Summary
What is already known on this topic?
Streptococcus suis (S. suis) is a zoonotic pathogen causing disease in humans and animals, and the emergence of its increased resistance to antimicrobial agents has become a significant challenge in many countries.

What is added by this report?
Using whole genome sequencing data to accurately predict antimicrobial resistance determinants, it was found that the prevalence of antimicrobial resistance genes was higher in the pig isolates of S. suis than in the human isolates and that the prevalence of these genes varied with serotype.

What are the implications for public health practice?
The data regarding S. suis antimicrobial resistance will help guide rational drug use in the clinic to better protect the health of humans and animals.

Streptococcus suis (S. suis) is an important zoonotic pathogen that apart from causing huge economic losses to the global swine industry, can also cause severe illness and even death in humans. Antibiotics are commonly used to treat and control S. suis infections, contributing to the increasing prevalence of antimicrobial-resistant S. suis, which has attracted the attention of the global health community (1–3). Therefore, monitoring the prevalence of antimicrobial resistance-related genes in S. suis and studying its antimicrobial resistance characteristics will provide guidance for the clinical treatment of S. suis infections. In this study, S. suis isolates from 20 provincial-level administrative divisions (PLADs) in China were collected and analyzed from 2011 to 2019, together with the available S. suis sequencing data (with detailed host information) in the National Center for Biotechnology Information (NCBI) database, and a global surveillance of S. suis resistance was carried out according to several epidemiological dimensions. The results demonstrated that the prevalence of antimicrobial resistance genes in S. suis was generally higher in China than in other countries and that the prevalence was generally higher in the pig isolates compared to the human isolates. The prevalence of resistance genes varied with serotype; however, erm(B), a gene mediating macrolide resistance, and tet(O), a gene mediating tetracycline resistance, were both prevalent across different serotypes. The results of drug sensitivity experiments indicated a high and concerning level of antimicrobial resistance in the S. suis isolated in China. Therefore, public health practitioners should pay attention to the rational use of medicines, reduce the abuse of therapeutic drugs, and promote the scientific use of medicines in farming to protect the lives of animals and humans.

In this study, nasal swabs, lung, spleen, liver, and lymph nodes of healthy and diseased pigs from 20 PLADs across China were collected and analyzed. The analysis data were then combined with the S. suis sequencing data (with detailed host information) in the NCBI database. The samples were collected strictly according to the relevant standard protocols, as all the samples were collected using Eswab tubes containing culture media and then stored and transported appropriately to the handling laboratories using ice packs. S. suis isolation was performed as described in previous studies (4). Genomic DNA of S. suis was extracted using the Wizard Genomic DNA Purification Kit (Promega, Beijing, China) following the manufacturer’s instructions. DNA libraries were constructed using the KAPA HyperPrep Kit Illumina platforms (Roche, Basel, Switzerland) following standard protocols and then sequenced on an Illumina HiSeq X Ten platform (Annoroad, Beijing, China). Illumina sequencing reads for each isolate were processed using Trimmomatic with an average quality cutoff of 20 (2.3 million average reads per sample). Finally, the high-quality reads were assembled as contigs of at least 500 bp with SPAdes (with parameter–careful) (version 3.13.1, St. Petersburg
Academic University, https://github.com/ablab/spades). via the Unicycler (version 0.4.7, The University of Melbourne, https://github.com/rrwick/Unicycler) assembly pipeline (5). The quality of the genome sequences was checked using the default settings in QUAST (version 5.0.2, St. Petersburg Academic University, https://github.com/ablab/quast) (6). Identification of S. suis serotypes was performed using the protocol described by Athey et al. (7). Resistance genes were identified using the SRST2 Toolkit (version 0.2.0, The University of Melbourne, http://katholt.github.io/srst2/). Minimum inhibitory concentrations were determined by the broth microdilution method according to the recommendations of the Clinical and Laboratory Standards Institute guidelines (CLSI, 2015: M100-S25).

During 2011–2019, a total of 436 S. suis isolates were collected from 20 PLADs in China, including 271 isolates from healthy pigs and 165 from diseased pigs (Table 1). Upon analysis, all 436 isolates were identified as S. suis. Genomic analysis revealed 17–1,753 contigs per isolate, with genome sizes ranging from 1,949,027 to 2,642,630 bp and an average GC content of 41.12%. Additionally, 934 sequenced S. suis isolates with specific host sources were screened from 2,452 isolates in the NCBI database, including 461 isolates derived from humans, 129 from healthy pigs, and 344 from diseased pigs. Altogether, 1,370 S. suis isolates were obtained from China, Vietnam, Thailand, the Netherlands, the United Kingdom and Japan, and majority of them were obtained during 2011-2019. A total of 27 distinct serotypes were identified from the 1,370 isolates, with the predominant serotype being serotype 2 (n=686), which accounted for 50.1% of the isolates, followed by serotype 3 (n=75, 5.5%). Furthermore, 57 (4.2%), 54 (4.0%), 50 (3.6%), 32 (2.3%), 32 (2.3%), and 29 isolates (2.1%) were identified as belonging to serotype 9, 7, 4, 1, 8, and 14, respectively.

The predicted antimicrobial resistance genes using the SRST2 Toolkit (http://katholt.github.io/srst2/) in all 1,370 S. suis isolates indicated that the prevalence and number of antimicrobial resistance genes were diverse among the different serotypes (Figure 1). Among all the resistance genes, erm(B) and tet(O) were highly observed in all serotypes (Figure 1A). The newly characterized srpA gene, which confers resistance to streptogramin A, pleuromutilins, and lincomamides, was found in 60 isolates (4.4%), mainly in serotypes 2, 3, 4, 9, 12, 21, 25, 29, 30, and 31 (dominant serotype 2) (8). Further, the prevalence of antimicrobial resistance genes in the isolates from China was generally higher than that in the isolates from other countries. The prevalence of antimicrobial resistance genes in human isolates was lower than that in pig isolates (Figure 1C). Drug sensitivity results showed that the antimicrobial resistance rate of S. suis was the highest for macrolides (91.5%) and the lowest for β-lactams (3.9%–15.4%) (Table 2), consistent with the genomic analysis results of antimicrobial resistance.

### DISCUSSION

In this study, the prevalence of antimicrobial resistance genes in S. suis was found to differ among the isolates from different sources; the prevalence of these genes in S. suis was generally higher in China than in foreign countries, which may be related to

Note: Refer to the streptococcal drug sensitive threshold.
Drug resistance threshold (μg/mL): a≥16, b≥4, c≥2, d≥8, e≥1, f≥8, g≥8, h≥4.
Abbreviation: MIC=minimum inhibitory concentration.

because most human isolates were serotype 2 and the prevalence of antimicrobial resistance genes in serotype 2 was generally lower than that in other serotypes, though the serotype 2 isolates accounted for a large proportion of the population. In general, the prevalence of erm(B), which mediates macrolide resistance, and tet(O), which mediates tetracycline resistance, was high among the isolates from all sources; however, the prevalence of these two genes in serotype 2 was lower than that in other serotypes, although serotype 2 represents the dominant serotype of pathogenic S. suis. Tetracycline resistance in porcine streptococci has become a major problem worldwide and is closely related to the widespread use of tetracyclines in the pig industry. The antimicrobial resistance gene prevalence and the antimicrobial resistance phenotype of S. suis evaluated in this study indicate the problem of the antimicrobial resistance of S. suis in China to be prominent, and timely actions should be taken to avert an imminent crisis. The results further provide important guidance and reference values for clinical drug use.

The findings of this study were consistent with those of some previous studies. Hout et al. showed that among the 1,163 isolates of S. suis collected in the Netherlands during 2013–2015, 78.4% were resistant to tetracycline and 48.1% to clindamycin, with the resistance rate for β-lactams being less than 5% (9). Another study by Zhang et al. investigating the drug sensitivity of 421 S. suis isolates from China found that the antimicrobial resistance rates for tetracycline, macrolides, and sulfonamides were more than 60%, and the antimicrobial resistance rate for β-lactams was only 9.5% (10). Based on these results, β-lactam antibiotics can still be used as the drugs of choice for S. suis infections.

This study was subject to some limitations. While the isolates used in this study for genomic analysis covered most parts of China; the geographical locations of the isolates whose data was sourced from GenBank were not evenly distributed. In addition, most of the isolates from Vietnam belonged to serotype 2.

In summary, data of 1,370 isolates of S. suis from 6 countries were investigated for antimicrobial resistance and classified according to different characteristics for comparative analysis. The prevalence of macrolide and tetracycline resistance genes was the highest. The prevalence of the resistance genes varied with the source; it was lower in the human isolates of S. suis than in the pig isolates. Based on these findings, to limit the extensive spread of antimicrobial-resistant S. suis, a series of interventional policies are needed to address the impending antimicrobial resistance crisis and to develop appropriate dosing strategies for the different strains of S. suis with different hosts to protect the health of humans and animals under the “One Health” approach.
