CONTRIBUTORS
E.P.F.C., J.S.H, J.J.O and C.K.F. contributed to the concept and design of the study. E.P.F.C., J.S.H, J.J.O, T.S., A.B., P.P., and C.K.F. designed the survey questions. E.P.F.C., E.R. and K.M. were involved in study recruitment by sending SMS invitations to potential participants. E.P.F.C. oversaw the study, performed data analysis and wrote the first draft of the manuscript. All authors involved in data interpretation revised the manuscript critically for important intellectual content and approved the final version of the manuscript.

ACKNOWLEDGEMENTS
We would like to thank Afrizal Afrizal for his assistance with data extraction identifying the PrEP clients at the Melbourne Sexual Health Centre.

FUNDING
E.P.F.C and C.K.F are supported by an Australian National Health and Medical Research Council (NHMRC) Investigator Grant (GNT1172873 and GNT1172900, respectively. J.S.H is supported by a NHMRC Senior Research Fellowship (GNT1136117). J.J.O. is supported by an Australian NHMRC Early Career Fellowship (APP1104781).

CONFLICT OF INTERESTS
E.P.F.C. has received a research grant and honoraria from Gilead Pharmaceuticals on HIV and PrEP research outside the submitted work. All other authors have no conflicts of interest to declare.
ABSTRACT
We surveyed 204 MSM who were PrEP users. One in four daily PrEP users stopped taking PrEP during the COVID-19 pandemic and 5% switched to on-demand PrEP. Most men reduced PrEP use because they stopped having casual sex and reduced the number of casual partners during the COVID-19 pandemic.

INTRODUCTION
The first case of coronavirus disease (COVID-19) was reported in China in December 2019 and it became a global pandemic on March 11, 2020. The first COVID-19 case in Australia was identified on January 25, 2020, and after an initial rapid rise mid-March, the number of cases fell to low levels by late-April where they have remained.[1] This fall followed the implementation of several major public health responses in March and April 2020, including the closure of Australia’s border to all visitors, enforced quarantine for 14 days after international travel, social distancing rules, staying home restriction and banning all non-essential services (hereafter referred to as ‘lockdown’).[1] We hypothesised that lockdown had an impact on sexual practices thereby reducing HIV risk.[2, 3] We also hypothesised that men who have sex with men (MSM) who take pre-exposure prophylaxis (PrEP) to reduce their risk of HIV acquisition, may also change the way they use PrEP as a result of lockdown. This study aimed to examine the proportion of MSM who have changed their PrEP use during the lockdown in response to the COVID-19 pandemic and their reasons.

METHOD
We identified a list of clients who (1) were aged ≥18 years; (2) were men who have sex with men; (3) had their PrEP care and management at the Melbourne Sexual Health Centre (MSHC) in Australia between January and April 2020 (including those who had appointments booked but cancelled their PrEP appointments during the period). All clients attending MSHC are asked to indicate whether they wish to provide consent to receive a short message service (SMS) from MSHC. We conducted a cross-sectional online survey between May 1 and May 10, 2020, by sending an SMS invitation to the clients who fulfilled the above-mentioned eligibility criteria and had consented to receive an SMS from MSHC. The SMS included a unique link to an online short survey. A description of the study and the participant information sheet were provided on the first page of the survey. Participants were required to provide consent to participate in the survey by selecting the ‘Agree’ button before commencing the survey. The survey investigated how they used PrEP during two-time intervals: (i) between January and February (before lockdown); and (ii) the time they completed the survey in early May (during lockdown). Our survey captured whether they used PrEP daily, on-demand (or event-driven) or not at all. For those who indicated they had changed the way they used PrEP, an extra question was asked about the reasons for changing. Participants could provide multiple reasons why they changed their PrEP use during lockdown. No other personally identifiable information was
collected in the survey. Ethics approval was obtained from the Alfred Hospital Ethics Committee(#249/20).

Descriptive statistics were used to determine the frequency and proportion of PrEP use among MSM before and during lockdown. The 95% confidence intervals (CI) of the proportion was calculated using binomial exact methods. All statistical analyses were performed using STATA (version 14; College Station, TX, USA).

RESULTS
A total of 450 individual MSM had made an appointment (including those who had cancelled) at the PrEP clinic at MSHC between January and April 2020 and 437 (97.1%) men provided consent to receive an SMS from the clinic. An SMS with a unique link to the survey was sent to all 437 men and 205 men (46.9%) provided consent to participate in the survey. One man provided consent to participate but did not complete the survey and was excluded from the analysis. Of the remaining 204 men, age ranged from 21 to 73 years (median 36; IQR 31-48) and more than half were born in Australia (62.3%;n=127). The median time men reported being on PrEP was 2.7 (IQR 1.2-3.7) years.

Between January and February 2020 (before lockdown), 178 men (87.3%) used daily PrEP, 11 (5.4%) used on-demand PrEP, and 15 (7.4%) did not take PrEP. Overall, 57 men (27.9%;95%CI:21.9%-34.6%) changed the way they used PrEP in May (during lockdown). There were no differences in age between those who did or did not change PrEP use (median age=36 years versus 36 years respectively;p=0.364) nor by the time they had been taking PrEP (median time=2.7 years versus 2.6 years respectively;p=0.686).

Of the 178 men who used daily PrEP before lockdown, 130 (73.0%;95%CI:65.9-79.4%) continued to use daily PrEP but eight (4.5%;95%CI:2.0-8.7%) changed to on-demand PrEP and 40 (22.5%;95%CI:16.6-29.3%) stopped using PrEP during lockdown (Figure 1a). Furthermore, of the 11 men who used on-demand PrEP before lockdown, five (45.5%;95%CI:16.7-76.6%) continued but six (54.5%;95%CI:23.4-83.3%) stopped using PrEP during lockdown.

Of the 54 men who reduced the use of PrEP during lockdown (i.e. changed from daily PrEP to on-demand or stop taking PrEP; or changed from on-demand PrEP to stop taking PrEP), the most frequent reason reported was not engaging in casual sex during lockdown (n=47;87.0% [95%CI:75.1-94.6%])(Figure 1b). Some men also reported they reduced the number of casual partners (n=19;35.2% [95%CI:22.7-49.4%]) and group sex (n=9;16.7% [95%CI:7.9-29.3%]). A small proportion of men were concerned about catching SARS-CoV-2 while visiting the clinic during lockdown (n=8;14.8%
and very few clients reported difficulties in making a PrEP appointment (n=4; 7.4% [95%CI: 2.1-17.9%]).

Of the 15 who did not use PrEP before lockdown, 12 (80.0%) continued not using PrEP but three (20.0%) switched to daily PrEP during lockdown. Of the three men who changed to daily PrEP, one man reported decreased condom use, another man commented decreased anxieties and one man did not provide a specific reason.

DISCUSSION
This cross-sectional survey showed that one in four MSM daily PrEP users stopped using PrEP during lockdown and about 5% of MSM had switched from daily PrEP to on-demand PrEP; however, the majority of MSM daily PrEP users kept taking daily PrEP during lockdown in the COVID-19 pandemic.

On-demand PrEP is highly effective in preventing HIV as shown in a clinical study.[4] On-demand PrEP is recommended as an alternative option of PrEP dosing in Australian guidelines:[5] however, we found that only a very small proportion of MSM were taking on-demand PrEP (5.4%) before the COVID-19 lockdown, which is consistent with the estimate from a community-based survey in Melbourne (4.0%) in 2019.[6] Compared with international studies, the proportion of MSM who used on-demand PrEP in Melbourne is lower than other settings such as London (16%)[7] and Amsterdam (27%).[8] We found that one in four MSM reduced PrEP dosing during lockdown and the most frequent reason for reducing or ceasing PrEP was not having casual sex during lockdown and a reduced number of casual partners, and no men reported having increased number of casual partners and condomless sex, suggesting that they were unlikely to have an increased risk of acquiring HIV. This is also consistent with past studies showing on-demand PrEP users tend to have a lower number of casual sex partners compared to daily PrEP users.[9] Although the participants in this study are regular PrEP patients at our clinic, it is unclear whether they have consulted with their doctors about reducing PrEP use to on-demand PrEP or ceasing PrEP all together. A previous Australian study has shown that only 37% of PrEP users had prior knowledge about on-demand PrEP and more importantly, most of them received this knowledge from social media and the internet.[10] It is important to ensure MSM receive the correct information and knowledge and use on-demand PrEP correctly and safely if they switch from daily to on-demand PrEP.

Adequate HIV prevention access is also important during this lockdown period. Similar to other settings,[11] our clinic was open during the lockdown period to provide HIV testing and post-exposure prophylaxis (PEP). The unique of this lockdown may provide opportunities in eliminating HIV.
This study has several limitations. First, this study was conducted among PrEP users who had their PrEP care and management at a large metropolitan sexual health clinic. In Australia, individuals can also access PrEP from private GPs and through personal importation; these men may use PrEP differently. Hence, our findings may not be generalisable to all MSM. Second, we only asked men why they changed their PrEP use during lockdown. For men who continued using PrEP daily, we did not ask whether they had changed their sexual practices during the lockdown period. Thirdly, the use of post-exposure prophylaxis (PEP) was not asked during the lockdown period. However, data from a sexual health clinic in London has shown that there was an 80% reduction on PEP within four weeks of the lockdown in the UK. [11]

In conclusion, we found that a quarter of daily PrEP users stopped taking PrEP primarily due to stopping casual sex during lockdown in the COVID-19 pandemic, while a small proportion of MSM switched from daily to on-demand PrEP. Future studies will be required to understand the level of knowledge and understanding of on-demand PrEP among those who switched their PrEP dosing. A follow-up study among those who switched their PrEP dosing would be useful to determine whether they would change back to daily PrEP once they resume their sexual activities after the lockdown or easing of restrictions.

(A)

(B)

Stopped having casual sex during COVID-19: 87.0%
Decreased number of casual partners: 35.2%
I think my risk of getting HIV is low: 24.1%
Decreased group sex: 16.7%
Concerned about catching COVID-19 when visiting clinics: 14.8%
Having difficulties in making a PrEP appointment: 7.4%
Having a regular/long term partner*: 5.6%
Unable to afford the cost of medication and/or consultation fee: 5.6%
Increased condom use: 3.7%
Concerned about difficulties in accessing PrEP in the post COVID-19 period*: 1.9%
Decline in renal function*: 1.9%
Having difficulties in accessing PrEP: 1.9%
Increased number of casual partners: 1.9%
