(Dated: October 20, 2020)

We present exact solutions in Einstein-aether theory in a static spherically symmetric background space with a spacelike aether field, as a difference with the usual selection of timelike aether field. We assume a coupling between the scalar field and the aether field introduced in the aether coefficients. The exact spacetimes describe hairy black hole solutions for which the limits of the Schwarzschild, de-Sitter Schwarzschild and Reissner-Nordström metrics are recovered.

Keywords: Einstein-Aether; Scalar field; Exact solutions; Black holes; Spherically symmetric.

1. INTRODUCTION

Einstein-Aether gravitational theory is a modification of Einstein’s General Relativity where the kinematic quantities of a unitary time-like vector field, known as aether, is introduced in the gravitational Action Integral [1–8]. The introduction of the aether field indicates the selection of a preferred frame which means that there is a violation of the Lorentz symmetry [9]. Specifically, quadratic quantities of the kinematic terms of the aether field are introduced involving no more than two derivatives which lead to a second-order theory as the case of General Relativity. Another important characteristic of the Einstein-Aether theory is that it describes the classical limit of Hořava gravity [10–12]. More precisely, every hypersurface-orthogonal Einstein-Aether solution is a Hořava solution [13]. The equivalence between the Einstein-Aether and Hořava theories is true in terms of exact solution and only. In what regards however other generic results, which follow from the direct form of the field equations, this is not the case [14].

In order to study the effects of Lorentz violation in scalar field theories, it has been proposed the introduction of a scalar field in Einstein-Aether action. The most general gravitational Action Integral with an arbitrary coupling between the inflaton scalar field and the aether field is given in [15]. A specific form of this Action Integral was proposed by Kanno and Soda in [16] where the scalar field is introduced as a quintessence and the couplings of the aether with the gravitational field are functions of the scalar field. This specific model was put forth in order to study the impact of the Lorentz violation on the inflationary scenario. Indeed, it was found that in this model the inflationary stage is divided into two parts; the Lorentz violating stage and the standard slow-roll stage. In the Lorentz violating stage the universe expands as an exact de Sitter spacetime, although the inflaton field is rolling down the potential. Cosmological studies on isotropic and anisotropic spacetimes for the Einstein-Aether theory can be found in [17–28] and references therein.

As far as compact objects are concerned, the dynamics of the field equations for inhomogeneous spherically symmetric models in Einstein-Aether theory are studied in [29] for a non-comoving perfect fluid source. Spherically symmetric spacetimes with a perfect fluid and a scalar field are investigated in [30] and new exact solutions are presented. The integrability of the field equations for static spherical symmetric spacetimes in Einstein-Aether theory with a perfect fluid is investigated in [31] in addition to applying the modified Tolman–Oppenheimer–Volkoff approach.

In the case of vacuum, exact black holes solutions in Einstein-Aether theory are determined in [32], where it is shown that the theory possesses spin-0, spin-1 and spin-2 metric modes whose speeds depend on the four coupling coefficients of the aether field. These solutions have similarities with the Schwarzschild spacetime outside the horizon for a wide range of couplings. Black hole solutions with parameterized post-Newtonian (PPN) parameters identical to those of General Relativity are presented in [33]. In general, Einstein-Aether black holes provide different evolution of gravitational perturbations from that of a Schwarzschild black hole [34]. Charged black hole solutions in an n-dimensional spacetime with or without the cosmological constant term were recently investigated in [35]. The quasi-normal models for Einstein-Aether black hole solutions are studied numerically in [36] and [37], while the matter

accretion in Einstein-Aether black hole solutions is analyzed in [38]. Some rotating spherically symmetric spacetimes in Einstein-Aether theory are given in [39]. For other studies on compact stars in Einstein-Aether gravity we refer the reader to [40–45] and references therein.

In this work we investigate the existence of exact solutions in Einstein-Aether scalar field theory for a static spherically symmetric background space. For the gravitational action we consider the model proposed in [16]. We require the field equations to admit a point-like Lagrangian which indicates that the aether field should be space-like. Models with a space-like aether field have been previously studied in the context of a small violation of the rotation invariance in the early universe [46, 47] or in theories in higher dimensions [48–50]. The gravitational field equations depend on three unknown functions of the scalar field, two are the coupling functions between the aether and the scalar fields, while the third function is the scalar field potential. For certain choices of these functions the system possesses enough integrals of motion for the exact solution to be derived. We show that under specific relations among the constants of integration black hole solutions emerge. What is more, under taking specific limiting values of the parameters, one is led to the known solutions of the Einstein-(Maxwell) equations of General Relativity.

The outline of the paper is as follows: In Section 2 the Action Integral and the general setting of the gravitational theory of our consideration is presented. Section 3 includes the main result of this work; we present the static, spherically symmetric spacetime which consists the general exact solution of the field equations and we give the conditions under which this solution describes black holes of the Einstein-Aether scalar field theory. In Section 4 we prove the existence of circular orbits for massive particles. Finally, in Section 5 we summarize our results and we draw our final conclusions.

2. EINSTEIN-AETHER SCALAR FIELD THEORY

For the gravitational Action Integral we consider the Einstein-Aether scalar field theory

\[ S = \int dx^4 \sqrt{-g} \left( \frac{R}{2} - \frac{1}{2} g^{\mu\nu} \nabla_\mu \phi \nabla_\nu \phi - V(\phi) + \mathcal{L}_{\text{Aether}} \right), \]

where \( R \) is the Ricci scalar, \( g = \text{Det}(g_{\mu\nu}) \) the metric determinant, \( V(\phi) \) the potential of the scalar field and \( \mathcal{L}_{\text{Aether}} \) indicates the Aether field Lagrangian density [16]

\[ \mathcal{L}_{\text{Aether}} = K^{\alpha\beta}_{\mu\nu} \nabla_\alpha u^\mu \nabla_\beta u^\nu + \lambda_0 (u^\mu u_\mu + \varepsilon) \]

where

\[ K^{\alpha\beta}_{\mu\nu} = - (\beta_1(\phi) g^{\alpha\beta} g_{\mu\nu} + \beta_2(\phi) \delta^\alpha_\mu \delta^\beta_\nu + \beta_3(\phi) \delta_\alpha^\mu \delta^\beta_\nu + \beta_4(\phi) u^\mu u^\nu g_{\mu\nu}). \]

The function \( \lambda_0 \) is a Lagrange multiplier and \( \varepsilon = \pm 1 \) the constant which serves to fix the measure of the velocity of the aether field as \( u^\mu u_\mu = -\varepsilon \). On the other hand, the coupling functions \( \beta_1(\phi), \beta_2(\phi), \beta_3(\phi) \) and \( \beta_4(\phi) \) define the coupling between the aether field and the gravitational field. In the typical Einstein-Aether theory the Aether field \( u^\mu \) is assumed to be time-like [2, 3] which means \( \varepsilon = 1 \) in the Lagrangian density (2). However, there exist modifications of the theory where null-like, i.e. \( \varepsilon = 0 \) [51, 52], or space-like \( \varepsilon = -1 \) [48–50] fields are considered. Although various generic models that include space-like vector fields are known to be unstable [53], it is claimed that under certain conditions stable configurations can be constructed [54]. A space-like aether field is what we consider in this work by the means to extract from the action (1) a valid point-like Lagrangian, hence from now on we assume \( \varepsilon = -1 \).

By defining \( J^\mu_\alpha = K^{\nu\rho}_{\alpha\beta} \nabla_\nu u^\beta \) [4], the field equations for the metric can be written as:

\[ R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} = T_{\mu\nu}^{\text{Aether}} + T_{\mu\nu}^{\text{Scalar}} \]

with

\[ T_{\mu\nu}^{\text{Aether}} = 2 \beta_1 (\nabla_\mu u^\alpha \nabla_\nu u_\alpha - \nabla_\alpha u_\mu \nabla_\nu u_\nu) - 2 \left[ \nabla_\alpha \left( u_\mu J^\alpha_\nu \right) + \nabla_\nu \left( u^\alpha J^\nu_\mu \right) - \nabla_\alpha \left( u^\mu J^\nu_\alpha \right) \right] \]

\[ - 2 \beta_4 u^\alpha u^\beta \nabla_\alpha u_\mu \nabla_\beta u_\nu + g_{\mu\nu} \mathcal{L}_{\text{Aether}} + 2 \left[ u^\mu \nabla_\alpha J^\alpha_\nu + \beta_4 u^\nu u^\alpha \nabla_\alpha u_\nu \nabla_\beta u^\beta \right] u_\mu u_\nu \]

and

\[ T_{\mu\nu}^{\text{Scalar}} = \nabla_\mu \phi \nabla_\nu \phi - \frac{1}{2} g_{\mu\nu} \left( \nabla_\alpha \phi \nabla^\alpha \phi + 2 V(\phi) \right) \]
the energy momentum tensors for the aether and scalar fields respectively. Additionally there also exist the equation of motion for the scalar \( \phi \), which is

\[
\nabla_\mu \nabla^\mu \phi - \frac{dV}{d\phi} - \frac{d\beta_1}{d\phi} \nabla^\nu u^\nu \nabla_\mu \phi - \frac{d\beta_2}{d\phi} (\nabla_\mu u^\mu)^2 - \frac{d\beta_3}{d\phi} \nabla^\mu u^\nu \nabla_\nu \phi - \frac{d\beta_4}{d\phi} u^\alpha u^\beta \nabla_\alpha u^\mu \nabla_\mu \phi = 0,
\]

(7)

and for the aether field \( u^\mu \) that leads to

\[
\nabla_\mu F^{\mu\nu} + \beta_4 u^\alpha \nabla_\alpha u^\nu = \lambda_0 u^\nu.
\]

(8)

When the aether field has the additional property \( u^\alpha \nabla_\alpha u^\mu = 0 \), then the fourth function \( \beta_4(\phi) \) becomes irrelevant since all its contributions are trivial. Under this condition it can thus be eliminated from the above equations (see the corresponding relations in [4]).

In cosmological studies the Action Integral (1), has the property that the gravitational field equations admit a point-like Lagrangian. The latter property is extremely useful in the application of well known results and techniques from classical mechanics regarding Noether’s theorem. Solutions of this type regarding a Friedmann–Lemaître–Robertson–Walker and a Bianchi I spacetime are presented in [27, 28].

2.1. Static spherically symmetric spacetime

In this work, for the background space we consider the static, spherically symmetric spacetime with line element

\[
d s^2 = -e^{2(\beta(r)+\lambda(r))} d t^2 + N(r) d r^2 + e^{2\lambda(r)-\beta(r)} \left( d \theta^2 + \sin^2 \theta d \varphi^2 \right)
\]

(9)

and the space-like velocity for the aether

\[
u = (0, N(r), 0, 0),
\]

(10)

for which additionally it holds that \( u^\alpha \nabla_\alpha u^\mu = 0 \). Hence the function \( \beta_4(\phi) \) is excluded from our analysis.

With the above conditions we derive the point-like Lagrangian

\[
L(N, \beta, \beta', \lambda, \lambda') = \frac{e^{3\lambda}}{2N} \left[ -6F(\phi)\lambda'^2 + \frac{3M(\phi)\beta'^2}{4} - \phi'^2 \right] + N \left( e^{\beta + \lambda} - e^{3\lambda}V(\phi) \right),
\]

(11)

where the prime denotes total derivative with respect to the variable \( r \). The functions \( F(\phi), M(\phi) \) are defined as

\[
F(\phi) = \beta_1(\phi) + 3\beta_2(\phi) + \beta_3(\phi) - 1,
\]

(12)

\[
M(\phi) = -2\left[ 1 + 2(\beta_1(\phi) + \beta_3(\phi)) \right].
\]

(13)

The gravitational field equations (4) are equivalent to the Euler-Lagrange equations \( \frac{d}{d\varphi} \left( \frac{\partial L}{\partial \phi'} \right) - \frac{\partial L}{\partial \phi} = 0, \frac{d}{d\varphi} \left( \frac{\partial L}{\partial \phi'} \right) - \frac{\partial L}{\partial \phi} = 0 \), with constraint equation \( \frac{d}{d\varphi} \frac{\partial L}{\partial \phi' \phi'} = 0 \). For the scalar field \( \phi \) we assume that it inherits the Killing symmetries of the background space, which means that the equation of motion (7) is given by the Euler-Lagrange equation \( \frac{d}{d\varphi} \left( \frac{\partial L}{\partial \phi' \phi'} \right) - \frac{\partial L}{\partial \phi} = 0 \). Last but not least, the field equation (8) just serves to define the multiplier \( \lambda_0 \). Having performed this consistency check we can concentrate our analysis on the reduced system described by (11).

3. BLACK HOLE SOLUTIONS

The nonlinear gravitational field equations depend on three unknown functions, namely the coupling functions \( F(\phi), M(\phi) \) and the scalar field potential \( V(\phi) \). In the following we consider specific functional forms of these unknown functions so as to extract closed-form solutions for the field equations.
3.1. The generic $F(\phi) = \mu \phi^2$, $M(\phi) = \nu \phi^2$, $V(\phi) = 0$ case

In the particular case where $F(\phi) = \mu \phi^2$, $M(\phi) = \nu \phi^2$ and $V(\phi) = 0$, with $\mu, \nu$ constants, the system admits three linear in the velocities integrals of motion:

$$I_1 = \frac{e^{3\lambda} \phi^2}{N} (2\mu \lambda' + \nu \beta'),$$

$$I_2 = \frac{e^{3\lambda} \phi}{N} (3\mu \lambda' - \phi'),$$

$$I_3 = \frac{e^{3\lambda} \phi}{N} \left[ \phi ((3\mu \nu \lambda - \nu \ln \phi) \beta' - (3\mu \nu \beta + 2\mu \ln \phi) \lambda') + (\nu \beta + 2\mu \lambda) \phi' \right].$$

The fact that a quadratic dependence of $F$ and $M$ in $\phi$ gives rise to this type of conservation laws is also known from the cosmological case, see the recent [55].

The above conservation laws can be used in conjunction to the field equations in order to derive the general solution of the system. We avoid the presentation of the cumbersome but straightforward procedure and we focus in the end result which leads to the line element:

$$ds^2 = -\frac{e^{4A_1r}}{\left[ \cosh \left( \sqrt{\kappa_1}r \right) \right]^{\frac{2(\mu - \mu_1)}{\mu(\mu - \nu - 1) + 2\nu}}} dt^2 + \frac{\nu^2 e^{2A_1r}}{\left[ \cosh \left( \sqrt{\kappa_1}r \right) \right]^{\frac{6\nu/2(\nu - 1) + 2\nu}{\mu(\mu - \nu - 1) + 2\nu}}} dr^2$$

$$+ \frac{k_4 e^{A_2r}}{\left[ \cosh \left( \sqrt{\kappa_1}r \right) \right]^{\frac{2(\nu - 1)}{\mu(\mu - \nu - 1) + 2\nu}}} (d\theta^2 + \sin^2 \theta d\varphi^2)$$

and the scalar field

$$\phi(r) = \frac{e^{A_3r + \frac{A_4r}{\kappa_1}}} {\sqrt{3\kappa_1 \kappa_4 \mu}} \left[ \cosh \left( \sqrt{\kappa_1}r \right) \right]^{\frac{3}{\mu(\mu - \nu - 1) + 2\nu}},$$

where $k_4, \kappa_i, A_i$, $i = 1, 2, 3$ are all constants. The latter three constants, $A_1, A_2, A_3$, are not independent, but are the combinations:

$$A_1 = \frac{2\kappa_2 \nu}{3\mu + 2} + \frac{2\sqrt{3\nu} (2\mu + 1) \sqrt{2\kappa_2 \nu (3\mu \nu - \mu + 2\nu) + 3\kappa_1 \mu (3\mu + 2)}}{(3\mu + 2) (3\mu \nu - 1) + 2\nu),}$$

$$A_2 = \frac{2\kappa_2 \nu}{3\mu + 2} - \frac{2\sqrt{3\nu} (\mu + 1) \sqrt{2\kappa_2 \nu (3\mu \nu - 1) + 2\nu) + 3\kappa_1 \mu (3\mu + 2)}}{(3\mu + 2) (3\mu \nu - 1) + 2\nu),}$$

$$A_3 = -\frac{2\kappa_2 \nu}{3\mu + 2} - \frac{\sqrt{3\nu} \sqrt{2\kappa_2 \nu (3\mu \nu - \mu + 2\nu) + 3\kappa_1 \mu (3\mu + 2)}}{(3\mu + 2) (3\mu \nu - 1) + 2\nu).}$$

In order to judge if we have a black hole solution we first need to make a transformation of the form

$$\frac{k_4 e^{A_2 r}}{\left[ \cosh \left( \sqrt{\kappa_1}r \right) \right]^{\frac{2(\nu - 1)}{\mu(\mu - \nu - 1) + 2\nu}}} \mapsto r^2$$

(20)

to associate the function multiplying the unit sphere part of the metric, $d\Omega^2 = d\theta^2 + \sin^2 \theta d\varphi^2$, with some radial distance. The mapping (20) forms an algebraic equation which cannot be solved for all the values of the constants as $r = r(\tilde{r})$. However, if we enforce the restriction

$$A_2 = -\frac{2(\mu + \nu)}{\mu(3\nu - 1) + 2\nu} \sqrt{\kappa_1},$$

(21)

then the transformation

$$r(\tilde{r}) = \frac{1}{2\sqrt{\kappa_1}} \ln \left( \frac{2\kappa_4 \sqrt{\frac{3\nu - 1 + 2\nu}{\mu(\mu - \nu - 1)}} \sqrt{k_4 - \frac{2(\mu + \nu)}{\mu(\mu - \nu - 1)}} - 1} \right)$$

(22)
realizes the mapping (20) and the resulting line element reads

\[
\begin{align*}
    ds^2 &= -r^2 \frac{6\mu}{\kappa_4} \left( 1 - 2\kappa_4 \frac{\mu(3\nu-1)+2\nu}{2(\mu+\nu)} r^{-3\mu+\mu-2\nu} \right) \frac{A_1}{\kappa_4} + \frac{A_1}{\kappa_4} \left( \frac{3\mu+\nu}{\mu(3\nu-1)+2\nu} \right) dt^2 \\
    &\quad + \frac{e^C r^{4\mu}}{(1 - 2\kappa_4 \frac{\mu(3\nu-1)+2\nu}{2(\mu+\nu)} r^{-3\mu+\mu-2\nu})} \left( \frac{A_1}{\kappa_4} + \frac{\nu-2\mu}{\mu(3\nu-1)+2\nu} \right) d\theta^2 + r^2 (d\theta^2 + \sin^2 \theta d\varphi^2)
\end{align*}
\]  

(23)

For simplicity we drop the tilde over \( r \), but it is to be understood that from now on the \( r \) appearing is different than the one we had in (17). In addition, some constant scalings in the \( t \) variable have been made in order to simplify the line element. The constant \( C \) is a reparametrization of the constant \( \kappa_3 \) given by

\[
\kappa_3 = \ln \left( \frac{A_1 \mu(3\nu-1)+2A_1 \nu-6, \kappa_3 \mu(3\nu-1)+2\nu}{\kappa_4} \mu(3\nu-1)+2\nu \right) + C.
\]  

(24)

Finally, the corresponding scalar field is

\[
\phi(r) = (-1)^{A_1 \mu(3\nu-1)+2A_1 \nu-6, \kappa_3 \mu(3\nu-1)+2\nu} \sqrt{\frac{2}{3}(\mu + \nu)} \sqrt{3\mu - 2\nu} \left( \frac{A_1}{\sqrt{1} \mu(3\nu-1)+2\nu} \right) \left( \frac{3\mu+\nu}{\mu(3\nu-1)+2\nu} \right) \]  

(25)

\[\times r^{2\mu} \left( 1 - 2\kappa_4 \frac{\mu(3\nu-1)+2\nu}{2(\mu+\nu)} r^{-3\mu+\mu-2\nu} \right) \frac{1}{2} \left( \frac{A_1}{\sqrt{1} \mu(3\nu-1)+2\nu} + \frac{3\mu+\nu}{\mu(3\nu-1)+2\nu} \right).\]

3.2. Distinguishing black hole solutions

In order for the line element (23) to be able to describe a black hole space-time we need at least to enforce two further conditions: (i) demand the power of \( r \) in the parenthesis to be negative, i.e.

\[
-3\mu\nu + \mu - 2\nu < 0
\]  

(26)

and (ii) at the same time the power of the first parenthesis to assume the value of an odd positive number

\[
\frac{A_1}{\sqrt{1}} + \frac{\nu-2\mu}{\mu(3\nu-1)+2\nu} = 2k + 1, \quad k \in \mathbb{N}.
\]  

(27)

so that the \( g_{tt} \) and \( g_{rr} \) components of the metric can interchange signs when crossing the horizon. Of course we also need to impose \( \kappa_4 > 0 \), so that an horizon exists at a real distance \( r = r_h = 2\mu(\mu+\nu) \sqrt{\kappa_4} (2\kappa_4)^{-\mu(3\nu-1)+2\nu} \), where from now on for the simplicity of the line element we define \( \kappa = \kappa_4 \mu(3\nu-1)+2\nu \).

The above two conditions can be satisfied for an infinite combination of \( \mu \) and \( \nu \) values. To demonstrate this, let us take the case \( k = 0 \) in (27), so that

\[
\frac{A_1}{\sqrt{1}} + \frac{\nu-2\mu}{\mu(3\nu-1)+2\nu} = 1.
\]  

(28)

By using the above relation together with (19) and the necessary condition (21), which is needed for the special solution (23) to exist, we see that they are all compatible for every nonzero value of \( \mu > -1 \) and \( \kappa_4 > 0 \) if \( \nu = 2\mu \). If we insert the latter however in (26) we see that we obtain the additional restriction \( \mu > -\frac{1}{2} \).

As a result we have a black hole of the form

\[
\begin{align*}
    ds^2 &= - \left( 1 - 2\kappa \frac{r}{\mu+1} \right) dt^2 + \frac{e^C r^{4\mu}}{1 - \frac{2\mu}{r^{2\mu+1}}} dr^2 + r^2 (d\theta^2 + \sin^2 \theta d\varphi^2)
\end{align*}
\]  

(29)

corresponding to the scalar field

\[
\phi(r) = \pm \frac{e^C r^{2\mu}}{\sqrt{\mu(2\mu+1)}}
\]  

(30)
with the restriction $\mu > -\frac{1}{2}$ (and of course $\mu \neq 0$). Notice that if $\mu > 0$ the scalar field $\phi$ is imaginary, which makes its contribution in the action to be that of a phantom field. On the contrary, when $-\frac{1}{2} < \mu < 0$ we have a solution with a canonical scalar field.

In addition, we observe that apart from the constant $\kappa$, which can be associated with the mass of the black hole, the line element (29) carries a dependence on the constant $C$ that emerges from the matter content, i.e. the scalar field. We thus deduce that this is a hairy black hole since another constant appears in addition to the mass (in this particular case we have not considered an electromagnetic field or a rotating solution for an additional charge or an angular momentum respectively). Through the use of curvature scalars it is a simple task to indeed verify that both $\kappa$ and $C$ are essential for the geometry, i.e. they can not be absorbed with a diffeomorphism [56]. Take for example the triplet $q = (q_1, q_2, q_3)$ with $q_1 = R$, $q_2 = \nabla_{\alpha} R \nabla^\alpha R$ and the Kretschmann scalar $q_3 = R_{\alpha\beta\gamma\delta} R^{\alpha\beta\gamma\delta}$; then the matrix $J_{ij} = \frac{2q_i}{\mu + 1}$ with $v = (r, \kappa, C)$, $i, j = 1, 2, 3$, is invertible. As a result, you can in principle use one of the equations defined by the $q_i$ to solve with respect to $r$ and substitute in the remaining couple, then two algebraically independent relations of the form $f_1(q_1, q_2, q_3, \kappa, C) = 0$, $f_2(q_1, q_2, q_3, \kappa, C) = 0$ will be formed, involving both $\kappa$ and $C$, and with the property of being invariant under local coordinate transformations. Hence, neither $\kappa$ nor $C$ can be eliminated through such a mapping.

We observe that for $\mu \rightarrow 0$ and by assuming $e^C \rightarrow 1$, the spacetime (29) takes the form of the Schwarzschild black hole, thus for small values of $\mu$ and $C = 0$ the line element (29) becomes

$$ds^2 = ds^2_{\text{Schwarzschild}} + \mu \left[ -4\kappa \ln \frac{r}{r - 3\kappa} \frac{dt^2}{dr} + \frac{4r(r - 3\kappa) \ln r}{(r - 2\kappa)^2} dr^2 + \mathcal{O}(\mu^2) \right]$$

(31)

Alternatively, we may introduce the transformation $r = (2\mu + 1) \frac{1}{\kappa + \frac{1}{2}} R$ to write the line element (29) as

$$ds^2 = - \left(1 - \frac{2\kappa}{(1 + 2\mu) R} \right) dt^2 + e^C \left( 1 - \frac{2\kappa}{(1 + 2\mu) R} \right)^{-1} dR^2 + (1 + 2\mu) \frac{1}{\kappa + \frac{1}{2}} R \left( d\theta^2 + \sin^2 \theta d\varphi^2 \right).$$

(32)

The above metric, although it is distinct, it resembles in some parts solutions expressing non-asymptotically flat black holes in the context of Einstein-Maxwell-dilaton gravity presented in [57].

### 3.3. The case of cosmological constant

It is easy to add a cosmological constant $\Lambda$ to the previous solution (29). In particular, we observe that the line element

$$ds^2 = - \left(1 - \frac{2\kappa}{r^{2\mu + 1} + lr^2} \right) dt^2 + \frac{e^C r^{4\mu}}{1 - \frac{2\kappa}{r^{2\mu + 1} + lr^2} + lr^2} dr^2 + r^2 \left( d\theta^2 + \sin^2 \theta d\varphi^2 \right),$$

(33)

where $l$ is a constant, together with the same expression for the scalar field given by (30), satisfy the field equations with $F(\phi) = \mu \phi^2$, $M(\phi) = \nu \phi^2$, $V(\phi) = \Lambda$, with $l = -\frac{2\mu + 1}{2\mu + 3} \Lambda$. That is it forms the solution when a cosmological constant $\Lambda$ is also considered.

However we must note that another singularity is added in this case when $r \rightarrow +\infty$ for $-\frac{1}{2} < \mu < 0$ since the scalar curvature is now

$$\mathcal{R} = \frac{2}{r^2} + 2e^{-C} \left( \frac{8(\mu - 1) \mu \kappa}{r^{3(2\mu + 1)}} + \frac{(4\mu - 1) \mu \kappa}{r^{2(2\mu + 1)}} + \frac{6l(\mu - 1)}{r^{4\mu}} \right).$$

(34)

This means that in the presence of a cosmological constant we have to further restrict $\mu$ to be positive so that the second singularity at infinity is avoided. Again, we notice that at the limit $\mu \rightarrow 0$, $C = 0$, the known from General Relativity solution with a cosmological constant is obtained with $\mathcal{R} = -12l$.

### 3.4. The case of electrostatic field

Alternatively (or in addition to the above) one may consider an appropriate electrostatic field. In this case we obtain

$$ds^2 = - \left(1 - \frac{2\kappa}{r^{2\mu + 1} + (1 - 4\mu^2) \frac{e^{-C} Q^2}{r^2}} \right) dt^2$$

$$+ \frac{e^{C} r^{4\mu}}{1 - \frac{2\kappa}{r^{2\mu + 1} + (1 - 4\mu^2) \frac{e^{-C} Q^2}{r^2}}} dr^2 + r^2 \left( d\theta^2 + \sin^2 \theta d\varphi^2 \right)$$

(35)
which corresponds to a solution in the presence of an electric field with potential \( U(r) = \frac{Q}{r^{2+\mu}} \), if we include in the right hand side of (4) the energy momentum tensor

\[
T_{\mu\nu}^{EM} = 2F_{\mu\nu}F_{\nu\rho}^{\rho} - \frac{1}{2}g_{\mu\nu}F_{\kappa\lambda}F^{\kappa\lambda},
\]

where \( F_{\mu\nu} = \nabla_\mu A_\nu - \nabla_\nu A_\mu \) and \( A = U(r)dt \). Once more the solution is compatible with the expression (30) for the scalar field.

4. **EXISTENCE OF CIRCULAR ORBITS**

In this section we investigate whether the new black hole solution (29) supports stable trajectories of massive particles.

Let’s assume the affinely parametrized geodesic equations for a time-like particle in a space-time whose line element is (29). The system is described by the Lagrangian

\[
L_{\text{Geodesic}} = -\frac{1}{2} \zeta (r) \left( \frac{dt}{ds} \right)^2 + \frac{1}{2} e^{C(r)\mu} \left( \frac{dr}{ds} \right)^2 + \frac{1}{2} r^2 \left( \frac{d\Omega}{ds} \right)^2,
\]

where \( d\Omega^2 = d\theta^2 + \sin^2 \theta d\varphi^2 \) and \( \zeta (r) = 1 - \frac{2\mu}{r^{2+\mu}} \). The geodesic equations admit the conservation laws

\[
\zeta (r) \frac{dt}{ds} = E, \quad r^2 \sin^2 \theta \frac{d\varphi}{ds} = L_0
\]

while the Hamiltonian of (37) in the equatorial plane \( \theta = \frac{\pi}{2} \) and for the case of a timelike particle yields

\[
e^{C} e^{4\mu} \left( \frac{dr}{ds} \right)^2 = \mathcal{E}^2 - \left( 2 + \frac{L_0^2}{r^2} \right) \zeta (r)
\]

As previously, we define the new variable \( dR = r^{2\mu} \) which gives \( R = \frac{1}{2\mu+1} r^{2\mu+1} \), hence the latter equation becomes

\[
e^{C} \left( \frac{dR}{ds} \right)^2 = \mathcal{E}^2 - V_g (R)
\]

where now

\[
V_g (R) = 2 \left( 1 - \frac{\mu}{R} \right) + \frac{\bar{L}^2}{R^{2\mu}} - \frac{\tilde{K}}{R^{1+\mu}}
\]

and \( \bar{L}^2 = \left( \frac{\mu}{2} \right)^2 L_0^2 \), \( \bar{K} = \tilde{\mu} \kappa \) and \( \tilde{\mu} = \frac{2}{1+2\kappa} \). For real valued scalar field, that is, for \( -\frac{1}{2} < \mu < 0 \), i.e. \( \tilde{\mu} > 0 \) and for large values of \( R \), which also means large values of \( r \), the dominant terms are those of the Newtonian potential, that is \( V_g (R) \approx 2 \left( 1 - \frac{\kappa}{R} \right) \).

We consider the special case where \( \bar{K} = 1 \), \( \bar{L}^2 = 10 \) and \( \tilde{\mu} = 3 \), then \( V_g (R) = 2 \left( 1 - \frac{\kappa}{R} \right) + \frac{10}{R^2} - \frac{10}{R^3} \) and \( \frac{d^2V_g (R)}{dR^2} = \frac{10}{R^3} (20 - 15R + R^2) \), thus the stationary point \( \frac{dV_g (R)}{dR} = 0 \) is found on the positions \( R_1 \approx 1.61 \) and \( R_2 \approx 2.81 \). For this set of values the horizon is located on \( R = 1 \), thus both stationary points are outside the horizon. Point \( R_1 \) is unstable, that is \( \frac{d^2V_g (R)}{dR^2} \big|_{R=R_1} < 0 \) while point \( R_2 \) is an attractor, since \( \frac{d^2V_g (R)}{dR^2} \big|_{R=R_2} > 0 \). In Fig. 1 we present potential \( V_g (R) \) for \( \bar{K} = 1 \), \( \bar{L}^2 = 10 \) from which it is clear that there are periodic solutions around the stationary point \( R_2 \).

In order to understand the deviation from the Schwarzschild solution we consider \( \bar{K} = 1 \), \( \bar{L}^2 = 3 \) and in Fig. 2 we present the qualitative evolution of \( R(s) \) for various values of \( \tilde{\mu} \). We observe that there is a deviation from the Schwarzschild solution in the period of the oscillation. The trajectories presented in Fig. 2 are for the same initial conditions.

5. **CONCLUSIONS**

In this work we studied the existence of exact static spherically symmetric solutions in Einstein-Aether scalar field gravity with an interaction between the scalar field and the Aether. For the gravitational theory proposed by Kanno
and Soda [16] and for the requirement the field equations to admit a point-like Lagrangian we were able to find analytic and exact solutions for specific functional forms of the unknown functions. We distinguished conditions that are necessary for certain black hole space-times to emerge. The solutions correspond to a massless scalar field and can be modified appropriately to introduce a cosmological constant and/or an electrostatic field to contribute in the effective fluid.

The black hole solutions that we presented admit an additional (apart from the mass) constant of integration $C$ in the metric. The latter emanates from the scalar content of the theory and allows as to characterize these solutions as hairy black holes. Surprisingly enough, a limit exists that connects the resulting space-time to the known static black hole solutions of General Relativity. When we have $\mu \to 0$, $C \to 0$, the solutions that we found tend to the Schwarzschild, the de-Sitter Schwarzschild and Reissner-Nordström metrics. Hence, we can say that $\mu$ in these cases appears as a measure of the radial modification produced due to the aether having a velocity in the $r$ direction, that is, due to the Lorentz violation.

We need to mention that the solutions we derived so far correspond to specific combinations of the free parameters $\mu$ and $\nu$. However, these combinations are not unique in giving black hole space-times. For instance, if we take $\mu = -\frac{1}{6}$, $\nu = 1$ we get the exact solution

$$ds^2 = -r^{\frac{16}{9}} \left(1 - \frac{2\kappa}{r^2}\right)^3 dt^2 + \frac{e^{Ct^{-\frac{4}{3}}}r^{-\frac{2}{3}}}{(1 - \frac{2\kappa}{r^2})^3} dr^2 + r^2 \left(d\theta^2 + \sin^2 \theta d\phi^2\right)$$

(42)

with scalar field

$$\phi(r) = \pm \sqrt{\frac{3}{5}} \frac{e^{\frac{4C}{3}}}{r^{\frac{2}{3}}(1 - \frac{2\kappa}{r^2})},$$

(43)

which is distinct from what we had previously. The resulting space-time admits a curvature singularity at the origin $r = 0$, while $r = \sqrt{2\kappa}$ is a coordinate singularity. This indicates that there is a rich structure in the theory which leads to various black hole solutions.

Finally, it is straightforward to see that the above results have their cosmological counterparts which are obtained through the transformations: $t \leftrightarrow r$, $\phi \leftrightarrow i\phi$. That is, we need only interchange $t$ with $r$ in the above line elements and wherever we have $\phi$, put in its place $i\phi$. For example if we take (29) and (30) the cosmological dual solution is

$$ds^2 = -\frac{e^{Ct^{4\mu}}}{1 - \frac{2\kappa}{2\mu+1}} dt^2 + \left(1 - \frac{2\kappa}{t^{2\mu+1}}\right) dr^2 + r^2 \left(d\theta^2 + \sin^2 \theta d\phi^2\right)$$

(44)
FIG. 2: Qualitative evolution of $R(s)$ around the periodic solution for various values of $\bar{\mu}$. Solid line is for $\bar{\mu} = 2$, which correspond to the Schwarzschild solution ($\mu = 0$), dashed line is for $\bar{\mu} = 2.01$, dotted line is for $\bar{\mu} = 2.1$ and dashed-dotted line is for $\bar{\mu} = 3$. The evolution is for $\bar{K} = 1, \bar{L}^2 = 3$ and $C = 0$.

with

$$\phi(t) = \pm \frac{e^\frac{C}{t} t^{2\mu}}{\sqrt{\mu(2\mu + 1)}} \tag{45}$$

and it corresponds to a theory with $F = -\mu\phi^2$ and $M = -\nu\phi^2$. Since there is no obligation for having an horizon here, $\kappa$ can be taken negative. We remark that in the case of cosmological solutions the aether field is timelike.

In a future work we plan to extend our study on the thermodynamics properties of these new black hole solutions.
