Disturbed expression of microRNAs (miRNAs) in regulatory T cells (Tregs) leads to development of autoimmunity in experimental mouse models. However, the miRNA expression signature characterizing Tregs of autoimmune diseases, such as rheumatoid arthritis (RA) has not been determined yet. In this study, we have used a microarray approach to comprehensively analyze miRNA expression signatures of both naive Tregs (CD4+CD45RO–CD25+++) and memory Tregs (CD4+CD45RO+CD25+++) as well as conventional naive (CD4+CD45RO–CD25–) and memory (CD4+CD45RO+CD25–) T cells (Tconvs) derived from peripheral blood of RA patients and matched healthy controls. Differential expression of selected miRNAs was validated by TaqMan-based quantitative reverse transcription-PCR. We found a positive correlation between increased expression of miR-451 in T cells of RA patients and disease activity score (DAS28), erythrocyte sedimentation rate levels and serum levels of interleukin-6. Moreover, we found characteristic, disease- and treatment-independent, global miRNA expression signatures defining naive Tregs, memory Tregs, naive Tconvs and memory Tconvs. The analysis allowed us to define miRNAs characteristic for a general naive phenotype (for example, miR-92a) and a general memory phenotype (for example, miR-21, miR-155). Importantly, the analysis allowed us to define miRNAs that are specifically expressed in both naive and memory Tregs, defining as such miRNA signature characterizing the Treg phenotype (that is, miR-146a, miR-3162, miR-1202, miR-1246 and miR-4281).

**Keywords:** Treg; miRNA; naive; memory; rheumatoid arthritis

INTRODUCTION

Rheumatoid arthritis (RA) is an autoimmune disease characterized by chronic inflammation of synovial tissue that leads to damage of cartilage and bone, resulting in irreversible joint destruction. A number of genetic factors associated with RA suggest that deviant regulation of T cells might have an important role in the development and course of the disease.1-3 Moreover, despite the large numbers of regulatory T cells (Tregs) present in the synovial fluid of RA patients4-6 and despite the treatment, the inflammatory state of the joint persists. This suggests a potential functional defect in the Treg compartment or the resistance of effector T cells to Treg-mediated suppression.7

Tregs maintain immune homeostasis through suppression of excessive lymphocyte proliferation and cytokine production.8 Several studies have indicated that Tregs isolated from RA patients are functionally compromised and fail to suppress production of pro-inflammatory cytokines such as interleukin (IL)-17, interferon-γ and tumor necrosis factor (TNF-α).9-11 Defective function of RA Tregs has been associated with exposure to elevated levels of pro-inflammatory cytokines in the synovial fluid of the inflamed joints. TNF-α, by itself, was shown to affect the transcriptional profile of protein-coding genes and the level of Foxp3 phosphorylation, leading to decreased suppressive function of Tregs.12,13 In addition, increased TNF-α levels detected in synovial fluid of RA patients correlated positively with the deviant expression of microRNAs (miRNAs) in T cells,14 indicating that the pro-inflammatory cytokines affect T cells also at the post-transcriptional level.

MiRNAs are a class of small, 20–22 nucleotide long, noncoding RNA species that regulate gene expression at the post-transcriptional level. After loading into the RNA-induced silencing complex, miRNAs prevent translation or promote degradation of target mRNA by homologous binding to the 3′-untranslated region.15 Thus, miRNAs regulate protein expression and allow intricate fine tuning of cell biological processes. Over the last decade it has become clear that miRNAs regulate the expression of genes in fundamental biological processes related to development, proliferation16 and apoptosis18 as well as pathological processes such as cancer and autoimmunity.19-21 The decisive impact of miRNAs, on the functioning and lineage stability of T-cell subsets, including Tregs, has been reported in a number of mouse studies.22-25 Indeed, disruption of normal miRNA biogenesis in Tregs leads to breakdown of tolerance and shifts in the lineage specificity of Tregs in experimental model systems.24 A number of studies have recently shown differential expression of specific miRNAs in peripheral blood mononuclear cells, T-cells and tissues of human inflammatory diseases, including systemic lupus erythematosus and RA.13,25-28 However, the miRNA expression of peripheral blood Tregs and conventional T cells (Tconvs) of RA

patients has not been reported yet. Miyara et al.²⁹ have recently showed that, similar to Tconvs, Tregs can be subclassified into interrelated naive Tregs (that is, resting Tregs) and memory Tregs (that is, activated Tregs), with both overlapping and distinct phenotypic and functional characteristics. Importantly, such classification allows a precise delineation of Treg subpopulations and enables their efficient isolation.³⁰

In this study, we set out to comprehensively analyze miRNA expression signatures of four functionally relevant and distinct CD4⁺ T-cell subsets (that is, naive Tregs, memory Tregs, naive Tconvs and memory Tconvs) derived from RA patients, before and after anti-TNF-α treatment, and from healthy donors. The global T-cell subset-specific miRNA expression patterns were not altered by either the disease state or the type of treatment received by RA patients. However, the expression of miR-451 correlated positively with the RA disease activity score (DAS28). Furthermore, the analysis of the defined T-cell subsets provided characteristic expression signatures of both naive and memory Treg and Tconv subsets.

RESULTS

The global T-cell subset-specific miRNA expression patterns are not affected by RA or anti-inflammatory treatment

The miRNA signature of Tregs in RA was studied using a cohort of 27 RA patients fulfilling the 1987 ACR criteria for the classification of RA and six healthy controls (HC). The characteristics of all donors are summarized in Table 1. Possible confounding effects of disease modifying anti-inflammatory drugs on T cells were accounted for by including patients before and after the start of treatment with disease modifying anti-inflammatory drugs. Patients were further subdivided according to the type of treatment into two groups, that is, patients treated with methotrexate (MTX) alone, and patients treated with MTX and Adalimumab, an anti-TNF-α monoclonal antibody. CD4⁺ Tregs and Tconvs were isolated using the gating strategy devised by Miyara et al.²⁹ which allows subclassification of T cells into naive Tregs (CD45RO⁻ CD25⁺ Foxp3⁺), memory Tregs (CD45RO⁺ CD25⁻ Foxp3⁺), naive Tconvs (CD45RO⁻ CD25⁻ Foxp3⁻) and memory Tconvs (CD45RO⁺ CD25⁻ Foxp3⁻), as depicted in Figure 1a. Differential expression of Foxp3 was assessed by fluorescence-activated cell sorting staining (Figure 1b) and confirmed in the sorted T-cell subsets by quantitative reverse transcription (qRT)-PCR (Figure 1c). The percentage of naive and memory Tregs, the expression level of Foxp3 transcript as well as the percentage and numbers of monocytes, natural killer cells, total T and B cells did not differ between HC and RA patient groups (Supplementary Figures 1A and B, and data not shown). The global miRNA expression patterns were determined in 24 subsets of six RA patients and in 8 subsets of two HC (Table 1, array) using the Agilent Human miRNA Microarray (Agilent

IL-6 has been shown to induce expression of miR-451 in dendritic cells, and serum levels of IL-6 (Figure 3e), indicating that the inflammatory response is positively correlated between the miR-451 expression in T cells and the measured IL-6 levels in the sera of RA patients. Indeed, we found a statistically significant positive association between the expression of miR-451 and the presence of IL-6, which may be related to an increased presence of IL-6 in T cells. To identify specific miRNAs that were differentially expressed as a result of disease characteristics or the type of treatment, we performed an unsupervised hierarchical clustering of all samples. Clustering separated the samples, with one exception, into four phenotypic groups (naïve Tconv, memory Tconv, memory Treg and naïve Treg), irrespective of the disease or type of treatment, indicating that each T-cell subset is characterized by a very specific miRNA signature. No further biologically meaningful clustering pattern was observed. This indicates that the global miRNA expression patterns characterizing T-cell subsets are not affected by the disease or the anti-inflammatory treatment (Figures 2a and b).

Expression of miR-451 in T cells positively correlates with the DAS28

To identify specific miRNAs that were differentially expressed as a result of disease characteristics or treatment, we performed an intergroup statistical analysis. From this analysis, miR-451 was identified to be significantly higher expressed in patients treated with MTX (RA MTX, fold difference ≥ 2, corrected P-value < 0.05), irrespective of the T-cell subset (Figure 3a). Surprisingly, qRT–PCR analysis performed in a new cohort of 10 RA patients and 4 HC (Table 1, qRT–PCR validation) identified miR-451 to be significantly higher expressed in a group of newly diagnosed, disease-modifying anti-rheumatic drug-free RA patients (RA new; Figure 3b). This discrepancy prompted us to investigate whether the expression of miR-451 in T cells is related to the disease characteristics of individual patients in the cohorts included in the study. Indeed, analysis of 27 patients revealed that the expression of miR-451 correlated positively with DAS28 and, more specifically, with the erythrocyte sedimentation rate (ESR; Figures 3c and d). Correlations with anti-cyclic citrullinated peptide antibodies, rheumatoid factor level or age were not found (data not shown). Both DAS28 score and ESR have been previously correlated with the serum levels of pro-inflammatory cytokine IL-6.31 Moreover, IL-6 has been shown to induce expression of miR-451 in dendritic cells.32 To test whether an increased expression of miR-451 in T cells could be related to an increased presence of IL-6, we measured IL-6 levels in the sera of RA patients. Indeed, we found a positive correlation between the miR-451 expression in T cells and serum levels of IL-6 (Figure 3e), indicating that the inflammatory status of RA patients, resulting from an active disease, may be responsible for the observed increased expression of miR-451.

Naive and memory Treg subsets are characterized by distinct miRNA signatures

Unsupervised clustering separated both Treg and Tconv samples into either a naïve or a memory phenotype, which was irrespective of disease characteristics or the type of treatment (Figure 2). To determine which miRNAs in particular were responsible for this clustering pattern, we performed statistical analysis between the four T-cell subsets across all eight donors. This resulted in the identification of 42 significantly differently expressed human miRNAs (Table 2, fold change ≥ 2, corrected P-value < 0.005). Two-way unsupervised hierarchical clustering revealed four distinct miRNA clusters (I–IV) separating the samples into four cellular phenotypes (Figure 4a, and Table 2). MiRNAs defined in cluster I were overrepresented in naive Tcells and underrepresented in memory Tregs. MiRNAs defined in cluster II were overrepresented in naive T cells irrespective of CD25 expression. MiRNAs defined in cluster III were overrepresented in Tregs irrespective of naive or memory phenotype. MiRNAs defined in cluster IV were overrepresented in memory T cells irrespective of CD25 expression (Figure 4a). To validate these findings, we selected nine miRNAs, two to three from each cluster, based on their high expression and/or high-fold difference between T-cell subsets, and based on the literature reporting involvement of a given miRNA in the T-cell biology23,33–35 (Table 2, in bold), and we assessed their expression in a new group of 14 donors (Table 1, qRT–PCR validation). Expression patterns of miR-29c, miR-363, miR-31, miR-92a, miR-146a, miR-1246, miR-21 and miR-24 were consistent with the array data (Figure 4b), whereas the expression of miR-320d could not be determined owing to the lack of specificity of the primers/probe pair.

To better visualize the overlap between miRNA signatures defining each of the four T-cell subsets, we made a Venn diagram based on high expression levels of the significantly differentially expressed miRNAs in each of the subsets, as defined by the percentages given in Table 2 (Figure 5). In the Tconv subset, 16 miRNAs showed a consistent high expression in both naïve and memory phenotypes, of which 9 were also high in naïve Tregs and 4 were also high in memory Tregs. Three miRNAs were highly expressed specifically in the memory Tconvs and six miRNAs were highly expressed specifically in naïve Tconvs. In the Treg subset,
five miRNAs, that is, miR-146a, miR-3162, miR-1202, miR-1246 and miR-4281, showed a consistent high expression irrespective of the naive or memory phenotype. Nine memory Treg-specific miRNAs were also highly expressed in the memory Tconvs, and therefore should be regarded as miRNAs that define a general memory phenotype. Similarly, the three naive Treg-specific miRNAs were...
also highly expressed in the naive Tconvs, and as such should be regarded as miRNAs defining a general naive phenotype. Thus, the differential expression of miRNAs between naive and memory Treg subsets is partly a consequence of their respective naive and memory phenotypes. Together, these data show that some miRNAs show an abundant expression confined to Tregs irrespective of their maturation stage (for example, miR-146a and miR-1246), whereas several miRNAs previously linked to the Treg phenotype (for example, miR-21 and miR-155) are in fact specifically confined to a memory T-cell phenotype.

DISCUSSION

Many studies, mostly in experimental models, have shown the critical involvement of miRNAs in the maintenance of Treg lineage stability and function.21,24 Recently, Miyara et al.29 fueled the notion of further complexity in the Treg compartment and underlined the necessity to consider naive and memory Tregs as separate regulatory entities. In this study, we performed a comprehensive analysis of the miRNA expression profiles of naive Tregs, memory Tregs, naive Tconvs and memory Tconvs in RA patients and HC. We found characteristic, disease- and treatment-independent, global miRNA expression signatures allowing a clear, miRNA-based subclassification of T-cell subsets into naive Tconv, naive Treg and memory-like phenotypes. In addition, we found that the expression of miR-451 in T cells is associated with DAS28, ESR and serum levels of IL-6.

Several reports have shown the critical involvement of miRNAs in the maintenance of Treg lineage stability and function. The work of Liston et al.,21 Zhou et al.24 and Cobb et al.36 clearly demonstrates that disturbed expression of miRNAs leads to serious and complex alterations in Treg function, resulting in the development of systemic autoimmune-like conditions in mice. MiRNA expression signatures characterizing Tregs of both mice and man have been described.33,36–38 However, the gating strategies employed so far, based on the CD25high expression, did not include a memory marker and as such did not separate naive and memory Treg populations. In this study we used a recently described gating strategy,29 and we show that human naive and memory Tregs are characterized by distinct miRNA expression signatures. Our data clearly show that several miRNAs previously linked to the Treg phenotype (that is, miR-21, miR-22, miR-24 and miR-155)23,33,38 are differentially expressed between naive and memory Tregs, and are specifically confined to a memory T-cell phenotype. Especially intriguing, in this respect, is the role of miR-155, which has been shown to provide a ‘competitive fitness’ to Tregs in mice.22 Differential expression of miR-155 between naive and memory Tregs has recently been reported in a study by Seddiki et al.39 which is consistent with our data. Importantly, we found that five miRNAs (miR-146a, miR-3162,

Abbreviations: miRNA, microRNA; Tconv, conventional T cell; Tregs, regulatory T cell. Bold values indicate *P* < 0.05.
miR-1202, miR-1246 and miR-4281) were significantly enriched in both naive and memory Tregs, indicating their involvement in the maintenance of a specific Treg phenotype, whereas three miRNAs were significantly under-represented in both Treg subsets (miR-142-5p, let-7c and miR-590-5p). Of the miRNAs enriched in Tregs, miR-146a stands out because of its abundant expression level. MiR-146a is known for its involvement in innate immunity where it has been shown to inhibit myeloid cell proliferation and oncogenesis. In adaptive immunity, miR-146a has been reported to control TCR signaling via negative regulation of NF-κB as well as to impair IL-2 production and to protect T cells from antigen-induced cell death. Interestingly, miR-146a is induced upon T-cell activation and its elevated expression has been previously linked to the memory T-cell phenotype. Indeed, we found increased miR-146a levels in memory Tconvs compared with naive Tconvs. Notably, miR-146a expression has been studied

Figure 4. MiRNA signatures characterizing T-cell subsets. (a) Heatmap (Pearson's correlation, median centering miRNAs, complete linkage) showing the miRNA expression signatures that characterize Tconvs and Tregs in 32 samples derived from six RA patients and two healthy controls, using miRNA microarray. Statistical analysis of 121 detected miRNAs revealed 42 miRNAs significantly differently expressed between T-cell subsets of eight donors (n = 32 samples, Friedman’s test, P < 0.005, fold difference ≥ 2 in at least one of six comparisons). Top legend (red to blue) depicts range of expression values (log values). Each T-cell subset is characterized by specific miRNA signature. (b) Eight miRNAs, differentially expressed between the four clusters as identified in a, were selected for qRT–PCR validation in a new cohort of donors (n = 14, Table 1, qRT–PCR validation). Relative expression, normalized to the average of RNU44 and RNU48 reference genes is shown. Data are depicted as median values with interquartile range. Statistical analysis: Friedman’s test with Dunn’s multiple comparison post-test. *P < 0.05, **P < 0.01, ***P < 0.001.
extensively in the context of Treg cell function in mice. It was shown that miR-146a positively regulates the suppressive capacity of Tregs by targeting STAT1, a transcription factor involved in the interferon-\(\gamma\) signaling.\(^{23}\) Importantly, no differential expression of miR-146a was noted in our study between patients and controls, or in RA patients between different arms of treatment (MTX and MTX + anti-TNF-\(\alpha\)), suggesting no overt, miR-146a-mediated deregulation of Treg function in RA. In a recent study, Rossi et al.\(^{38}\) described the miRNA signature of 17 defined lymphocyte subsets and focused on naive T-cells. In our analysis, in which we used a slightly different sorting strategy to purify naive CD4\(^+\) T cells, we could confirm the naive Tconv-specific expression of miR-146b-5p and miR-26a. The pattern of miR-125b expression in our data was also consistent with the one described by Rossi et al.\(^{38}\) that is, relatively high levels in naive Tconvs and virtually absent in memory T cells. However, because of the very low absolute expression level, even in the naive Tconvs, miR-125b did not pass the filtering criteria and was not included in our analysis.

Memory Tregs are composed of natural Tregs, which arise in the thymus, and inducible Tregs, which arise in the periphery in response to antigen exposure.\(^{44}\) The recently described possibility to separate natural Tregs and inducible Tregs based on their differential expression of neutropilin-1\(^{45}\) could be used in future studies to determine whether natural Tregs and inducible Tregs share a common miRNA expression signature.

Our profiling did not reveal global RA-specific changes in the miRNA signatures of the four T-cell subsets. However, we found a positive correlation between the expression of miR-451 and DAS28, and more specifically ESR. Furthermore, elevated miR-451 expression correlated with increased serum levels of IL-6 in RA patients with active disease. A negative feedback loop between IL-6 and miR-451 has been described in dendritic cells. IL-6 was shown to induce miR-451, which in turn led to a decreased expression of pro-inflammatory cytokines, such as IL-6, by direct repression of the YWHAZ adapter protein.\(^{32}\) Further studies are warranted to determine whether this proposed relationship between IL-6 and miR-451 exists in T cells.

Our study clearly shows that defined T-cell subsets are characterized by specific miRNA expression signatures. As such, subtle changes in the CD4 + T-cell composition (for example, the ratio of naive to memory T cells) between HC and RA patients may readily influence the outcome of the analysis, especially for miRNAs that show significantly different expression between the naive and memory subsets (for example, miR-21, miR-155 or miR-146a). Recently, Li et al.\(^{14}\) reported increased miR-146a levels in T cells from synovial fluid of RA patients, as well as in T cells treated with TNF-\(\alpha\). In our analysis of naive and memory T cells isolated from peripheral blood, expression of miR-146a did not differ between HC and RA patients. Consistently, we did not detect increased TNF-\(\alpha\) level in the sera of RA patients (data not shown). The synovial fluid T-cell compartment is almost entirely composed of memory T cells\(^{46}\) that are characterized by higher levels of miR-146a than naive T cells (this study and Curtale et al.\(^{43}\)). Moreover, it has been shown that T-cell activation, which takes place in the synovial fluid, significantly induces miR-146a expression.\(^{43}\) Thus, a shift in the composition of synovial fluid T cells together with an ongoing inflammatory state of the joint might be responsible for the relatively high expression of miR-146a observed in synovial fluid T cells. Fulci et al.\(^{47}\) have recently reported increased levels of miR-223 in peripheral blood CD4 + T cells of RA patients. We did not observe such increase in our analysis. This discrepancy could be a result of an interdonor variation.
Overall, our study provides important insight into the expression of specific miRNAs in defined T-cell subsets, especially in naive and memory Tregs. Furthermore, our data underline the necessity to analyze isolated T-cell populations in the search for disease-specific molecular cues such as miRNAs.

**MATERIALS AND METHODS**

Patient’s characteristics

Peripheral blood was obtained from 27 RA patients and 6 HC. All RA patients fulfilled the 1987 ACR criteria for the classification of RA. Twenty-four patients had active disease as defined by the EULAR criteria for active disease (DAS28 score >2.6). For 26 patients, the DAS28 score was calculated at the time of recruitment (for 1 patient, DAS3 score was calculated). IgM rheumatoid factor and anti-cyclic citrullinated peptide antibodies were routinely tested, respectively, by turbidimetrics (Roche, Mannheim, Germany) and fluorescent enzyme immune assay (Phadia, Thermo Fisher Scientific, Uppsala, Sweden). Clinical characteristics of patients, including medication are summarized in Table 1. None of the patients received steroid treatment. The study was approved by the UMC regional institutional medical ethical committee (2009.118) in accordance with the Helsinki declaration of 1964.

Isolation of Treg and Tconv cells

Peripheral blood mononuclear cells from RA patients and HC were isolated by density gradient centrifugation using Lymphoprep (Axis-Shield, Oslo, Norway) immediately after blood withdrawal into heparin-supplemented vacutainer tubes (Becton-Dickinson Biosciences, Franklin Lakes, NJ, USA). CD3 + CD8 – CD45RO – CD25 – and CD3 + CD8 – CD45RO – CD25 + + + T-cells were isolated from peripheral blood mononuclear cells by fluorescence-activated cell sorting (MoFlo, Beckman Coulter, Brea, CA, USA) using anti-human-CD-3 (OKT3, eBioscience, San Diego, CA, USA), anti-human-CD8 (MCD8, IQ Products, Groningen, The Netherlands) anti-human-CD45RO (UCHL1, eBioscience) and anti-human-CD25 (2A3, Becton-Dickinson Biosciences). Cells were immediately lysed with Qiазol reagent (Qiagen, Venlo, The Netherlands).

Intracellular Foxp3 staining

Peripheral blood mononuclear cells were fixed, permeabilized and washed using the Fixation-Permeabilization Buffer Set (eBioscience). Cells were stained with anti-human-CD3 (OKT3, eBioscience), anti-human-CD8 (MCD8, IQ Products) anti-human-CD45RO (UCHL1, eBioscience), anti-human-CD25 (2A3, Becton-Dickinson Biosciences) and anti-human-Foxp3 (clone 206D, BioLegend, San Diego, CA, USA) anti-human-CD8 (MCD8, IQ Products, Groningen, The Netherlands) anti-human-CD45RO (UCHL1, eBioscience). The cell samples were fixed with 4% paraformaldehyde for 10 min and stored at –20 °C. The staining of Foxp3 was performed using anti-human-Foxp3 (clone 206D, BioLegend, San Diego, CA, USA) anti-human-CD8 (MCD8, IQ Products, Groningen, The Netherlands) anti-human-CD45RO (UCHL1, eBioscience) and anti-human-CD25 (2A3, Becton-Dickinson Biosciences). Cells were immediately fixed with 4% paraformaldehyde and permeabilized with 0.1% saponin before it was washed again. Cells were incubated with Foxp3 primary antibody (eBioscience). Cells were then washed with PBS and counterstained with a mixture of 5 μM 4,6-diamidino-2-phenylindole (DAPI; Sigma-Aldrich) and 1 μg/mL propidium iodide (Invitrogen). After washing with PBS, the slides were mounted with ProLong Gold Antifade Reagent with DAPI (Invitrogen) and viewed under a confocal microscope. The data were analyzed using MetaMorph software (Universal Imaging Corporation, West Chester, PA, USA).

RNA isolation

Total cellular RNA was extracted using the mirNeasy Mini Kit (Qiagen), following the manufacturer’s instructions, with an additional chloroform extraction step and a triple washing step. RNA concentrations were quantified using a NanoDrop ND-1000 Spectrophotometer (NanoDrop Technologies, Wilmington, DE, USA). RNA quality was assessed using a NanoDrop ND-1000 Spectrophotometer (NanoDrop Technologies). RNA isolation was performed using the Experion HighSens RNA analysis Kit (Bio-Rad, Hercules, CA, USA). RNA concentrations were quantified using a NanoDrop ND-1000 Spectrophotometer (NanoDrop Technologies). RNA quality was assessed using a NanoDrop ND-1000 Spectrophotometer (NanoDrop Technologies). RNA isolation was performed using the Experion HighSens RNA analysis Kit (Bio-Rad, Hercules, CA, USA). RNA concentrations were quantified using a NanoDrop ND-1000 Spectrophotometer (NanoDrop Technologies). RNA quality was assessed using a NanoDrop ND-1000 Spectrophotometer (NanoDrop Technologies).

Microarray analysis and statistics

Approximately 100 ng of total RNA was dephosphorylated, desalted and labeled with Cy-3 and hybridized to the Agilent Human miRNA Microarray (catalog number G4870A), which contained probes for 1205 human and 144 human viral miRNAs. Arrays were scanned using an Agilent scanner according to the manufacturer’s instructions (Agilent Technologies). Array images were analyzed using Agilent feature extraction software (v10.7.3.1). All further analyses were performed using GeneSpring GX version 12.5 software (Agilent Technologies). TXT files for each array were preprocessed using default settings as follows: threshold raw signals to 1.0, followed by 95 percentile shift normalization. We excluded control probes, miRNAs detected in less than 50% of samples (16 out of 32 samples), and miRNAs with an expression value below –3.5 in more than 25% of samples (8 out of 32 samples), leaving 121 human miRNAs and 4 human viral miRNAs. Hierarchical clustering was performed using Genesis software (Graz University of Technology) and Pearson’s correlation as the distance metric. Differential expression analysis between four treatment groups, irrespective of T-cell subset, was performed using an analysis of variance test with the Benjamini-Hochberg correction for multiple testing. Probes with corrected P-value <0.05 and fold difference ≥2 in at least one of the comparisons between the groups were considered for further analysis. Differential expression analysis across all subjects (n = 8) was performed using a Friedman test between four T-cell subsets, with the Benjamini-Hochberg correction for multiple testing. Probes with corrected P-value <0.005 and a fold difference ≥2 in at least one of the comparisons between the subsets were considered for further analysis. Venn diagrams were constructed using an online tool http://www.bioin-fogp.cnb.cisc.es/tools/venny/.

**Microarray data**

The microarray data have been deposited into Gene Expression Omnibus and are accessible with the following series record number: GSE50646.

**qRT–PCR**

Gene expression levels were analyzed by qRT–PCR. For miRNA-specific complementary DNA synthesis, RNA was reverse transcribed using the TaqMan MicroRNA Reverse Transcription kit in combination with multiplexed reverse transcription primers of TaqMan microRNA Assays (Life Technologies, Carlsbad, CA, USA) for miR-363-3p (ID: 001271), miR-31-5p (ID: 002279), miR-29c-3p (ID: 000587), miR-92a-3p (ID: 000431), miR-320d (ID: 241066_mat), miR-146a-5p (ID: 000468), miR-1246 (ID: 462575_mat), miR-21-5p (ID: 000397), miR-24-3p (ID: 000402), miR-451a (ID: 001141), RNU44 (ID: 001094) and RNU48 (ID: 001060). Complementary DNA synthesis for miRNA was performed using Superscript III RTase (Life Technologies).

The qPCR reaction was performed using qPCR MasterMix Plus (Eurogentec, Liege, Belgium) and Taqman Gene expression assays for miRNAs and for Foxp3 (ID: Hs 01085834_m1) (Life Technologies). Gene-specific primers and probe (Integrated DNA Technologies, Coralville, IA, USA) were used for detection of TATA box binding protein: forward 5′-GCCCGAAAGACCGGATAT-3′, reverse 5′-CGGGTGCTCGCTGCTTCT-3′ and probe 5′-FAM-ATCCCAAGCGGTTGCTGCGG-BHQ-1-3′, and for the detection of RPL1: forward 5′-CTGACGGACACCGACCTAA-3′, reverse 5′-CAAGAGACGCAAGTGGCTGGAAT-3′, and probe 5′-6′-FAM-TACCAGCCTCTTCCTGTGACTC-3′.

All reactions were run in triplicate. Mean cycle threshold (Cv) values for all genes were quantified with the Sequence Detection software (version 2.3, Life Technologies) using AB17900HT thermo cycler (Life Technologies). RNU48 and RNU44 served as endogenous controls for the selected miRNAs, whereas TATA box binding protein and RPL1 served as endogenous controls for Foxp3, resulting in ∆Cv values. Relative expression levels were determined using the 2ΔΔCv formula. For the detection of miR-451 (Figures 3b–e), relative expression levels were calculated with the 2ΔΔCv formula, where RA-29-naive Tconv sample served as a calibrator.

**Quantification of circulating cytokines**

Peripheral blood was collected in anticoagulant-free tubes and incubated to coagulation for 1 h at RT. Serum was collected by centrifugation (1400 g for 10 min) and stored at −80 °C. Sera samples were thawed to quantify levels of cytokines using Human Th1/Th2 Essential 6-plex (Affymetrix, eBioscience) according to the manufacturer’s instruction. Data analyses were performed using StarStation software (Applied Cytometry, Binghamham, UK).

**Statistical analysis**

Statistical analysis of qRT–PCR data was performed with the GraphPad Primer software (San Diego, CA, USA). Comparisons of multiple unpaired samples were performed using the Kruskal–Wallis test with Dunn’s multiple comparison post-test; comparisons of more than two paired samples were performed using the Friedman test with Dunn’s multiple comparison post-test. Comparisons of more than two paired samples with less than six replicates were performed using the repeated measures analysis of variance test with Bonferroni’s multiple comparison post-test.
For correlation comparisons, the Spearman test was used. All statistical analyses were two sided, and the significance level used was \( P < 0.05 \).

**CONFLICT OF INTEREST**

The authors declare no conflict of interest.

**ACKNOWLEDGEMENTS**

We gratefully acknowledge Geert Mesander and Henk Moes for excellent flow cytometrical technical assistance. This study was supported by a grant from the Jan Komelis de Cock Foundation, an Ubbo Emius Fellowship, and an unrestricted research grant from Abbott.
