prove this as a corollary of a theorem establishes a similar dichotomy for a fairly broad class of inner models. An inner model $N$ of ZFC is $\omega_1$-club amenable if for all ordinals $\delta$ of uncountable cofinality, the $\omega_1$-club filter $F$ on $\delta$ satisfies $F \cap N \in N$.

Theorem 2.9. Assume $N$ is $\omega_1$-club amenable and $\kappa$ is $\omega_1$-strongly compact. Either all singular cardinals $\lambda > \kappa$ are singular in $N$ and $(\lambda^+)^N = \lambda^+$, or all sufficiently large regular cardinals are measurable in $N$.

Note that we use a somewhat weaker large cardinal hypothesis than strong compactness: a cardinal $\kappa$ is $\omega_1$-strongly compact if every $\kappa$-complete filter extends to an $\omega_1$-complete ultrafilter.

The main theorem of [4] states that if $j_0, j_1 : V \rightarrow M$ are elementary embeddings, then $j_0 \upharpoonright \text{Ord} = j_1 \upharpoonright \text{Ord}$. Section 3 turns to the relationship between local forms of this theorem and Woodin's HOD conjecture.

Theorem 3.5. Assume $\kappa$ is an extendible cardinal. Then the following are equivalent:

1. The HOD hypothesis.
2. For all regular $\delta \geq \kappa$ and all sufficiently large $\alpha$, any elementary embeddings $j_0, j_1 : V_\alpha \rightarrow M$ with $j_0(\delta) = j_1(\delta)$ and $\sup j_0[\delta] = \sup j_1[\delta]$ agree on $\delta$.

We also prove a related theorem that connects the failure of the HOD hypothesis to definable infinitary partition properties, choiceless large cardinals, and sharps.

A cardinal $\lambda$ is Jónsson if for all $f : [\lambda]^{<\omega} \rightarrow \lambda$, there is a proper subset $A$ of $\lambda$ of cardinality $\lambda$ such that $f(s) = s$ for all $s \in [A]^{<\omega}$. A cardinal $\lambda$ is constructibly Jónsson if this holds for all constructible functions $f : [\lambda]^{<\omega} \rightarrow \lambda$, there is a proper subset $A$ of $\lambda$ of cardinality $\lambda$ such that $f(s) = s$ for all $s \in [A]^{<\omega}$.

Proposition. The following are equivalent:

- $\exists^* \text{ exists}.
- Every uncountable cardinal is constructibly Jónsson.
- Some uncountable cardinal is constructibly Jónsson.

A cardinal $\lambda$ is $\omega$-Jónsson if for all $f : [\lambda]^{<\omega} \rightarrow \lambda$, there is a proper subset $A$ of $\lambda$ of cardinality $\lambda$ such that $f(s) = s$ for all $s \in [A]^{<\omega}$. Recall Kunen’s theorem that there is no elementary embedding $j : V \rightarrow V$. Kunen proved his theorem by showing that if $j(\lambda) = \lambda$, then $\lambda$ is $\omega$-Jónsson. He then cites the following combinatorial theorem:

Theorem (Erdős-Hajnal). There are no $\omega$-Jónsson cardinals.

A cardinal $\lambda$ is definably $\omega$-Jónsson if for all ordinal definable functions $f : [\lambda]^{<\omega} \rightarrow \lambda$, there is a proper subset $A$ of $\lambda$ of cardinality $\lambda$ such that $f(s) = s$ for all $s \in [A]^{<\omega}$.

Theorem 3.7. Assume $\kappa$ is strongly compact. Then the following are equivalent:
• The HOD hypothesis fails.
• All sufficiently large regular cardinals are definably ω-Jónsson.
• Some regular cardinal above κ is definably ω-Jónsson.

In Section 3.3, we use techniques drawn from the proof of the main theorem of [4] to answer a decade-old question of Woodin (implicit in [6]). Recall Kunen’s famous theorem relating the rigidity of $L$ to $0^\#$:

**Theorem** (Kunen). If $0^\#$ does not exist, then there is no nontrivial elementary embedding from $L$ to $L$.

Here we prove an analog for HOD, replacing the assumption that $0^\#$ does not exist with the HOD hypothesis.

**Theorem 3.9.** Assume there is an $\omega_1$-strongly compact cardinal. If the HOD hypothesis holds, then there is no nontrivial elementary embedding from HOD to HOD.

Section 4.1 turns to the question of the structure of strongly compact cardinals in the HOD of a model of determinacy. In this context, something close to the failure of the HOD hypothesis holds, and yet we will show that HOD still has certain local covering properties in regions of strong compactness. One consequence of our analysis is the following theorem on the equivalence of strong compactness and $\omega_1$-strong compactness in HOD assuming Woodin’s HOD ultrafilter conjecture: under $\text{AD} + V = L(P(\mathbb{R}))$, every $\omega_1$-complete ultrafilter of HOD generates an $\omega_1$-complete filter in $V$. (The HOD ultrafilter conjecture is true in $L(\mathbb{R})$ and more generally in all inner models of determinacy amenable to the techniques of contemporary inner model theory.)

**Theorem 4.2.** Assume $\text{AD}^+$, $V = L(P(\mathbb{R}))$, and the HOD-ultrafilter conjecture. Suppose $\kappa < \Theta$ is a regular cardinal and $\delta \geq \kappa$ is a HOD-regular ordinal. Then $\kappa$ is $\delta$-strongly compact in HOD if and only if $\kappa$ is $(\omega_1, \delta)$-strongly compact in HOD.

This should be compared with a theorem of [3] stating that under the Ultrapower Axiom, for any regular cardinal $\delta$, the least $(\omega_1, \delta)$-strongly compact cardinal is $\delta$-strongly compact. It is natural to conjecture that assuming AD, if $V = L(P(\mathbb{R}))$, then HOD is a model of the Ultrapower Axiom.

The final section (Section 4.2) explores the absoluteness of large cardinals to HOD in the context of a strongly compact cardinal. Woodin [6] showed:

**Theorem** (Woodin). Suppose $\kappa$ is extendible and the HOD hypothesis holds. Then $\kappa$ is extendible in HOD.

By results of Cheng-Friedman-Hamkins [1], the least supercompact cardinal need not be weakly compact in HOD. Here we show that nevertheless, HOD is very close to an inner model with a supercompact cardinal.

**Theorem 4.12.** Suppose $\kappa$ is supercompact and the HOD hypothesis holds. Then $\kappa$ is supercompact in an inner model $N$ of ZFC such that $\text{HOD} \subseteq N$ and $\text{HOD}^\infty \cap N \subseteq \text{HOD}$.

As a corollary, we show:

**Theorem 4.13.** Suppose $\kappa$ is supercompact, the HOD hypothesis holds, and HOD satisfies the Ultrapower Axiom. Then $\kappa$ is supercompact in HOD.
2 On the HOD dichotomy

2.1 Strongly measurable cardinals

For any regular cardinal $\gamma$ and any ordinal $\delta$ of cofinality greater than $\gamma$, $C_\delta$ denotes the closed unbounded filter on $\delta$, $S^\delta_\gamma$ denotes the set of ordinals less than $\delta$ of cofinality $\gamma$, and $C_{\delta,\gamma}$ denotes the filter generated by $C_\delta \cup \{S^\delta_\gamma\}$, or equivalently the filter generated by the $\gamma$-closed unbounded subsets of $\delta$. Similarly, $S^\delta_\gamma < \gamma = \bigcup_{\lambda < \gamma} S^\delta_\lambda$ and $C_{\delta,<\gamma}$ denotes the filter generated by $C_\delta \cup \{S^\delta_\gamma\}$.

A filter $F$ is $\gamma$-saturated if any collection of $F$-almost disjoint $F$-positive sets has cardinality less than $\gamma$. The saturation of a filter is a measure of how close the filter is to being an ultrafilter.

**Lemma 2.1** (Ulam). Suppose $F$ is a $(2^\gamma)^+$-complete $\gamma$-weakly saturated filter. Then $F$ is the intersection of fewer than $\gamma$-many ultrafilters. \(\square\)

Note that if a $\gamma$-complete filter $F$ is the intersection of fewer than $\gamma$-many ultrafilters, then the underlying set of $F$ can be partitioned into atoms of $F$. If $\nu < \delta$ are regular cardinals, $\delta$ is $\nu$-strongly measurable in an inner model $N$ if $C_{\delta,<\gamma} \cap N$ belongs to $N$ and is $\gamma$-weakly saturated in $N$ for some $N$-cardinal $\gamma$ such that $(2^\gamma)^N < \delta$.

**Lemma 2.2.** Suppose $N$ is an inner model of ZFC, $\nu < \delta$ are regular cardinals, and $\eta$ is the least $N$-cardinal such that $(2^\eta)^N \geq \delta$. Then the following are equivalent:

- $\delta$ is $\nu$-strongly measurable in $N$.
- For some $\gamma < \eta$, $C_{\delta,<\gamma} \cap N$ can be written as an intersection of fewer than $\gamma$-many ultrafilters of $N$.
- For some $\gamma < \eta$, $\delta$ can be partitioned into $\gamma$-many $C_{\delta,<\gamma}$-positive sets $\langle S_\alpha : \alpha < \nu \rangle \in N$ such that $(C_{\delta,<\gamma} \upharpoonright S_\alpha) \cap N$ is an ultrafilter in $N$. \(\square\)

2.2 The HOD dichotomy

Suppose $M$ is an inner model, $\lambda$ is a cardinal, and $\lambda'$ is an $M$-cardinal. An inner model $M$ has the $(\lambda, \lambda')$-cover property if for every set $\sigma \subseteq M$ of cardinality less than $\lambda$, there is a set $\tau \in M$ of $M$-cardinality less than $\lambda'$ such that $\sigma \subseteq \tau$. We refer to the $(\lambda, \lambda)$-cover property as the $\lambda$-cover property.

**Proposition 2.3.** Suppose $\kappa$ is strongly compact. Then exactly one of the following holds:

- (1) All sufficiently large regular cardinals are measurable in HOD.
- (2) HOD has the $\kappa$-cover property.

**Proof.** There are two cases.

**Case 1.** There is a HOD-cardinal $\eta$ such that for all regular cardinals $\delta$, $C_{\delta,<\kappa} \cap \text{HOD}$ is $\eta$-saturated in $\text{HOD}$.

In this case, Lemma 2.1 implies that all regular cardinals $\delta > (2^\eta)^\text{HOD}$ are measurable in HOD.
Case 2. For every HOD-cardinal $\eta$, there is a regular cardinal $\delta$ such that $\mathcal{C}_{\delta, < \kappa} \cap \text{HOD}$ is not $\eta$-saturated in HOD.

We claim that HOD has the $\kappa$-cover property. For this, it suffices to show that for all $\eta$, there is a $\kappa$-complete fine ultrafilter $\mathcal{U}$ on $P_\kappa(\eta)$ such that $\text{HOD} \cap P_\kappa(\eta) \in \mathcal{U}$. Then for each $\sigma \subseteq \eta$ with $|\sigma| < \kappa$, the set $\{ \tau \in P_\kappa(\eta) : \sigma \subseteq \tau \}$ belongs to $\mathcal{U}$ by fineness and $\kappa$-completeness. Thus this set meets $\text{HOD} \cap P_\kappa(\eta)$, which yields a set $\tau \in \text{HOD}$ such that $|\tau|^{\text{HOD}} < \kappa$ and $\sigma \subseteq \tau$.

Fix an ordinal $\eta$. Let $\delta$ be a regular cardinal such that $\mathcal{C}_{\delta, < \kappa} \cap \text{HOD}$ is not $\eta$-saturated in HOD. Let $\mathcal{S} = \{ S_\alpha : \alpha < \eta \}$ be an ordinal definable partition of $S^\delta_{\kappa}$ into stationary sets.

Since $\kappa$ is strongly compact, there is an elementary embedding $j : V \rightarrow M$ with critical point $\kappa$ such that $M$ has the $(\delta^+, j(\kappa))$-cover property. Let $\delta_s = \sup j[\delta]$. This implies that $\text{cf}^M(\delta_s) < j(\kappa)$. Fix a closed unbounded set $C \subseteq \delta_s$ such that $C \in M$ and $|C|^M < j(\kappa)$.

Let $\mathcal{T} = \{ T_\beta : \beta < j(\eta) \} = j(\mathcal{S})$. Let

$$\sigma = \{ \beta < j(\eta) : T_\beta \cap \delta_s \text{ is stationary in } M \}$$

Then $\sigma$ is ordinal definable in $M$ since $\mathcal{T}$ is. Notice that for all $\alpha < \eta$, $j[S_\alpha]$ is a stationary subset of $\delta_s$: $j$ is continuous on $S^\delta_{\kappa}$, and so there is a continuous increasing cofinal function $f : \delta \rightarrow \delta_s$ such that $j[S_\alpha] = f[S_\alpha]$. Since $j[S_\alpha] \subseteq T_{j(\alpha)}$, $j(\alpha) \in \sigma$. On the other hand, for each $\beta \in \sigma$, let $f(\beta) = \min(T_\beta \cap C)$. Then $f : \sigma \rightarrow C$ is an injection, so $|\sigma|^M < j(\kappa)$. In other words, $\sigma \in j(P_\kappa(\eta))$.

Let $\mathcal{U}$ be the ultrafilter on $P_\kappa(\eta)$ derived from $j$ using $\sigma$. Then $\text{HOD} \cap P_\kappa(\eta) \in \mathcal{U}$ since $\sigma$ is ordinal definable in $M$. Moreover $\mathcal{U}$ is fine since $j[\eta] \subseteq \sigma$. Finally $\mathcal{U}$ is $\kappa$-complete since $\text{crit}(j) = \kappa$.

This finishes the proof that HOD has the $\kappa$-cover property.

The proof of Proposition 2.3 shows that if HOD does not cover $V$, then sufficiently large regular cardinals are measurable in HOD in a strong sense.

Proposition 2.4. Suppose $\kappa$ is strongly compact. Then exactly one of the following holds:

(1) For some $\gamma$, for all ordinals $\delta$ with $\text{cf}(\delta) \geq \gamma$, $\mathcal{C}_{\delta, < \kappa} \cap \text{HOD}$ is the intersection of fewer than $\gamma$-many ultrafilters in HOD.

(2) HOD has the $\kappa$-cover property.

For any OD set $A \subseteq \text{OD}$, let $|A|^\text{OD}$ denote the minimum ordertype of an ordinal definable wellorder of $A$. For any set $X$, let $\beta(X)$ denote the set of ultrafilters on $X$.

Proposition 2.5. Suppose $\kappa$ is strongly compact and HOD has the $\kappa$-cover property. Then for any cardinal $\lambda \geq \kappa$, HOD has the $\{ \leq \lambda, \theta \}$-cover property where $\theta = |\text{POD}(\beta(\lambda))|^\text{OD}$.

Proof. We may assume that $\lambda$ is a regular cardinal. Let $\mathcal{U}$ be a $\kappa$-complete fine ultrafilter on $P_\lambda(\lambda)$. Note that $\sigma$ is covered by a set of size less than $j_\mathcal{U}(\kappa)$ in $M_\mathcal{U}$. Since HOD $^{M_\mathcal{U}}$ has the $j_\mathcal{U}(\kappa)$-cover property in $M_\mathcal{U}$, $\sigma$ is in fact covered by a set of size less than $j_\mathcal{U}(\kappa)$ in HOD $^{M_\mathcal{U}}$. But HOD $^{M_\mathcal{U}} \subseteq \text{HOD}_\mathcal{U}$, and so $\sigma$ is covered by a set of size less than $(2^\lambda)^+$ in HOD $^{M_\mathcal{U}}$. But HOD $^{M_\mathcal{U}}$ is a $\theta$-cc extension of HOD and $\theta \geq (2^\lambda)^+$, so $\sigma$ is covered by a set of size less than $\theta$ in HOD.

Corollary 2.6. If $\kappa$ is strongly compact, either all sufficiently large regular cardinals are measurable in HOD or HOD has the $\lambda$-cover property for all strong limit cardinals $\lambda \geq \kappa$. □
In particular, for all strong limit singular cardinals \( \lambda \geq \kappa \), \( \lambda \) is singular in HOD and \( \lambda^{+\text{HOD}} = \lambda^+ \). But in fact one can prove this for arbitrary singular cardinals above \( \kappa \). The proof is more general in two ways. First, it uses a weaker large cardinal hypothesis: a cardinal \( \kappa \) is \( \omega_1 \)-\textit{strongly compact} if every \( \kappa \)-complete filter extends to a countably complete ultrafilter.

Second, it applies to a broader class of models than just HOD: an inner model \( N \) of \( \text{ZFC} \) is \( \omega \)-\textit{club amenable} if for every ordinal \( \delta \) of uncountable cofinality, \( \mathcal{C}_{\delta,\omega} \cap N \in N \). The proof of the following lemma is similar to that of Proposition 2.3.

**Lemma 2.7.** Suppose \( N \) is \( \omega \)-\textit{club amenable} and \( \kappa \) is \( \omega_1 \)-\textit{strongly compact}. Then one of the following holds:

1. All sufficiently large regular cardinals are measurable in \( N \).
2. \( N \) has the \( (\omega_1, \kappa) \)-\textit{cover property}.

**Proof.** The proof splits into cases as in Proposition 2.3 applied in \( N \) to \( \mathcal{C}_{\delta,\omega} \cap N \in N \).

**Case 1.** There is an \( N \)-cardinal \( \eta \) such that for all regular cardinals \( \delta \), \( \mathcal{C}_{\delta,\omega} \cap N \) is \( \eta \)-saturated in \( N \).

Then for all sufficiently large regular cardinals \( \delta \), \( \delta \) is measurable in \( N \) by Lemma 2.1 applied in \( N \) to \( \mathcal{C}_{\delta,\omega} \cap N \in N \).

**Case 2.** For every \( N \)-cardinal \( \eta \), there is a regular cardinal \( \delta \) such that \( \mathcal{C}_{\delta,\omega} \cap N \) is not \( \eta \)-saturated in \( N \).

In this case, one shows that for all \( \lambda \geq \kappa \), there is a countably complete fine ultrafilter \( \mathcal{U} \) on \( P_\kappa(\lambda) \) such that \( N \cap P_\kappa(\lambda) \in \mathcal{U} \). It follows that every countable set \( \sigma \subseteq \lambda \) belongs to some \( \tau \in N \cap P_\kappa(\lambda) \).

**Theorem 2.8.** Suppose \( \nu \) is a regular cardinal and \( N \) is an \( \omega \)-\textit{club amenable inner model} with the \( (\omega_1, \nu) \)-\textit{cover property}. Then for all \( N \)-regular \( \delta \geq \nu \), \( \text{cf}(\delta) = |\delta| \).

**Proof.** Let \( A = (S^\delta_\text{cf})^N \). The \( (\omega_1, \nu) \)-\textit{cover property} of \( N \) implies that \( S^\delta_\text{cf} \subseteq A \), which is all we will use. Fix \( (\xi_\alpha : \alpha \in A) \in N \) such that \( \xi_\alpha \) is a closed cofinal subset of \( \xi \) of ordertype less than \( \nu \). For each \( \alpha < \delta \), let \( \beta_\alpha \) denote the least ordinal such that for a stationary set of \( \xi \in S^\delta_\text{cf} \), \( \xi \cap [\alpha, \beta_\alpha) \neq \emptyset \). One can prove that \( \beta_\alpha \) exists for all \( \alpha < \delta \) by applying Fodor’s lemma to the function \( f(\xi) = \text{min}(\xi \setminus \alpha) \). Define a continuous increasing sequence \( (\epsilon_\alpha : \alpha < \delta) \) by setting \( \epsilon_{\alpha+1} = \beta_{\epsilon_\alpha} \), taking suprema at limit steps; these suprema are always below \( \delta \) because the sequence belongs to \( N \) and \( \delta \) is regular in \( N \).

For each \( \xi \in A \), let \( \sigma_\xi = \{ \alpha < \delta : \epsilon_\xi \cap [\epsilon_\alpha, \epsilon_{\alpha+1}) \neq \emptyset \} \)

Note that \( |\sigma_\xi| < \nu \) since \( |\epsilon_\xi| < \nu \). Moreover for all \( \alpha \), the set \( S_\alpha = \{ \xi \in A : \alpha \in \sigma_\xi \} \) is stationary. Let \( C \subseteq \delta \) be a closed cofinal set of ordertype \( \text{cf}(\delta) \). For any \( \alpha < \delta \), there is some \( \xi \in S_\alpha \cap C \), which means that \( \alpha \in \sigma_\xi \). This implies that \( \delta = \bigcup_{\xi \in C} \sigma_\xi \).

Thus \( |\delta| = |C| \cdot \sup_{\xi \in C} |\sigma_\xi| \).

If \( |C| < \nu \), then since \( \nu \) is regular, \( \sup_{\xi \in C} |\sigma_\xi| < \nu \) and hence \( |\delta| < \nu \), contradicting that \( \delta \geq \nu \). Therefore \( |C| \geq \nu \). Therefore \( |\delta| = |C| \cdot \sup_{\xi \in C} |\sigma_\xi| = |C| \cdot |\nu| = |C| = \text{cf}(\delta) \).

**Corollary 2.9.** Suppose \( \kappa \) is \( \omega_1 \)-\textit{strongly compact} and \( N \) is an \( \omega \)-\textit{club amenable inner model}. Either all sufficiently large regular cardinals are measurable in \( N \) or every singular cardinal \( \lambda \) greater than \( \kappa \) is singular in \( N \) and \( \lambda^{+N} = \lambda^+ \).
We now state some reformulations of the failure of the HOD hypothesis.

**Theorem 2.10.** If \( \kappa \) is strongly compact, the following are equivalent to the failure of the HOD hypothesis:

1. There is a regular cardinal \( \delta \geq \kappa \) with a stationary subset \( S \subseteq S^\delta_{<\kappa} \) that admits no ordinal definable partition into \( \delta \)-many stationary sets.

2. There is an \( \omega \)-strongly measurable cardinal above \( \kappa \).

3. For some regular \( \gamma < \kappa \), there is a \( \gamma \)-strongly measurable cardinal above \( \kappa \).

4. For all regular \( \gamma < \kappa \), all sufficiently large regular cardinals are \( \gamma \)-strongly measurable.

5. For some cardinal \( \lambda \), for all regular \( \gamma < \kappa \) and all \( \nu \) with \( \text{cf}(\nu) > \gamma \), \( C_{\nu,\gamma} \cap \text{HOD} \) is \( \lambda \)-saturated in \( \text{HOD} \).

**Proof.** We first show that (1) implies that the HOD hypothesis is false. By the proof of Proposition 2.3, if the HOD hypothesis fails, then (5) holds. Since each item easily implies all the previous ones, the theorem easily follows.

It remains to show that (1) implies the failure of the HOD hypothesis, or in other words, that the HOD hypothesis implies that every stationary subset \( S \subseteq S^\delta_{<\kappa} \) splits into \( \delta \)-many subsets. This follows from the proof of the Solovay splitting theorem and the fact that \( (S^\delta_{<\kappa})_{\text{HOD}} = S^\delta_{<\kappa} \).

It is easy to see that if the HOD hypothesis fails, then every regular cardinal \( \delta \) contains an \( \omega \)-club of ordinals that are strongly inaccessible in HOD. In fact, this alone implies a stronger conclusion.

**Theorem 2.11.** Suppose \( N \) is an inner model and \( \delta \) is a regular cardinal such that \( \text{Reg}_N \cap \delta \) contains an \( \omega \)-club. Then \( \text{Reg}_N \cap \delta \) contains a club.

**Proof.** Assume towards a contradiction that \( \text{Sing}_N \cap \delta \) is stationary. Since the cofinality function as computed in \( N \) is regressive, there is an ordinal \( \gamma \) that is regular in \( N \) such that \( (S^\delta_{<\gamma})_N \) is stationary. Let \( \gamma \) be the least such ordinal and let \( S = (S^\delta_{<\gamma})_N \). We claim \( \text{cf}(\gamma) = \omega \).

Choose \( \langle \xi : \xi \in S \rangle \in N \) such that \( c_\xi \) is a closed unbounded subset of \( \xi \) with ordertype \( \gamma \). Consider the set \( T \) of \( \nu \in S^\delta_{<\gamma} \) such that there is some \( \xi \geq \nu \) in \( S \) such that \( c_\xi \cap \nu \) is cofinal in \( \nu \). Then \( T \) is stationary. To see this, fix a closed unbounded set \( C \subseteq \delta \), and we will show that \( C \cap T \neq \emptyset \). Fix \( \xi \in S \cap \text{acc}(C) \). Since \( \text{cf}(\xi) > \omega \), \( C \cap \text{acc}(c_\xi) \) is closed unbounded in \( \gamma \), and so there is some \( \nu \in C \cap \text{acc}(c_\xi) \cap S^\delta_{<\omega} \). By definition, \( \nu \in T \). So \( C \cap T \neq \emptyset \), as claimed.

Note that \( T \subseteq (S^\delta_{<\gamma})_N \), so \( (S^\delta_{<\gamma})_N \) is stationary. Again applying Fodor’s lemma, there is an \( N \)-regular ordinal \( \gamma' < \gamma \) such that \( (S^\delta_{<\gamma'})_N \) is stationary, and this contradicts the minimality of \( \gamma \).

Since \( (S^\delta_{<\gamma})_N \) is a stationary subset of \( S^\delta_{<\gamma} \), its intersection with any \( \omega \)-club is stationary. This implies that \( (S^\delta_{<\gamma})_N \cap \text{Reg}_N \) is stationary, which is a contradiction.

**Corollary 2.12.** Assume there is an \( \omega_1 \)-strongly compact cardinal \( \kappa \) and \( N \) is an \( \omega \)-club amenable model such that \( \lambda^+ < \lambda^+ \) for some singular \( \lambda > \kappa \). Then all sufficiently large regular cardinals contain a closed unbounded set of \( N \)-inaccessible cardinals.
Proof. Suppose \( \delta \) is \( \omega \)-strongly measurable in \( N \), and we will show that there is an \( \omega \)-club of \( N \)-regular ordinals below \( \delta \). Suppose not. Then \( \text{Sing}^N \) is \( C_{\delta, \omega} \)-positive. It follows that there is a set \( S \in N \) such that \( S \subseteq \text{Sing}^N \) and \( C_{\delta, \omega} \upharpoonright S \) is a normal ultrafilter in \( N \). This is a contradiction since \( \text{Reg}^N \cap \delta \) belongs to any normal ultrafilter of \( N \) on \( \delta \).

Since all sufficiently large regular cardinals are \( \omega \)-strongly measurable in \( N \) by Corollary 2.9, the desired conclusion follows from Theorem 2.11.

Corollary 2.13. Assume there is an \( \omega_1 \)-strongly compact cardinal and the HOD hypothesis fails. Then all sufficiently large regular cardinals contain a closed unbounded set of HOD-inaccessible cardinals.

3 Embeddings of HOD

3.1 Uniqueness of elementary embeddings

We prove that the HOD Hypothesis is equivalent to a uniqueness property of elementary embeddings that makes no mention of ordinal definability.

Lemma 3.1. If \( \kappa \) is supercompact, then for all regular \( \delta \geq \kappa \) and all \( \gamma > \delta \), the set

\[
\{ \sup j(\delta) : \delta < \gamma < \delta, \ j : V_\gamma \rightarrow V_\gamma \text{ is elementary, and } j(\delta) = \delta \}
\]

is stationary in \( \delta \).

Lemma 3.2. Suppose \( \kappa \) is strongly compact and for arbitrarily large regular cardinals \( \delta \geq \kappa \), the set \( \{ \alpha < \delta : \text{cf}^{\text{HOD}}(\alpha) < \kappa \} \) is stationary. Then the HOD hypothesis holds.

Proof. This follows from Proposition 2.4.

Definition 3.3. Suppose \( j_0, j_1 : M \rightarrow N \) are elementary embeddings. For any ordinal \( \delta \in M \), \( j_0 \) and \( j_1 \) are similar at \( \delta \) if \( \sup j_0[\delta] = \sup j_1[\delta] \) and \( j_0(\delta) = j_1(\delta) \). For any ordinal \( \delta' \in N \), \( j_0 \) and \( j_1 \) are similar below \( \delta' \) if there is some \( \delta \in M \) such that \( j_0(\delta) = j_1(\delta) = \delta' \) and \( j_0 \) and \( j_1 \) are similar at \( \delta \).

Theorem 3.4. Suppose \( \kappa \) is a supercompact cardinal. Then the following are equivalent:

1. The HOD hypothesis holds.

2. For all regular \( \delta \geq \kappa \), for all sufficiently large \( \gamma \), if \( j_0, j_1 : V_\gamma \rightarrow V_\gamma \) are similar below \( \delta \), then \( j_0 \upharpoonright \delta = j_1 \upharpoonright \delta \).

Proof. Assume (1) holds. Let \( \langle S_\alpha : \alpha < \delta \rangle \) be the least partition of \( S_\delta^\delta \) into stationary sets in the canonical wellorder of HOD. For sufficiently large ordinals \( \gamma \), \( \langle S_\alpha : \alpha < \delta \rangle \) is definable from \( \delta \) in \( V_\gamma \). Suppose \( j : V_\gamma \rightarrow V_\gamma \) and \( j(\delta) = \delta \). Then \( \langle S_\alpha : \alpha < \delta \rangle \) is in the range of \( j \) since \( \delta \) is. As a consequence, \( j(\delta) \) is the set of \( \alpha < \delta \) such that \( S_\alpha \) reflects to \( \sup j(\delta) \).

Conversely, suppose (2) holds. Fix a regular cardinal \( \delta > \kappa \). For each \( \gamma > \delta \), define

\[
S_\gamma = \{ \sup j(\delta) : j : V_\gamma \rightarrow V_\gamma \text{ is elementary and } j(\delta) = \delta \}
\]

Fix an ordinal \( \gamma \) sufficiently large that if \( j_0, j_1 : V_\gamma \rightarrow V_\gamma \) are elementary embeddings with \( j_0(\delta) = j_1(\delta) = \delta \) and \( \sup j_0[\delta] = \sup j_1[\delta] \), then \( j_0 \upharpoonright \delta = j_1 \upharpoonright \delta \). For \( \xi \in S_\gamma \), let \( c_\xi = j(\delta) \) for \( j : V_\gamma \rightarrow V_\gamma \) such that \( j(\delta) = \delta \) and \( \sup j[\delta] = \xi \). Then \( c_\xi \) is ordinal definable, so \( \text{cf}^{\text{HOD}}(\xi) \leq \text{ot}(c_\xi) \). By Lemma 3.2, the HOD hypothesis holds.
As a corollary, one has the following equivalent forms of the local uniqueness of elementary embeddings at an extendible. We note that the equivalences would be quite mysterious (and hard to prove) without having the HOD hypothesis to tie them together.

**Theorem 3.5.** If \( \kappa \) is extendible, then the following are equivalent.

1. The HOD hypothesis holds.
2. For all regular \( \delta \geq \kappa \), for all sufficiently large \( \alpha \), if \( j_0, j_1 : V_\alpha \rightarrow M \) are similar at \( \delta \), then \( j_0 \upharpoonright \delta = j_1 \upharpoonright \delta \).
3. For some regular \( \delta \geq \kappa \), for all sufficiently large \( \alpha \), if \( j_0, j_1 : V_\alpha \rightarrow V_\alpha \) are similar at \( \delta \), then \( j_0 \upharpoonright \delta = j_1 \upharpoonright \delta \).
4. Let \( \nu \) be the least supercompact cardinal. For all regular \( \delta \geq \nu \), for all sufficiently large \( \alpha \), if \( j_0, j_1 : V_{\bar{\alpha}} \rightarrow V_\alpha \) are similar below \( \delta \), then \( j_0 \upharpoonright \delta = j_1 \upharpoonright \delta \).

### 3.2 \( \omega \)-Jónsson cardinals

Recall that a cardinal \( \lambda \) is \( \omega \)-Jónsson if for all functions \( f : [\lambda]^\omega \rightarrow \lambda \), there is some \( H \subseteq \lambda \) such that \( \text{ot}(H) = \lambda \) and \( \text{ran}(f \upharpoonright [H]^\omega) \) is a proper subset of \( \lambda \). The Erdos-Hajnal theorem states that assuming ZFC there is no such cardinal. One can ask what happens when one places definability constraints on \( f \).

**Definition 3.6.** A cardinal \( \lambda \) is *definably \( \omega \)-Jónsson* if for all ordinal definable functions \( f : [\lambda]^\omega \rightarrow \lambda \), there is some \( H \subseteq \lambda \) such that \( \text{ot}(H) = \lambda \) and \( \text{ran}(f \upharpoonright [H]^\omega) \) is a proper subset of \( \lambda \).

**Theorem 3.7.** Suppose \( \kappa \) is strongly compact. Then the following are equivalent:

1. The HOD hypothesis fails.
2. All sufficiently large regular cardinals are definably \( \omega \)-Jónsson.
3. Some regular cardinal above \( \kappa \) is definably \( \omega \)-Jónsson.

**Proof.** (1) implies (2). The converse rests on Solovay’s published proof of Solovay’s lemma [5]. Let \( R \) be the class of regular cardinals \( \delta \) that are not definably \( \omega \)-Jónsson. Fix \( \delta \in R \), and we will show that HOD has the \( \kappa \)-cover property below \( \delta \). This completes the proof, because assuming (2) fails, \( R \) is a proper class, and hence HOD has the \( \kappa \)-cover property, which, by Proposition 2.3, is equivalent to the HOD hypothesis given a strongly compact cardinal.

Let \( f : [\delta]^\omega \rightarrow \delta \) be an ordinal definable function such that for all \( A \subseteq \delta \) such that \( f([A]^\omega) = \delta \). We claim that any \( \omega \)-closed unbounded subset \( C \) of \( \text{sup} \ j[\delta] \) such that \( j(f)[C] \subseteq C \) contains \( j[\delta] \). Let \( B = j^{-1}[C] \). Then \( B \) is unbounded below \( \delta \) and \( B \) is closed under \( f \), and therefore \( B \supseteq f[B] = \delta \). In other words, \( j[\delta] \subseteq C \).

Working in \( M \), let \( A \) be the intersection of all \( \omega \)-closed unbounded subsets of \( \text{sup} j[\delta] \) that are closed under \( j(f) \). Then \( A \in M \) and \( j[\delta] \subseteq A \) and \( A \) is ordinal definable from \( j(f) \) in \( M \). Therefore \( A \in \text{HOD}^M \). It follows from the proof of Proposition 2.3 that HOD has the \( \kappa \)-cover property below \( \delta \).

(2) implies (3). Trivial.
Suppose $\delta \geq \kappa$ is regular and definably $\omega$-Jónsson, and assume towards a contradiction that the HOD hypothesis holds. Applying Theorem 2.10 let $(S_\alpha : \alpha < \delta) \in HOD$ partition $S^\delta_\omega$ into stationary sets. Let $f : [\delta]^\omega \to \delta$ be defined by $f(s) = \alpha$ where $\alpha < \delta$ is the unique ordinal such that $\sup(s) \in S_\alpha$. Then for any unbounded set $T \subseteq \delta$, for each $\alpha < \delta$, there is some $s \in [T]^\omega$ such that $\sup s \in S_\alpha$, and therefore $f(s) = \alpha$. It follows that $f([T]^\omega) = \delta$.

The usual characterizations of Jónsson cardinals in terms of elementary embeddings yields the following equivalence.

**Corollary 3.8.** Assume there is a strongly compact cardinal. Then exactly one of the following holds.

1. The HOD hypothesis.
2. For all sufficiently large regular cardinals $\delta$, for all ordinals $\alpha > \delta$, there is an elementary embedding $j : M \to HOD \cap V_\alpha$ such that $\text{crit}(j) < \delta$, $j(\delta) = \delta$, and $j$ is continuous at ordinals of cofinality $\omega$.

### 3.3 The rigidity of HOD

This section is devoted to a proof of the following theorem:

**Theorem 3.9.** Assume there is an $\omega_1$-strongly compact cardinal. If the HOD hypothesis holds, then there is no nontrivial elementary embedding from HOD to HOD.

We need to prove some preliminary lemmas.

**Lemma 3.10.** If $j : HOD \to HOD$ is a nontrivial elementary embedding, then $j$ has a proper class of generators.

**Lemma 3.11.** Suppose $\kappa$ is $\omega$-strongly compact and $H$ is an $\omega$-club amenable model such that arbitrarily large regular cardinals are not measurable in $H$. Then the Singular Cardinals Hypothesis holds in $H$ above $\kappa^+ \cdot (\kappa^\omega)^H$.

**Proof.** By Silver’s theorem, it suffices to show that in $H$, for all singular cardinals $\lambda > 2^{<\kappa}$ with $\text{cf}(\lambda) = \omega$, $\lambda^\omega = \lambda^+$. In fact, we will show that for all $H$-regular $\delta \geq \kappa^+$, there is a set $C \subseteq P_\kappa(\delta) \cap H$ in $H$ such that $|C|^H = \delta$ and every countable $\sigma \subseteq \delta$ is contained in some $\tau \in H$. Then in particular, $|\delta|\omega)^H \subseteq H \cup \{\sigma_\omega\}^H$ and hence $(\delta^\omega)^H = (\kappa^\omega)^H \cdot \delta$.

To define $C$, we first split $S = (S^\delta_{<\kappa})^H$ into $\delta$-many $C_{\delta,\omega}$-positive sets in $H$. Note that $S$ contains $S^\delta_\omega$ by Lemma 2.14 and hence $S$ has full measure with respect to $C_{\delta,\omega}$. Now one can use a standard argument to partition $S$ into $\delta$-many $C_{\delta,\omega}$-positive sets in $H$. Working in $H$, for each $\alpha \in S$, fix a club $c_\alpha \subseteq \alpha$ of ordertype less than $\kappa$. For $\xi < \kappa$, let $f_\xi(\alpha) = c_\alpha(\xi)$ for any such that $\xi < \text{ot}(c_\alpha)$.

We claim that there is some $\xi < \kappa$ such that for unboundedly many $\beta < \delta$, $f_\xi^{-1}(\beta)$ is $C_{\delta,\omega}$-positive. Otherwise, using that $C_{\delta,\omega}$ is weakly normal and $f_\xi$ is regressive, for each $\xi < \kappa$, there is an ordinal $\gamma_\xi$ such that $f_\xi(\alpha) < \gamma_\xi$ for an $\omega$-club of $\alpha \in S$. Since $\text{cf}(\delta) > \kappa$, there is then a single $\omega$-club of $\alpha$ such that for all $\xi < \kappa$, $f_\xi(\alpha) < \gamma_\xi$ for all appropriate $\alpha$. Letting $\gamma = \sup_{\xi < \kappa} \gamma_\xi < \delta$, we see that for an $\omega$-club of $\alpha$, for all appropriate $\xi < \kappa$, $f_\xi(\alpha) < \gamma$. But if $\alpha > \gamma$ belongs to this club, then the fact that $c_\alpha(\xi) = f_\xi(\alpha) < \gamma$ for all $\xi < \text{ot}(c_\alpha)$ contradicts that $c_\alpha$ was chosen to be unbounded in $\alpha$. 

10
Thus $k$ is bounded, which means that the class of generators of $\lambda$ satisfying $(2^\lambda)^H = \lambda^+H$ is an extender embedding. Finally, for each $\xi < \delta$ of uncountable cofinality, let $\sigma_\xi$ be the set of $\beta \in B$ such that $S_\beta$ is an extender embedding of length $\xi$. Then $\langle S_\beta : \beta \in B \rangle$ is the desired stationary partition.

Finally, for each $\xi < \delta$ of uncountable cofinality, let $\sigma_\xi$ be the set of $\beta \in B$ such that $S_\beta$ is a $\mathcal{C}_\delta,\xi$-positive. Then $\langle \sigma_\xi : \xi < \delta \rangle$ is in $H$ by $\omega$-club amenability, and the argument of Lemma 2.7 shows that every countable subset of $\delta$ is contained in $\sigma_\xi$ for some $\xi < \delta$. Therefore $C = \{\sigma_\xi : \xi < \delta\}$ is as desired. \hfill \Box

**Lemma 3.12.** Suppose $\delta$ is a cardinal, $N$ and $H$ are models with the $(\omega_1,\delta)$-cover property, and $(2^\lambda)^H = \lambda^+H$ for all sufficiently large strong limit cardinals of countable cofinality. Then any elementary embedding $k : N \to H$ with $\text{crit}(k) \geq \delta$ is an extender embedding.

**Proof.** Note that $k$ is continuous at ordinals of cofinality $\omega$, since these have $N$-cofinality less than $\delta$. We will show that there cannot exist a singular strong cardinal $\lambda$ with the following properties:

- $\text{cf}(\lambda) = \omega$.
- $\lambda$ is a limit of generators of $k$.
- $k(\lambda) = \lambda$.
- $(2^\lambda)^H = \lambda^+H$.

We first point out that $\lambda^+H = \lambda^{+N} = \lambda^+$. Using the $(\omega_1,\delta)$-cover property, $\lambda^+ \leq |P_\delta(\lambda) \cap H| \leq (2^\lambda)^H = \lambda^+H$. The argument for $N$ is similar, using that $(2^\lambda)^N = \lambda^{+N}$ by elementarity.

Let $\sigma \subseteq \lambda$ be a countable cofinal set, and let $\tau \in H$ be a cover of $\sigma$ of size less than $\delta$. Let $U$ be the $N$-ultrafilter on $P_\delta(\lambda) \cap N$ derived from $\tau$ using $\tau$. Let $j_U : N \to P$ be the ultrapower embedding and $i : P \to H$ be the factor embedding. Then $\tau = i([id]_U) \in \text{ran}(i)$, and so since $|\tau| < \delta$ and $\text{crit}(i) < \delta$, $\sigma \subseteq \text{ran}(i)$. As a consequence, $\lambda$ is a limit of generators of $j_U$, which implies $\lambda_U \geq \lambda$. But $(2^\lambda)^H = \lambda^+H$, and so by elementarity $(2^\lambda)^N = \lambda^{+N}$. Thus $\lambda_U \leq |P_\delta(\lambda) \cap N| \leq (2^\lambda)^N \leq \lambda^{+N}$. Since $\lambda \leq \lambda_U \leq \lambda^{+N}$, we must have $j_U(\lambda) > \lambda$ or $j_U(\lambda^{+N}) > \lambda^{+N}$. This implies $k(\lambda) > \lambda$ or $k(\lambda^{+N}) > \lambda^{+N}$, but contradicting either that $k(\lambda) = \lambda$ (by assumption) or that $k(\lambda^{+N}) = \lambda^+H = \lambda^{+N}$ (by the previous paragraph).

Since there is no such $\lambda$, the class of limits of generators of $k$ does not intersect the $\omega$-closed unbounded class of singular strong limit fixed points of $k$ of countable cofinality satisfying $(2^\lambda)^H = \lambda^+H$. It follows that the class of limits of generators of $k$ not closed unbounded, which means that the class of generators of $k$ is bounded, or in other words, $k$ is an extender embedding. \hfill \Box

**Lemma 3.13.** Suppose $i : H \to N$ is an extender embedding of length $\lambda$ where $\lambda$ is an $H$-cardinal of uncountable cofinality. If $H$ has the $(\omega_1,\lambda)$-cover property, then so does $N$.

**Proof of Theorem 3.12.** Suppose $j : \text{HOD} \to \text{HOD}$ is an elementary embedding and assume towards a contradiction that it is nontrivial. Let $\kappa$ be the least $\omega_1$-strongly compact cardinal. By Lemma 2.7, HOD has the $(\omega_1,\kappa)$-cover property. Let $i : \text{HOD} \to N$ be given by the extender of length $\kappa$ derived from $j$, and let $k : N \to \text{HOD}$ be the factor embedding, so $\text{crit}(k) \geq \kappa$.

By Lemma 3.13, $N$ has the $(\omega_1,\kappa)$-cover property. Lemma 3.11 implies that HOD satisfies the cardinal arithmetic condition of Lemma 3.12 and so $k$ is an extender embedding. Thus $j = k \circ i$ is an extender embedding, contradicting Lemma 3.10. \hfill \Box
4 Large cardinals in HOD

4.1 HOD under AD

Recall that a cardinal $\kappa$ is $(\nu, \delta)$-strongly compact if there is an elementary embedding $j : V \rightarrow M$ such that $\text{crit}(j) \geq \nu$ and $M$ has the $(\delta^+, j(\kappa))$-cover property. An ultrafilter $U$ witnesses that $\kappa$ is $(\nu, \delta)$-strongly compact if $\text{crit}(j_U) \geq \nu$ and $M_U$ has the $(\delta^+, j(\kappa))$-cover property. If $N$ is an inner model and $U$ is an ultrafilter, then $U$ witnesses that $\kappa$ is $\delta$-strongly compact in $N$ if $U \cap N \in N$ and $U \cap N$ witnesses that $\kappa$ is $\delta$-strongly compact in $N$.

We say an inner model $N$ has the $\kappa$-cover property below $\delta$ if $P_\kappa(\delta) \cap N$ is cofinal in $P_\kappa(\delta)$; $N$ has the $\kappa$-approximation property below $\delta$ if $N$ contains every $A \subseteq \delta$ such that $A \cap \sigma \in N$ for all $\sigma \in P_\kappa(\delta)$.

Theorem 4.1. Assume $\text{AD}^+$ and $V = L(P(\mathbb{R}))$. Suppose $\kappa < \Theta$ is a regular cardinal and $\delta \geq \kappa$ is a HOD-regular ordinal. Then the following are equivalent:

1. $(S^\delta_{<\kappa})^\text{HOD}$ is stationary.
2. HOD has the $\kappa$-cover property below $\delta$.
3. HOD has the $\kappa$-cover and $\kappa$-approximation properties below $\delta$.
4. $C_{\delta, \omega}$ witnesses that $\kappa$ is $\delta$-strongly compact in HOD.
5. Some countably complete ultrafilter witnesses $\kappa$ is $(\omega_1, \delta)$-strongly compact in HOD.
6. HOD has the $\omega_1, \kappa)$-cover property below $\delta$.
7. $S^\delta_\kappa \subseteq (S^\delta_{<\kappa})^\text{HOD}$.

Proof. (1) implies (2) Let $T = (S^\delta_{<\kappa})^\text{HOD}$. We claim that $S^\delta_\kappa \cap T$ is stationary. Fix a sequence $\langle c_\alpha : \alpha \in T \rangle \in \text{HOD}$ such that $c_\alpha$ is a closed cofinal subset of $\alpha$ of ordertype $\text{cf}(\text{HOD}(\alpha))$. Let $S = \{ \beta \in S^\delta_\kappa : \exists \alpha \in T \sup(c_\alpha \cap \beta) = \beta \}$.

Suppose $C$ is closed unbounded, and we will show $C \cap S \neq \emptyset$. Since $T$ is stationary, there is some $\beta$ in $\text{acc}(C)$ such that $\sup(c_\alpha \cap \beta) = \beta$. We claim that the least such $\beta$ has countable cofinality. If not, then $\beta$ has uncountable cofinality, so $C \cap c_\beta \cap \beta$ is closed unbounded. But fixing any $\beta' \in \text{acc}(C \cap c_\beta \cap \beta)$, we have $\beta' \in \text{acc}(C)$ and $\sup(c_\alpha \cap \beta') = \beta'$, contrary to the minimality of $\beta$.

Next, we construct a sequence $\langle \sigma_\xi : \xi \in T \rangle$ such that $\sigma_\xi \in P_\kappa(\xi)$ and for all $\alpha$, for $C_{\delta, \omega}$-almost all $\xi$, $\alpha \in \sigma_\xi$. This proceeds as in Theorem 2.3 using however that $C_{\delta, \omega}$ is an ultrafilter. As in Theorem 2.3, one can use this sequence to show $\text{cf}(\delta) = |\delta|$. Let $C \subseteq \delta$ be a closed cofinal set of ordertype $\text{cf}(\delta)$. Then $\delta = \bigcup_{\xi \in C} \sigma_\xi$. Therefore $|\delta| = |C| \cdot \sup_{\xi \in C} |\sigma_\xi|$, so as in Theorem 2.3 $|\delta| = |C| \cdot |\text{cf}(\delta)|$.

Finally, suppose $\sigma \in P_\kappa(\delta)$. The set $\{ \xi \in T : \sigma \subseteq \sigma_\xi \}$ is the intersection of fewer than $\kappa$-many sets in $C_{\delta, \omega}$, and so it belongs to $C_{\delta, \omega}$. It follows that there is some $\xi \in T$ such that $\sigma \subseteq \sigma_\xi$. This shows that HOD has the $\kappa$-cover property below $\delta$.

(2) implies (3) In HOD, let $\langle X_\alpha : \alpha < \delta \rangle$ be a $\kappa$-independent family of subsets of some set $S$. Suppose $A \subseteq \delta$ and $A \cap \sigma \in \text{HOD}$ for all $\sigma \in P_\kappa(\delta) \cap \text{HOD}$. For $\alpha < \delta$, let

$$Y_\alpha = \begin{cases} X_\alpha & \text{if } \alpha \in A \\ S \setminus X_\alpha & \text{otherwise} \end{cases}$$
Suppose $\sigma \subseteq \delta$ are disjoint. We will show that $\bigcap_{\alpha \in \sigma} Y_\alpha \neq \emptyset$. First, let $\tau \in \text{HOD}$ cover $\sigma$. Then by our assumption on $A$, $\tau \cap A \in \text{HOD}$. It follows that $(Y_\alpha : \alpha < \delta)$ is $\kappa$-independent in $\text{HOD}$, and therefore since $(X_\alpha : \alpha < \delta)$ is $\kappa$-independent in $\text{HOD}$, $\bigcap_{\alpha \in \tau} Y_\alpha \neq \emptyset$. Since $\sigma \subseteq \tau$, $\bigcap_{\alpha \in \sigma} Y_\alpha \neq \emptyset$. Let $F$ be the filter generated by $\{Y_\alpha : \alpha < \delta\}$. Then $F$ is a $\kappa$-complete filter on a wellorderable set, and so $F$ extends to a countably complete ultrafilter $U$. Applying AD, $U \cap \text{HOD} \subseteq \text{HOD}$, and therefore $A = \{\alpha < \delta : X_\alpha \in U\}$ belongs to $\text{HOD}$ as well.

(6) implies (7). Trivial.

(7) implies (6). Let $U$ be a countably complete ultrafilter on $\delta$ such that $U \cap \text{HOD}$ witnesses that $\kappa$ is $\langle \omega_1, \delta \rangle$-strongly compact in $\text{HOD}$. Let $f : \delta \to P_\kappa(\delta) \cap \text{HOD}$ push $U \cap \text{HOD}$ forward to a fine ultrafilter in $\text{HOD}$. Let $U = f^*(U)$. Then $U$ is a fine countably complete ultrafilter, and therefore for all $\sigma \in P_{\omega_1}(\delta)$, the set $\{\tau \in P_\kappa(\delta) : \sigma \subseteq \tau\}$ belongs to $U$. Since $P_\kappa(\delta) \cap \text{HOD} \subseteq U$, it follows that there is some $\tau \in P_\kappa(\delta) \cap \text{HOD}$ such that $\sigma \subseteq \tau$. This shows that $\text{HOD}$ has the $\langle \omega_1, \delta \rangle$-cover property.

(6) implies (7). Trivial.

(7) implies (6). Trivial. □

In the context of $\text{AD}^+ + V = L(P(\mathbb{R}))$, Woodin’s $\text{HOD}$-ultrafilter conjecture asserts that every countably complete ultrafilter of $\text{HOD} \cap V_\Theta$ extends to a countably complete ultrafilter.

**Theorem 4.2.** Assume $\text{AD}^+, V = L(P(\mathbb{R}))$, and the $\text{HOD}$-ultrafilter conjecture. Suppose $\kappa < \Theta$ is a regular cardinal and $\delta \geq \kappa$ is a $\text{HOD}$-regular ordinal. Then $\kappa$ is $\delta$-strongly compact in $\text{HOD}$ if and only if $\kappa$ is $\langle \omega_1, \delta \rangle$-strongly compact in $\text{HOD}$. □

### 4.2 Weak extender models

**Definition 4.3.** If $U$ is a $\kappa$-complete ultrafilter on $\lambda$ and $\sigma \in P_\kappa(P(\lambda))$, then $A_U(\sigma) = \bigcap_{\alpha \in \sigma} A$ and $\chi_U(\sigma) = \min A_U$. Suppose $F$ is a filter on $P_\kappa(P(\lambda))$ and $U, W$ are $\kappa$-complete ultrafilters on $\lambda$. Then $U <_F W$ if $\chi_U(\sigma) < \chi_W(\sigma)$ for $F$-almost all $\sigma \in P_\kappa(P(\lambda))$.

**Lemma 4.4.** Suppose $F$ is a filter on $P_\kappa(P(\lambda))$. Then $<_F$ is a strict partial order. If $F$ is countably complete, then $<_F$ is wellfounded. If $F$ is an ultrafilter, then $<_F$ is linear.

Thus $<_F$ is a wellorder if $F$ is a countably complete ultrafilter on $P_\kappa(P(\lambda))$. The Ultrapower Axiom, which we will not discuss here, implies that if $F$ is the closed unbounded filter on $P_{\omega_1}(P(\lambda))$, then $<_F$ is a wellorder. This is also a consequence of $\text{AD}_\mathbb{R}$ if $\lambda < \Theta$.

We will use the order $<_F$ in the proof of the following theorem.

**Theorem 4.5.** Suppose $\kappa$ is strongly compact and $N$ is an inner model of ZFC with the $\kappa$-cover property. Then there is a minimum extension of $M$ to a model of ZFC with the $\kappa$-approximation property. The proof uses the following lemmas.

**Lemma 4.6.** Suppose $\delta$ is a regular cardinal, $\kappa$ is $\delta$-strongly compact, $N$ is an inner model of ZFC with the $\kappa$-cover property, and $M$ is an inner model containing $N$ such that every $\kappa$-complete $N$-ultrafilter on $\delta$ belongs to $M$. Then every subset of $\delta$ that is $\kappa$-approximated by $N$ belongs to $M$. □
Theorem 4.7 (Hamkins). Suppose \( \kappa < \lambda \) are cardinals, \( \text{cf}(\lambda) \geq \kappa \) and \( M \) and \( M' \) are inner models with the \( \kappa \)-approximation and cover properties below \( \lambda \) such that \( P_\kappa(\kappa^+) \cap M = P_\kappa(\kappa^+) \cap M' \). Then \( P_{bd}(\lambda) \cap M = P_{bd}(\lambda) \cap M' \). \( \square \)

**Proof of Theorem 4.7.** Suppose \( \mathcal{U} \) is a \( \kappa \)-complete fine ultrafilter on \( P_\kappa(\lambda) \) where \( \lambda \) is a strong limit cardinal \( \lambda \) of cofinality at least \( \kappa \) and \( P_\kappa(\lambda) \cap N \in \mathcal{U} \). Suppose \( f : \lambda \to P_{bd}(\lambda) \cap N \) is a surjection in \( N \). Let \( \mathcal{U} \) denote the pushforward of \( \mathcal{U} \) by the function \( f : P_\kappa(\lambda) \rightarrow P_\kappa(P_{bd}(\lambda)) \) given by \( f[\sigma] = f[\sigma] \). Let \( \tilde{U} = \mathcal{U}_{\Upsilon, f} = \langle U_\alpha : \alpha < \lambda \rangle \) enumerate the \( \kappa \)-complete \( N \)-ultrafilters on ordinals less than \( \lambda \) in the wellorder \( \Upsilon \). Let \( N' \) be the inner model \( L[\tilde{U}, f] \) and let \( f' \) be the increasing enumeration of \( P_{bd}(\lambda) \cap N' \) in the following order: for \( a, b \in P_{bd}(\lambda) \cap N' \), set \( a < b \) if either \( \text{sup}(a) < \text{sup}(b) \) or \( a \) precedes \( b \) in the canonical wellorder of \( L[\tilde{U}, f] \) and \( \text{sup}(a) = \text{sup}(b) \).

Note that any model \( M \) with the \( \kappa \)-approximation property that contains \( N \) must contain the set of \( \kappa \)-complete \( N \)-ultrafilters on ordinals less than \( \lambda \) and the order on it induced by \( \mathcal{U} \). Hence \( N' \subseteq M \).

Iterating this procedure yields, for each ordinal \( \gamma \), an inner model \( N_\gamma = N_{\Upsilon, f, \gamma} \) of ZFC, a function \( f_\gamma \), and a \( \lambda \)-sequence \( \tilde{U}_\gamma \) enumerating the \( \kappa \)-complete \( N_\gamma \)-ultrafilters on ordinals less than \( \lambda \). Specifically (although still somewhat informally), let \( N_\gamma = L[\tilde{U}_\xi, f_\xi : \xi < \gamma] \), let \( f_\gamma : \lambda \to P_{bd}(\lambda) \cap N_\gamma \) be the increasing enumeration of \( P_{bd}(\lambda) \cap N_\gamma \) in a wellorder similar to the one described in the first paragraph, and finally define \( \tilde{U}_\gamma = \mathcal{U}_{\Upsilon, f_\gamma} \) as in the first paragraph.

The uniformity of this procedure guarantees that any model \( M \) such that \( N \subseteq M \) and \( \mathcal{U} \cap M \subseteq M \) contains \( N_\gamma \) for all ordinals \( \gamma \).

The sequence \( \langle N_\gamma : \gamma < \kappa^+ \rangle \) is increasing, so let \( \gamma = \gamma_{\Upsilon, f} \) be the least ordinal \( \alpha < \kappa^+ \) such that \( N_\alpha \cap P_{bd}(\kappa) = N_{\alpha+1} \cap P_{bd}(\kappa) \). We claim that \( N_{\gamma+1} \) has the \( \kappa \)-approximation property below \( \lambda \).

Notice that \( P_\kappa(\lambda) \cap N_\gamma = P_\kappa(\lambda) \cap N_{\gamma+1} \): if \( \sigma \in P_\kappa(\lambda) \cap N_{\gamma+1} \), then there is some \( \tau \in P_\kappa(\lambda) \cap N \) such that \( \sigma \subseteq \tau \); then \( \sigma \in N_\gamma \) and hence \( P_{bd}(\kappa) \cap N_\gamma = P_{bd}(\kappa) \cap N_{\gamma+1} \) because \( \Upsilon \subseteq N \), \( P(\tau) \cap N_\gamma = P(\tau) \cap N_{\gamma+1} \); the latter set contains \( \sigma \), and hence \( \sigma \in N_\gamma \) as desired. Lemma 4.6 and the definition of \( N_{\gamma+1} \), every bounded subset of \( \lambda \) that is \( \kappa \)-approximated by \( N_\gamma \) belongs to \( N_{\gamma+1} \). Since \( P_\kappa(\lambda) \cap N_\gamma = P_\kappa(\lambda) \cap N_{\gamma+1} \), every subset of \( \lambda \) that is \( \kappa \)-approximated by \( N_{\gamma+1} \) is \( \kappa \)-approximated by \( N_{\gamma+1} \). Thus \( N_{\gamma+1} \) has the \( \kappa \)-approximation property below \( \lambda \).

Now for each pair \( (\mathcal{U}, f) \) such that there is a strong limit cardinal \( \lambda \) of cofinality at least \( \kappa \) such that \( \mathcal{U} \) is a \( \kappa \)-complete fine ultrafilters on \( P_\kappa(\lambda) \) and \( f : \lambda \to P_{bd}(\lambda) \) is a surjection in \( N \), let \( M_{\Upsilon, f} = N_{\Upsilon, f, \gamma} \cap H(\lambda) \), where \( \gamma = \gamma_{\Upsilon, f} \). Reiterating what we have proved above, any inner model \( M \) of ZFC such that \( N \subseteq M \) and \( \mathcal{U} \cap M \subseteq M \) must contain \( M_{\Upsilon, f} \), and therefore any inner model \( M \) of ZFC with the \( \kappa \)-approximation property contains \( \bigcup_{\Upsilon, f} M_{\Upsilon, f} \).

Fix \( S \subseteq P_\kappa(\kappa^+) \) such that for a proper class of appropriate \( \mathcal{U} \) and \( f \), \( M_{\Upsilon, f} \cap P_\kappa(\kappa^+) = S \). Let \( C \) be the class of pairs \((\mathcal{U}, f)\) such that \( M_{\Upsilon, f} \cap P_\kappa(\kappa^+) = S \). Then by the Hamkins uniqueness theorem (Theorem 4.4), for all \( u, v \in C \), either \( M_u \subseteq M_v \) or \( M_v \subseteq M_u \). Thus \( M = \bigcup_{u \in C} M_u \) is an inner model of ZFC, and since each \( M_u \) has the \( \kappa \)-approximation property below \( \lambda \), \( M \) has the \( \kappa \)-approximation property. Finally, \( N \subseteq M \) since for all but a set of \( u \in C \), \( N \cap H(\lambda) \subseteq M_u \). \( \square \)

The construction of the previous theorem is much simpler when \( N \) is an inner model that not only has the \( \kappa \)-cover property (i.e., is positive for the fine filter) but also is positive for the supercompactness filters \( N_{\kappa, \lambda} \), defined for all \( \kappa \leq \lambda \) as the intersection of the \( \kappa \)-complete normal fine ultrafilters on \( P_\kappa(\lambda) \).
Definition 4.8. An inner model $N$ is $(\kappa, \lambda)$-supercompact if $N \cap P_\kappa(\lambda)$ is $N_{\kappa, \lambda}$-positive; $N$ is $(\kappa, \infty)$-supercompact if it is $(\kappa, \lambda)$-supercompact for all cardinals $\lambda$.

Note that $N$ is $(\kappa, \lambda)$-supercompact if and only if $N \cap P_\kappa(\lambda)$ belongs to some $\kappa$-complete normal fine ultrafilter on $P_\kappa(\lambda)$, and if $N$ is $(\kappa, \lambda)$-supercompact for some ordinal $\lambda$, then $N$ is $(\kappa, \alpha)$-supercompact for all $\alpha < \lambda$. The notion bears an obvious resemblance to Woodin’s weak extender models.

Definition 4.9. An inner model $N$ of ZFC is a weak extender model of $\kappa$ is $\lambda$-supercompact if there is a $\kappa$-complete normal fine ultrafilter $U$ on $P_\kappa(\lambda)$ such that $U \cap N \in N$ and $P_\kappa(\lambda) \cap N \in U$; $N$ is a weak extender model of $\kappa$ is supercompact if it is a weak extender model of $\kappa$ is $\lambda$-supercompact for all cardinals $\lambda$.

The substantive part of the following characterization of weak extender models is due to Woodin and Usuba independently.

Lemma 4.10. An inner model of ZFC is a weak extender model of $\kappa$ is supercompact if and only if it is $(\kappa, \infty)$-supercompact and has the $\kappa$-approximation property.

The following theorem shows that the $(\kappa, \infty)$-supercompact inner models are precisely the $<\kappa$-closed inner models of weak extender models.

Theorem 4.11. If $N$ is a $(\kappa, \infty)$-supercompact inner model of ZFC, then there is a weak extender model of $\kappa$ is supercompact that contains $N$ as a $<\kappa$-closed inner model.

Proof. The reverse direction is obvious, so we focus on the forwards direction. Let $\lambda$ be a cardinal and let $U$ be a $\kappa$-complete normal fine ultrafilter on $P_\kappa(\lambda)$ such that $P_\kappa(\lambda) \cap N \in N$, and let $j : V \to M$ be the associated ultrapower embedding. Let $W = j(N)$. We claim $W$ contains every subset $A$ of $\lambda$ that is $\kappa$-approximated by $N$.

To see this, note that since $W$ has the $j(\kappa)$-cover property in $M$, we can find $\sigma \in P_{j(\kappa)}(j(\lambda))$ such that $j(A) \subseteq \sigma$. But $j(A)$ is $j(\kappa)$-approximated by $W$, so $j(A) \cap \sigma \in W$. Since $P_\kappa(\lambda) \cap N \in U$, $j(\lambda) \in W$, and this implies $A = j^{-1}[j(A) \cap \sigma] \in W$, as desired.

Next, a familiar argument shows that since $N \cap P(\lambda) \subseteq W$, $N \cap V_\kappa = W \cap V_\kappa$, and $N$ has the $\kappa$-cover property, in fact, $P_\kappa(\lambda) \cap W \subseteq N$. This implies that $W$ has the $\kappa$-approximation property below $\lambda$.

It follows that for any $\kappa$-complete normal fine ultrafilters $U$ and $U'$ with $P_\kappa(\lambda) \cap N \in U \cup U'$, $j_U(N) \cap P(\lambda) = j_{U'}(N) \cap P(\lambda)$ by the preceding remarks and the Hamkins uniqueness theorem. Letting $X$ be the union of $j_U(N) \cap P(\lambda)$ for all $U$ such that $P_\kappa(\lambda) \cap N \in U$, it follows that $M = L(X)$ is a model of ZFC with the $\kappa$-approximation and cover properties and $N$ is a $<\kappa$-closed inner model of $M$. Since $N$ is $(\kappa, \infty)$-supercompact and $M$ has the $\kappa$-approximation property, Lemma 4.10 implies that $N$ is a weak extender model of $\kappa$ is supercompact.

A cardinal $\kappa$ is distributively supercompact if for all cardinals $\lambda$, there is a $\kappa$-distributive partial order $P$ such that $\kappa$ is $\lambda$-supercompact in $V^P$.

Corollary 4.12 (HOD Hypothesis). Suppose $\kappa$ is supercompact. Then there is a unique weak extender model of $\kappa$ is supercompact that contains HOD as a $<\kappa$-closed inner model. In particular, HOD satisfies that $\kappa$ is distributively supercompact.
The following corollary shows that the first-order theory of HOD has an influence on the question of whether the least supercompact cardinal is supercompact in HOD. One could actually replace UA in the argument with any \( \Pi_2 \) sentence that implies that every countably complete ultrafilter on an ordinal is ordinal definable.

**Theorem 4.13.** Suppose \( \kappa \) is a supercompact cardinal and the HOD hypothesis holds. If \( V_\kappa \cap \text{HOD} \) satisfies the Ultrapower Axiom, then \( \kappa \) is supercompact in HOD.

**Proof.** Let \( N \) be the inner model of Corollary 4.12. Then \( N \) is definable without parameters and \( V_\kappa \cap \text{HOD} = V_\kappa \cap N \preceq \Sigma_2 N \) since \( \kappa \) is supercompact in \( N \). Since UA is \( \Pi_2 \), \( N \) satisfies UA. Now working in \( N \), we apply the following consequence of UA: if \( \kappa \) is supercompact and \( A \) is a set such that \( V_\kappa \subseteq \text{HOD}_A \), then \( V = \text{HOD}_A \). Therefore \( N = (\text{HOD}_A)^N \) for any set of ordinals \( A \in N \) such that \( V_\kappa \cap N \subseteq (\text{HOD}_A)^N \). Let \( A \in \text{HOD} \) be a set of ordinals such that \( V_\kappa \cap \text{HOD} \subseteq L[A] \). Then \( A \in N \) and \( N = (\text{HOD}_A)^N \), so there is a wellorder of \( N \) definable over \( N \) from \( A \). Since \( N \) is definable without parameters and \( A \) is ordinal definable, this wellorder of \( N \) is definable from an ordinal parameter. Any ordinal definably wellordered transitive class is contained in HOD, so \( N \subseteq \text{HOD} \). Therefore \( \text{HOD} = N \), and so \( \kappa \) is supercompact in HOD. \( \square \)
